THE symptom of sleep in cerebral tumours has not received much attention. One reason is that it has not been carefully distinguished from allied states, such as coma and torpor. In the *Archives Générales de Médecine* of June 20th Professor Raymond has published a valuable lecture on the subject. As points of distinction between sleep and coma he mentions that in the latter the pulse is large and strong and has the characters of the cerebral pulse, that the respiration is deep and often stertorous, and, the most important distinction, that the most powerful stimulation does not awaken the patient. But these differences are diminished when the coma is only slight—when there is a state of obnubilation or somnolence of greater or less intensity. Incomplete coma, like sleep, may last only a few hours and strong stimulation may awaken the patient, but there is not a true awakening as in the case of sleep, the patient comes out of the state of torpor only for an instant and does not quickly regain all his faculties. Professor Raymond relates the two following cases of cerebral tumour in which sleep was a prominent symptom. A domestic servant, aged 22 years, was admitted into the Salpêtrière Hospital at the beginning of January, 1905. In July, 1904, she was attacked with irresistible sleep and was taken to the Hôtel Dieu where "hysterical sleep" was diagnosed. She slept for three whole days and then *awoke spontaneously*. The limbs were stiff, there were frequent attacks of vertigo, and she continually staggered. In August there was slight improvement but in September the staggering increased, she complained of dizziness, and talked in her sleep. In October she improved again and in November she attempted to return to work but felt giddy and somnolent all day. There was at times incontinence of urine and fæces. In December she suddenly passed into a sleepy condition which lasted 24 hours. On awaking she was prostrated, suffered from headache, and answered questions with difficulty. This condition persisted at the time of admission to the Salpêtrière Hospital. On the following days she was in a state of hebetude. She took her food and slept well and seemed to understand partly what was said to her. At times urine and fæces were passed. The head was thrown back, the face was grimacing, the expression was stupid, and articulation was so defective that she could scarcely be understood. She complained of constant occipital pain, which was increased when the head was bowed. The gait was hesitating but not definitely ataxic or cerebellar. There were slight rigidity of the limbs, which was greater in the lower ones, and increased tendon reflexes. There were no stigmata of hysteria. Her mental condition was torpid and she acted like an automaton. On shaking her energetically she was aroused for a few moments and answered questions better and with improved articulation but in a few minutes she relapsed into her habitual somnolent state. On Jan. 26th she became comatose and the temperature rose to 105·8° F. She died on the following morning. The necropsy showed a sarcoma growing from the left side of the pons and two secondary nodules in the left subthalamic region. Professor Raymond points out that though the diagnosis of hysteria made before the patient was admitted into the Salpêtrière Hospital was natural he found no stigmata of hysteria. The sleep resembled neither coma nor narcolepsy. For, on the one hand, the patient could be aroused, and, on the other, the sleep was not profound but a condition of somnolence or continuous prostration. In the absence of any intoxication he was led to suspect cerebral tumour. In the second case a woman, aged 42 years, was admitted into hospital. She enjoyed good health until a fortnight previously, when she passed into a state of continuous and progressive somnolence. She was in a condition bordering on coma, soon became completely comatose, and died on the following day before a thorough examination could be made. The necropsy showed two sarcomatous tumours in the right cerebral hemisphere—the larger in the posterior part of the lateral ventricle and the smaller, which was apparently secondary, in the occipital lobe. Only a few cases in which sleep, as distinguished from the allied states of coma, somnolence, or torpor, has been observed as a symptom of cerebral tumour have been previously recorded. Janet has described the case of a French girl, aged 14 years, of a very neurotic family who went to America.[1] In June, 1891, she complained of fatigue and torpor. After 48 hours she became delirious and then fell into a profound sleep which lasted for a fortnight without interruption. No reply to questions could be obtained from her but from time to time she swallowed a little milk. She improved and was sent back to France. But two days after her arrival she again passed into a condition of sleep though less profound than before. When spoken to she answered and complained of headache and begged not to be disturbed. She vomited several times. She could walk but knocked against objects. There were right hemiparesis and hypo-æsthesia with intention tremor of the arm and leg and left facial spasm. Intelligence was retained but memory for recent events was lost. When left alone she relapsed into sleep, from which she could be awakened by shaking. She died on August 29th. The necropsy showed a "parasitic cyst" three centimetres in diameter at the apex of the sphenoid lobe. Soca has recorded a case of sarcoma of the pituitary body in a girl, aged 18 years, who slept for seven months.[2] The sleep was apparently natural and she sometimes awoke spontaneously. Every day she was awakened to take food. Professor Raymond points out that sleep is usually an early symptom, or the first symptom, in those cases of cerebral tumour in which it occurs and that often other symptoms are so vague as to render the diagnosis difficult. Sometimes periods of sleep are separated by longer or shorter intervals and later the sleep becomes continuous. In other cases sleep is continuous from the beginning to the end. The nature of the sleep varies: sometimes it resembles natural sleep and the patients readily awake and entirely recover consciousness; others are in a state of torpor from which they can be roused only for an instant by energetic shaking and even then there is intellectual obnubilation. Still other patients cannot be awakened even for an instant and their state borders on true coma. Further, the patient may pass through all these conditions.

VACATION COURSES IN BACTERIOLOGY AND PATHOLOGY AT KING'S COLLEGE, LONDON.

A course in clinical and practical bacteriology, suited to the requirements of medical practitioners and senior students —e.g., for the M.B. examination—will be held daily at King's College, London, from 10.30 A.M. to 1 P.M., commencing on Wednesday, July 26th, and ending on Saturday, August 5th. The course will consist of lectures, demonstrations and practical work; in the last-named the members of the class will make for themselves permanent preparations of the chief pathogenic micro-organisms and will carry out the principal manipulations employed in bacteriological investigations. The fee will be £3 3*s.* inclusive of materials and the like. Names should be sent as soon as possible to the Secretary or to Professor R. T. Hewlett. A course in clinical pathology will also be held on six afternoons from July 27th to August 4th, from 2 to 4.30 P.M. The course will consist of demonstrations and of practical work. The inclusive fee is £2 2*s.* If both courses are taken the inclusive fee will be £4 4*s.*

FATAL POISONING WITH SODIUM CHLORIDE.

In *American Medicine* of April 22nd Dr. C. M. Combs has reported an unfortunate accident which resulted in fatal poisoning by sodium chloride, a substance usually considered non-poisonous. No similar case appears to have been recorded previously. Vaginal oöphorectomy was performed on a woman, aged 35 years. Her general condition was good, the operation was short and simple, and no apprehension was felt as to her recovery. To prevent thirst and renal congestion 500 cubic centimetres of normal saline solution were ordered to be injected under each breast. By mistake a stock bottle containing an almost saturated solution of sodium chloride was used instead of the diluted 0·9 per cent. solution. The injection was given while the operator was making the final toilet of the peritoneum. Four hours later, when the patient was seen, she was unconscious. The mistake was ascertained when the stock bottle was found empty. The woman had received 1920 grains of sodium chloride. She remained comatose for six hours. Then she was maniacal and talked until death which took place 24 hours after the operation. At first the pulse was 190 and bounding; later it was too rapid to be distinguishable, and the respirations rose to 70. There were insatiable thirst, a slowly ascending temperature attaining a maximum of 104° F., and constant nausea. The vomit contained five grains of sodium chloride to the drachm. During the 24 hours 300 cubic centimetres of urine were excreted which contained 11 grammes of sodium chloride—a normal amount considered absolutely but large relatively to the quantity of urine. There was neither albumin nor sugar. The red blood corpuscles were shrivelled and crenated from exosmosis. Dr. Combs thinks that the rapidity of the pulse and respiration was due to an effort of nature to compensate for the diminished oxygeniferous powers of the corpuscles. The treatment consisted in keeping the patient in a continuous hot pack and allowing and even urging her to drink large quantities of water. The combined excretions (urine, sweat, fæces, vomit, and tears) appeared to remove nearly half of the salt.

The commissioner of public health for Brisbane reports that for the week ending June 3rd 1 case of plague occurred in Brisbane and 1 death from plague at Ipswich, near Brisbane, on May 31st. During the previous week ending May 27th no case of plague occurred in the district. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on July 7th states that for the week-ending July 6th there was 1 case of plague and 1 death from the disease. As regards the Cape Colony, the medical officer of health of the colony reports that for the week ending June 17th 1 case of plague was discovered, being that of a native male found dead at East London on June 15th. Plague-infected rodents were found at Port Elizabeth, East London, and King William's Town. At Hong-Kong, a telegram from the Governor received at the Colonial Office on July 10th states that for the week ending July 8th there were 21 cases of plague and 21 deaths from the disease.

His Royal Highness the Duke of Connaught, president of the hospital, who will probably be accompanied by the Duchess of Connaught and Princess Patricia, will perform the ceremony of opening the nurses' home at the City of London Hospital for Diseases of the Chest, Victoria Park, E., on Wednesday, July 26th, at 4 P.M.

The residue of the estate of the late Mrs. Hames, wife of Mr. G. H. Hames, F.R.C.S., of 113, Sloane-street, London, has been bequeathed to King Edward's Hospital Fund for London, subject to her husband's life interest. The residue will probably exceed £50,000.

The Archbishop of Westminster will deliver a sermon before the Royal Institute of Public Health on Sunday, July 23rd, at the new Westminster Cathedral. Medical practitioners are invited to be present in academic costume.

General Laurie's Bill to amend the Medical Act of 1886 in such a way as to admit of a more complete reciprocity between Canada and the mother country has passed the second reading without comments.

A short vacation course of 22 lectures and demonstrations will begin at the Post-Graduate College, West London Hospital, on August 10th, information concerning which can be obtained from the dean.

The total amount received at the Mansion House for the Metropolitan Hospital Sunday Fund up to Wednesday evening exceeded £50,000.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 14, 1827.

We have not deemed it a duty to bring the professional conduct of private practitioners before the public eye, unless there have been connected with it circumstances of peculiar atrocity, calculated either to scandalise the profession, or prove detrimental to the public welfare; and even in such cases we have hitherto refrained from publishing the names of the parties, unless they have appeared to answer for their misdeeds in some of our courts of law, or public offices of police. But we are not quite sure, that we are acting with equal propriety in exercising a similar delicacy on the present occasion, because the circumstance to which we have to call the attention of the profession, is one so truly disgraceful, so characterised by a base and cold-blooded disregard of human life and human happiness, for the sake of contemptible and paltry lucre, that any lenity displayed in exposing it, almost amounts to a participation of the crime. A correspondent, on whose veracity the most perfect reliance may be placed, informs us, that in one of the western counties, a person calling himself a *surgeon*, has recently *inoculated* with the *virus of small pox some* *hundreds of persons at five shillings a head*, thus attempting to perpetuate one of the most blind and besotted of prejudices against the immortal labours of JENNER, and to keep alive and extend the ravages of one of the most horrible diseases that ever afflicted the human race. To the individual in question we do not address one word, as he must be devoid of sense, as well as of feeling; but surely prudence demands that the public should be protected against the remorseless proceedings of such a relentless monster; and, in the absence of an EFFICIENT College of Surgeons, we are not aware that any measure other than an Act of Parliament, rendering inoculation for the small pox, without previous vaccination, punishable by fine and imprisonment, can prove an effectual safeguard.

This subject demands the earliest attention of Parliament.[1]

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE FELLOWS' DINNER.

THE second annual Fellows' dinner was held at the College in Lincoln's Inn-fields on July 6th, after the meeting of Fellows for the election of members of Council. Nearly 100 Fellows were present, Mr. JOHN TWEEDY, the President, being in the chair. Many present and past members of the Council were present, among the senior Fellows being Mr. Thomas Bryant, Sir Thomas Smith, Colonel J. G. Pilcher, I.M.S., and Mr. T. W. Nunn.

The PRESIDENT proposed the toast of "The King" and after this had been duly honoured it was followed by the toast of "The Queen, the Prince and Princess of Wales, and the other members of the Royal Family." In proposing this toast the President mentioned that the Queen had paid a private visit to the museum in February last and that she had inspected all the museum and had expressed herself as very pleased with all she had seen and said that she hoped to revisit it on some future occasion.

The PRESIDENT then asked them to drink to "The Fellowship of the Royal College of Surgeons of England." He said that the toast list was purposely short, as it was wished to make the gathering somewhat of the nature of a conversazione and it was hoped that at the close of the dinner the Fellows would adjourn to the next room and spend their time in conversing with one another. At the Fellows' dinner last year he had mentioned that two of the original Fellows were still surviving, but even while he was yet speaking the spirit of John Birkett was passing to its rest and only a fortnight later died the other, Sir John Simon. Then Luther Holden became the senior Fellow and he died a few months later. Each of these Fellows in turn was the senior Fellow and each represented one of the three great branches of science with which the College is connected. Holden represented anatomy, especially in its relation to surgery; Birkett represented surgery; and Simon represented the science of hygiene. Throughout the world the Fellowship of the College was acknowledged to be the highest test of surgical knowledge. At present the Fellows were increasing in numbers by some 50 a year, but he thought that in the future the number of Fellows would become much greater. In conclusion, the President called upon those present to drink to the Fellowship of the Royal College of Surgeons of England and he asked Mr. Bryant and Colonel Pilcher to reply.

Mr. BRYANT said that he was glad to have the opportunity of replying to the toast, as he wished to present to the College a loving cup. For some years there had been held dinners of the Fellows but those dinners had not been held in the College. When the Council had decided to have an annual Fellows' dinner in the College buildings it was thought desirable to discontinue the other dinners. There was, however, in the hands of the secretaries a sum of some £80 and at first there had been some difficulty in deciding what to do with it. The permanent committee, which consisted of Mr. F. W. Braine, Mr. C. C. Braine, Mr. Lowndes, and himself, had at length decided to purchase a loving cup and to present it to the College. He had, therefore, the great pleasure of presenting the cup to the President on behalf of the College.

The PRESIDENT accepted the gift in the name of the College and the cup having been filled with wine was sent round, the President handing it first to Mr. Bryant, with the following words: "This cup contains a wine of France with whose great school of surgery we are linked by centuries of historical association and by considerations of mutual obligation and respect. The wine is fortified with a spirit, the spirit of good fellowship, and it is sweetened with pleasant memories. I will now add the cordial—a hearty welcome and good wishes to you and everyone here present."

Colonel PILCHER also responded to the toast of "The Fellowship." He mentioned how high a position was held by the Fellowship of the College throughout India and the colonies, as well as in the British Isles.

Sir THOMAS SMITH proposed "The Health of the President," who was, he said, the cause of the institution of these dinners and no worthier representative of the College had ever filled the presidential chair.

The PRESIDENT, in acknowledging the toast, insisted that the greater part of the work had fallen on the shoulders of the honorary secretaries, Mr. C. T. Dent and Mr. G. H. Makins. He hoped that the Fellows would move into the adjoining room and view the specimens which had been added to the museum of the College during the preceding 12 months. This was done and for an hour an informal conversazione was held.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XX.[1]

SOME CONCLUDING SPECULATIONS.

The Sequel to the One-portal System.—The Corporations as the Examining Authority.—A British Academy of Medicine.—An Imperial Naval, Military, and Colonial Service.—A Ministry of Public Health.—The late Lord Salisbury on Moderation.

I MAY repeat in this last chapter what has been said already concerning the purpose of these articles. The desire has been rather to describe the existing condition of the medical profession than to suggest remedies for anything wanting in that condition. A vagueness of project in medical reformers has in the past much retarded such efforts as have been made to place the profession of medicine upon a better footing; and this has been brought about by disagreement as to what the actual evils are and what their actual dimensions, rather than by hesitation as to the necessary remedies. It is not to be wondered at when medical men have been themselves, as a body, so doubtful of their aims that the public have been equally so; but the want of sympathy manifested by the public has prevented fair play being given to schemes for the improvement of the status of the medical profession under which the public would have been the chief beneficiaries.

The various defects in the professional life of a medical man, especially in the public relations of that life, have been detailed at some length, in the course of which remedies have frequently become apparent, but no systematic scheme of reform has been advocated because, on good grounds or not, I am inclined to regard such schemes as visionary. The education of the medical student may become a definite and symmetrical thing, the quack may have his soaring wings clipped, the State may find a way to provide both medical assistance for the poor and sanitary supervision of rural neighbourhoods without relying largely on unpaid work—these things, not only may, but will, happen in course of time. But I cannot conceive that any Bill proposing to amend the Medical Acts at one swoop in a wholesale manner will receive serious discussion in the House of Commons. Medical reform will arrive piece-meal and the career of the medical man will be made smooth much in the way that an old city street is reconstructed to meet modern demands. There are here no wholesale demolition and no elaborate scheme of rebuilding. Some structures, which have become useless, are replaced by other structures better fitted for modern functions; a private house becomes a shop; a warehouse becomes a railway station; a narrow gut by the gradual placing back of one or other side of the street is transformed into a channel of symmetrical width with the rest of the thoroughfare; a few new public buildings make their appearance; and so on—what can be used remains in use, obsolete buildings which can be satisfactorily converted to other purposes are so converted, and what is of no good perishes; but all the old associations are not violently destroyed by the crowbar and pickaxe. Similarly the medical profession, in its domestic as well as in its public relations, can be adequately reformed by the gradual removal of abuses, by the introduction of improvements that are sorely wanted, and by alteration of the functions of institutions whose efforts no longer meet the demands made upon them. There is no need for violent and wholesale reorganisation of everything, but there is every need for a common understanding among medical men as to what are the things that in the public interest most call for reform, for common endeavour to get such reform carried out, and for the enlightened sympathy of the public in the work.

---

[1] Excerpt from a leading article.

NOTE.—In a letter published in THE LANCET of August 4th, 1827, "Veritas" states: "I regret to say there are some practitioners in the environs of this great metropolis, who are doing daily, *under coverture*, what this person has the greater manliness and honesty to do *openly*, and probably under the persuasion that he is acting right."

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI. XVII., XVIII., and XIX. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), May 6th (p. 1218), 13th (p. 1287), 20th (p. 1375), and 27th (p. 1449), and June 3rd (p. 1533), 10th (p. 1584), 17th (p. 1657), and 24th (p. 1741), and July 1st (p. 43) and 8th (p. 87), 1905, respectively.

It is also necessary for practical reasons that the medical profession should formulate all demands for the betterment of existing circumstances with moderation and should recognise freely such improvements as have taken place. To do otherwise induces inactivity in those of the medical profession who would work for the betterment of their order, while influential people outside the medical profession take leave to regard medical men as unjust grumblers, for whom it is no good to try to do more as it is not allowed that anything has been done at all. I feel that anyone who has read these chapters in THE LANCET might be inclined to sum them up roughly as a mass of grumbles—grumbles about money, grumbles about status, grumbles about education, and so on—but the scantiness of the suggestions that have been ventured for the alteration of the circumstances complained of should show that I have not endorsed the view that the medical profession is in a very unfortunate plight. The medical profession has steadily progressed in learning during the past 50 years—this cannot be gainsaid—while as a whole the progress has been no less marked in moral and social standing. The princes of medicine have enjoyed always the esteem and consideration of the public, but this has not necessarily been the case with the medical profession as a whole. But there are more medical men to-day who are thoroughly well-educated cultured gentlemen than there were ten years ago, and every decade for the last half a century has witnessed a steady levelling up commensurate with the rise in the knowledge and culture of the public. The Latinity upon which the Fellows of the Royal College of Physicians of London were wont to pride themselves may have lost some of its finish, but this fact is surely counterbalanced by the disappearance of the apothecary vendor of tooth brushes and perfumery. What if other professions have arisen whose followers are also men of education and scientific learning? Nothing can force into the background the position enjoyed by the really well-equipped medical man, and too much importance must not be attached to the fact that the public appears generally ready to underpay the medical man. The misapprehension of professional aims under which this occurs will disappear and a steady effort should be made to bring this about as soon as possible.

Leaders have been lacking to the cause of medical reform who were ready with practical measures to meet existing conditions. There have always seemed to be two classes within the profession, a class who, through apathy or selfishness, "care for none of these things" and a class who are so acutely alive to certain of the grievances under which the medical profession lies as to be unable to see any compensating advantages or to hope for any amelioration of their plight. Such division of aims and interests has been particularly harmful in the past but recently there have been many signs that a better state of things is approaching, for I disregard those who affect to see in all hospital staffs and public vaccinators the deliberate enemies of the general practitioner. At the same time the absolute necessity that medical men should themselves agree upon what is wanted before raising their voices in any demand is becoming recognised, and as much may be said for the advisability that only such measures of reform should be demanded as are demonstrably for the public good. Moderation in what is sought under the name of medical reform does not imply any half-heartedness in the belief that such reform is required or any abstention from further demands in the future. Certainly, let us look forward to the time when all grievances whatsoever will be removed and all hindrances to a perfect understanding between the public and the medical profession will be swept away. This time will be a time when other professions besides the profession of medicine will be carried on upon ideal terms; when some such perfect unanimity between classes prevails as is usually depicted in the literature of the Utopias. Between this ideal future epoch (when, by the way, the public will need of medical men rather their advice as to prevention than as to cure) and the present day there is room for the free play of evolution, and because for the moment little is asked for it does not follow that there is but little that calls for accomplishment.

Take the one-portal system for example, the arguments for and against which were weighed in the preceding chapter. It has been over and over again insisted that the institution of a one-and-only entrance into the medical profession would be a valuable reform. But at the present moment any movement towards such a reform would be resisted in all probability by the medical corporations, certain of whose functions would thus be superseded. The time will come when the corporations will be recognised by everybody to have finished their work as educational bodies. Already the competition of the provincial universities is pressing them hardly, and whereas the universities are young and will grow in strength and multiply in number there seems no particular motive force upon which the corporations can rely to strengthen their position. As Professor Churton Collins has recently pointed out, a revolution, the nature and extent of which have been very imperfectly apprehended,[2] has during the last 15 or 20 years been profoundly affecting society in this country, especially in that stratum from which medical students are chiefly drawn—the middle or lower middle class. The tastes, the studies, and the aspirations which but a few years ago were peculiar to a small minority are now shared by the multitude. To go back a little further, 50 years ago there were in England and Wales only two Universities discharging the real functions of a university—the two mediæval foundations of Oxford and Cambridge. These two Universities then received annually about 2000 undergraduates. To this total a handful of students at Durham must be added, the foundation of the University of London not being taken into account, for an examining board, however high its standards and however extensive its imperial aspirations, cannot ever be a university. Mark the difference to-day. Each of the thirteenth century Universities welcomes 3000 students as undergraduates—Oxford had 3538 in 1904; the Victoria University has been divided so that Manchester, Liverpool, and Leeds now contain universities of their own; Sheffield will soon be joined to this list; there is a University of Birmingham and one of Wales with three constituent colleges at Aberystwyth, Bangor, and Cardiff; while the University of London has become a genuine university with teaching functions. Scotland, which has always been the quickest of the three divisions of the United Kingdom to see the great value of popular university education, will be forced by competition to do even better than its own good deeds; Ireland presents a problem to those interested in higher education which cannot wait much longer for its solution. At a rough estimate it is probable that where 50 years ago there were 2000 university students working upon the narrowly specialised lines laid down by tradition, there are now some 20,000 students whose education is conducted towards perfecting them for the various higher walks of life.

The significance of all this cannot escape the many learned and able men who are in authority over the medical corporations. They must see that among the most important faculties in the new universities are the faculties of natural science and medicine, and they must be aware that as time goes on, and as a university education comes to form part of the national life of the class whence medical students are drawn, every medical student will go to a university as naturally as he goes to his bath, he will proceed to take a medical degree as inevitably as he has his hair cut, and he will be in no more need of a qualification from a medical corporation than of an Indulgence from a Pope. The corporations will then be seen to have discharged their educational functions, but it is, to say the least, doubtful if that day has yet arrived, while it is pretty certain that the heads of the corporations are not likely to respond cheerfully to an invitation to commit suicide. The one-portal system will have its chance of securing Parliamentary support when its introduction will not damage existing institutions and when those institutions have found under altered conditions an altered scope for their activities. For the corporations will have their functions, even though the unanimous resort of all young men *in statu pupillari* to a university may make the possession of the hall-mark of a corporation unnecessary. There is the great examining function. We have seen how important the careful examining of medical students is, and the disastrous part that is played by the element of chance in the results can only be minimised by the selection of good and competent examiners. The corporations might well provide under a one-portal system all the examiners in medicine, surgery, and obstetrics who would be required by the General Medical Council or the Privy Council. The present position of the Royal College of Surgeons of England and the Royal College of Physicians of London is mainly that of an examining body—I take these Colleges as examples because the holders of the diplomas of their Conjoint Board are so numerous and because the examinations of that Board are so admirably devised and conducted. The Colleges receive a great deal of money from students and spend a great deal of money in examining students. Beyond the joint support of a laboratory, where the excellent work of the Cancer Research Fund is being carried out, and the maintenance and preservation of the Hunterian Museum by the Royal College of Surgeons of England they do not really do much more work that is of living importance and this work could be done if their diploma-granting function ceased. A Member of the Royal College of Surgeons of England is as likely as anyone else on the Medical Register to be sweated by a medical aid association, to be blackmailed by a hysterical patient, or to be browbeaten by a coroner. His corporation does not attempt to take his part in any such professional troubles, but contents itself with accepting his fees and in return examining him and giving him an assay mark. If the corporations became the examining machinery for all medical students under a one-portal system it seems to me they would be doing the same kind of practical work that they are doing now, only in still more important circumstances. In such a scheme the universities would provide the students, and the General Medical Council or the Privy Council, in looking for independent examiners, would naturally turn to the corporations. The examiners would be university graduates belonging, as the examiners now do, to the class that has aspired from the beginning to leadership in the profession. They would be the teachers in the big schools and the honorary staffs of the big hospitals, and they would qualify as examiners by taking the high honour diploma of one of the Colleges. The Royal Colleges would come to consist of the Fellows carrying on the examination work of the country and of those graduates of universities who, intending to belong to the front rank of their science, have qualified themselves to accept examinerships. The income of the Colleges would be less but so would their expenses, and, in my view, their position would be in no way lowered from that which at present they enjoy. They would represent the fine flower of the medical profession—all that is best, most ambitious, and most learned of that profession—and they would be at once recognised as the centres of medical thought. It would be an honour to belong to them.

---

[2] The University Review, May, 1905, "The Education of the Citizen."

I do not want to be understood as prophesying exactly what will happen—no claim to such perspicuity is made—nor do I suggest that any great changes will come about immediately. My guesses at the future are so far rough that they concern principally the English Colleges. I am only attempting to show that, although at the present time the Royal Colleges are almost certain to object to any one-portal system as taking away from them their most valuable privilege (the President of the Royal College of Surgeons in Ireland has just taken exactly this line), there is no reason why, as time goes on, and particularly as the numbers of their pass-men drop off, they should not come to regard the one-portal system as actually constituting their safety. There can be no doubt that the competition for the diplomas of the Royal Colleges, especially in England, has already abated, and this shrinkage cannot go on without being felt. A return of the medical students to London in great numbers will make no difference, for it will only be brought about by an arrangement of the curriculum that will offer the London student a fair chance of obtaining a doctorate: an accession of medical students to London will not increase the demand for the diplomas of the Conjoint Board. All the Colleges have past histories of which they may be proud. They have done, and are doing, good work—everyone allows this who knows anything about them, and the line of general abuse that is followed by some ardent reformers will never be followed by the well informed. If their numbers go down—and some believe that the competition of the provincial universities may bring down their numbers very quickly indeed—they may be depended upon not to let themselves die without an effort. If their rank and file drop away they must increase the power and numbers of their honour-men and take any opportunity that offers itself for their important employment. The Fellows of the Royal College of Surgeons of England are just now largely increasing in numbers and with improved medical education this increase may continue, but it may not. At the present moment a man who aspires to a surgical post in many of the more important hospitals in England must possess the Fellowship of the Royal College of Surgeons of England. There are many more large hospitals in England than in Ireland and Scotland put together, and all the young men who hope for the principal surgical appointments must be able to style themselves F.R.C.S. Eng., Scottish and Irish candidates for these posts in England being very generally required to obtain the English Fellowship. The number of ambitious young men has much increased of late, and consequently the number of men who acquire the English Fellowship has increased, but it is not in the least certain that this increase can be counted on for much longer. The moment that the M.Ch. of the universities is recognised, as it is perfectly sure to be, as an honour degree, the hospitals will begin saying in their advertisements that "candidates for the honorary staffs must be Fellows of the Royal College of Surgeons of England *or* Masters in Surgery at one of the recognised universities," when the main *raison d'être* of the Fellowship, under existing conditions, will at once disappear. Confronted with these facts the corporations in all three divisions of the United Kingdom will, I think, be perfectly willing to help on a scheme for the institution of a one-portal system; their desire will be to find a way by which their position would be confirmed as a great and important one under the new *régime*. I believe that if the examining function were given to them everyone would be pleased in time. The function would not be taken away from the universities, for all the examiners would be graduates of universities, M.D.'s as well as F.R.C.P.'s, M.Ch.'s as well as F.R.C.S.'s. The corporations would thus come to consist of the most learned and representative men—young and old—in the medical profession, and, indeed, in an automatic way, would become a sort of Academy of Medicine. Why should they not? Why should not the Royal Colleges in each dominion of the kingdom be the Academy of Medicine for the country?

Now we are in the realms of imagination, doubtless, and yet this piece of evolution seems to me to follow logically and easily upon the delegation to the corporations of the examining function, while it responds undoubtedly to an admitted want. The waste of time, money, and endeavour that is implied in the multiplication of medical societies in London alone is enormous, and this fact is now being recognised by a strong movement towards amalgamation. The scheme that is under the consideration of the Royal Medical and Chirurgical Society, the Medical Society of London, and other associations is certainly a good one. It may be planned to serve the needs of the scientific world for many years to come, but we can none the less conceive it as only preparatory to the formation of a real British Academy of Medicine rising under the joint endeavour of the Royal Colleges and corporations. The Colleges would be the most natural centres in which a learned body—or groups of learned bodies—could hold meetings; nowhere better or more aptly could libraries and museums be housed, and the walls of the Colleges would form the natural background for the portraits of eminent members of the British Academy of Medicine. This would be particularly the case when the examining functions of the Colleges had made the honour diplomas of the Colleges a necessity for all those members of the medical profession who take an academic view of their professional life. This is frankly an anticipation of the future, an attempt to guess to what use, when the street is remodelled, certain splendid old structures might be put so that full value could be given to their dignified past and full use could be got out of them for a utilitarian—and equally dignified—future. A guess it is certainly, but not a wild guess if the propositions are allowed :—(1) that education at a university will soon become the invariable procedure of a medical student; (2) that consequently the corporations will lose their diploma-giving privileges; and (3) that they will be found to possess sufficient vitality to live under the altered conditions.

Imagination may be allowed to range for a moment over the developments that will take place in other divisions of medical practice. Surely sooner or later there will be no need to compare the merits of the Army Medical Service, the Indian Medical Service, and the Naval Medical Service to the detriment of one or the other, but each will form a branch of an Imperial Sanitary Service the functions of which in time of peace will be mainly preventive and the efforts of which in time of war or epidemic will be supplemented by its civilian *confrères*. Of such an Imperial Service a properly organised Colonial Medical Service would form an integral part and every quarter of the world would show a station in which the principles of sanitary science were strictly observed and from which in time of need expert assistance could be received by the community.

Similarly, there will surely be no need in a few years' time to compare the Poor-law service of England with that of Ireland, or the sanitary service of Scotland with that of England. As the public becomes better educated, as it recognises how much depends upon the observance of the laws of public health, we may expect a general consensus of opinion as to the advisability of a Ministry of Public Health the officers of which properly selected for special knowledge in preventive medicine, properly paid, and free from any hampering conditions, may safeguard the health of the country and watch over the interests of the sick poor. The sanitary service of the country ought not to be separated from the Poor-law service. They are one and the same thing, the care of the health of the sick poor implies the supervision of their sanitary environment. And the two services combined into one should be under a Ministry of Public Health, which would also relieve the Local Government Board of its responsibilities in respect of the introduction of disease from abroad and, indeed, all relations with foreign powers as to public health.

As a conclusion of this series of chapters in which an attempt has been made to give a synoptical view of the sociology of medicine, I should like to quote a few lines from one of the late Lord Salisbury's essays, in which he describes the position of the holder of moderate views. He says in an essay on the position of Poland :—

> There are few positions more embarrassing than that of men who hold moderate opinions in regard to questions upon which excitement is running high. They are obnoxious to the partisans whom they have left behind, and to the partisans of whose extravagance they fall short, and are regarded by each side as combining the demerits of an antagonist and a deserter. Each party equally despises the luke-warm zeal and time-serving temper which can only take up half a cause. The pursuer of the golden mean must be content with the intrinsic value of his immediate course, he will win no sympathy and must submit to be cast out as crotchety by every enthusiastic mind.

I feel that many who have the cause of the medical profession at heart will consider my conclusions in respect of reform to be inadequate. I shall be only too glad to learn that any more drastic measures are practicable; my moderation has not come from half-heartedness, but from a belief that the cause of reform is badly served by a perpetual bellowing for what never will be obtained. I have tried to urge the doing only of what can be readily done. But though I have been thus limited in what I have suggested as being immediately necessary for the removal of many of the disabilities of the medical profession, so as to make that profession more valuable to the public, I set no bounds to the possibilities of medicine as a profession in the future. The fact that after much complaining, after the recapitulation of a series of abuses, only a few suggestions for reform follow must not be taken to mean that a perfect condition of things will so be reached. On the contrary, I would have it understood—for I believe it—that the future which medicine has before it is an infinitely great one. The present disorderly state of the profession in the United Kingdom can be set aright in many particulars without any great difficulty; the men who practise under the improved conditions will be able to show a public, growing daily better and better instructed, how valuable to the community properly ordered and properly appreciated medical service may be. From this point advance should be by geometrical progression.

THE END.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9005 births and 3484 deaths were registered during the week ending July 8th. The annual rate of mortality in these towns, which had been 13·4, 12·9, and 12·7 per 1000 in the three preceding weeks, further declined to 11·6 per 1000 last week. In London the death-rate was 11·2 per 1000, while it averaged 11·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·9 in Bournemouth, 4·5 in Northampton, 5·0 in Wallasey, 5·8 in Tottenham, 5·9 in East Ham, 6·7 in Cardiff, and 6·8 in Hornsey; the highest rates were 16·0 in Newcastle-on-Tyne, 16·4 in Sunderland, 17·4 in Liverpool and in Bootle, 17·7 in Merthyr Tydfil, 18·3 in Warrington, and 18·5 in Tynemouth. The 3484 deaths in these towns last week included 388 which were referred to the principal infectious diseases, against 355, 348, and 371 in the three preceding weeks; of these 388 deaths, 133 resulted from diarrhœa, 122 from measles, 71 from whooping-cough, 27 from scarlet fever, 23 from diphtheria, and 12 from "fever" (principally enteric), but not any from small-pox. In Hornsey, Brighton, Southampton, Huddersfield, York, Swansea, and 11 other smaller towns no death from any of the principal infectious diseases was registered, while they caused the highest death-rates in Wolverhampton, West Bromwich, St. Helens, Warrington, Salford, Barrow-in-Furness, Sunderland, and Rhondda. The greatest proportional mortality from measles occurred in Willesden, Bristol, Wolverhampton, West Bromwich, Warrington, Barrow-in-Furness, and Sunderland; from whooping-cough in West Ham; and from diarrhœa in Liverpool, St. Helens, Warrington, Rhondda, and Merthyr Tydfil. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns. No fatal case of small-pox was registered either in London or in any of the 75 other large towns. The number of small-pox patients remaining under treatment in the Metropolitan Asylums Hospitals, which had been seven, six, and four at the end of the three preceding weeks, had risen again to five at the end of last week; two new cases were admitted during the week, against three, one, and one in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2499, against 2356, 2427, and 2473 at the end of the three preceding weeks; 354 new cases were admitted during the week, against 292, 325, and 334 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 189, 144, and 140 in the three preceding weeks, further fell to 90 last week, and were 45 below the number in the corresponding period of last year. The causes of 36, or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Nottingham, Salford, Bradford, Leeds, Newcastle-on-Tyne, and in 49 other smaller towns; the largest proportions of uncertified deaths were registered in Hanley, Birmingham, Liverpool, Bury, Hull, and Rhondda.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 15·7, 16·1, and 16·5 per 1000 in the three preceding weeks, declined again to 14·7 per 1000 during the week ending July 8th, but was 3·1 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 7·6 in Perth and 8·9 in Leith to 15·7 in Glasgow and 17·1 in Paisley. The 449 deaths in these towns included 26 which were referred to whooping-cough, 14 to measles, 13 to diarrhœa, three to diphtheria, and one to scarlet fever, but not any to small-pox or to "fever." In all 57 deaths resulted from these principal infectious diseases last week, against 74, 60, and 65 in the three preceding weeks. These 57 deaths were equal to an annual rate of 1·7 per 1000, which was 0·4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 29, 18, and 31 in the three preceding weeks, declined again last week to 26, of which 14 occurred in Glasgow, eight in Edinburgh, and three in Paisley. The deaths from measles, which had been 26, 18, and 17 in the three preceding weeks, further declined to 14 last week, and included nine in Glasgow and four in Edinburgh. The fatal cases of diarrhœa, which had been 15, 15, and 14 in the three preceding weeks, further fell last week to 13, of which six were registered in Glasgow, three in Edinburgh, and three in Aberdeen. The deaths from diphtheria, which had been one, four, and one in the three preceding weeks, rose again to three last week. The deaths referred to diseases of the respiratory organs in these towns, which had been 63, 74, and 68 in the three preceding weeks, further declined last week to 65, and were 23 below the number in the corresponding period of last year. The causes of 22, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17·2, 17·9, and 14·9 per 1000 in the three preceding weeks, rose again to 16·9 per 1000 during the week ending July 8th. During the past four weeks the death-rate has averaged 16·7 per 1000, the rates during the same period being 12·1 in London and 15·5 in Edinburgh. The 123 deaths of persons belonging to Dublin registered during the week under notice were 15 in excess of the number in the preceding week and included eight which were referred to the principal infectious diseases, against three, six, and seven in the three preceding weeks; of these, six resulted from diarrhœa and one each from measles and from scarlet fever, but not any from small-pox, diphtheria, whooping-cough, or "fever." These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being also 1·1 per 1000 both in London and in Edinburgh. The fatal cases of diarrhœa, which had been two in each of the two preceding weeks, increased last week to six. The 123 deaths in Dublin last week included 30 of children under one year of age and 30 of persons aged 60 years and upwards; the deaths of infants considerably exceeded the number recorded in the preceding week, while those of elderly persons showed a slight excess. One inquest case and one death from violence were registered; and 52, or more than two-fifths, of the deaths occurred in public institutions. The causes of eight, or nearly 7 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1905.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·8 per 1000 of the population, estimated at 4,684,794 persons in the middle of the year. In the three preceding months the rates had been 6·0, 5·6, and 6·2 per 1000 respectively. The lowest rates last month were recorded in Kensington, Chelsea, Hampstead, Holborn, Greenwich, and Woolwich; while the highest rates occurred in Hammersmith, Fulham, Shoreditch, Bethnal Green, Stepney, and Poplar. Small-pox was slightly less prevalent than it had been in the preceding month; of the eight cases notified during June two belonged to St. Pancras, two to Bethnal Green, and one each to the City of Westminster, Stoke Newington, Shoreditch, and Greenwich. The Metropolitan Asylums hospitals contained four small-pox patients at the end of last month, against 20, 16, and nine at the end of the three preceding months; the weekly admissions averaged two, against four, four, and two in the three preceding months. The prevalence of scarlet fever was slightly greater than in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Shoreditch, Bethnal Green, Poplar, and Stepney. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1997, 2152, and 2236 at the end of the three preceding months, had further risen to 2444 at the end of last month; the weekly admissions averaged 301, against 272, 266, and 302 in the three preceding months. Diphtheria was considerably more prevalent during June than in either of the two preceding months; the greatest proportional prevalence of this disease occurred in Hammersmith, Fulham, Stoke Newington, Bethnal Green, Poplar, and Lambeth. The Metropolitan Asylums hospitals contained 715 diphtheria patients at the end of June, against 788, 719, and 684 at the end of the three preceding months; the weekly admissions averaged 111, against 98, 83, and 89 in the three preceding months. The prevalence of enteric fever showed but very little variation from that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Kensington, Hammersmith, the City of Westminster, Hackney, Finsbury, and Bethnal Green. The number of enteric fever patients remaining under treatment in the Metropolitan Asylums hospitals at the end of last month was 78, against 68, 65, and 80 at the end of the three preceding months; the weekly admissions averaged 10, against 11, 11, and 14 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, St. Marylebone, Finsbury, the City of London, Shoreditch, and Deptford. The 28 cases of puerperal fever notified during the month included four in Camberwell, and three each in Hammersmith, Islington, Stepney, and Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending July 1st the deaths of 4349 persons belonging to London were registered, equal to an annual rate of 12·1 per 1000; in the three preceding months the rates had been 15·5, 15·1, and 14·0 per 1000. The rates last month ranged from 7·0 in Hampstead, 8·4 in Lewisham, 8·7 in the City of London, 9·2 in Deptford, 9·4 in Wandsworth, and 10·0 in Woolwich, to 14·2 in St. Marylebone, 14·3 in Finsbury, 14·4 in Poplar and in Southwark, 15·7 in Shoreditch, and 15·9 in Holborn. The 4349 deaths from all causes in London last month included 443 which were referred to the principal infectious diseases; of these, five resulted from small-pox, 155 from measles, 36 from scarlet fever, 36 from diphtheria, 117 from whooping-cough, 11 from enteric fever, one from ill-defined pyrexia, and 82 from diarrhœa, but not any from typhus fever. No death from any of these diseases was recorded in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Chelsea, Hampstead, City of Westminster, Lambeth, Deptford, Greenwich, and Woolwich; and the highest rates in Paddington, Fulham, Stoke Newington, Hackney, Holborn, Bethnal Green, Poplar, and Battersea. Of the five fatal cases of small-pox three belonged to Lewisham, one to Hackney, and one to Shoreditch. The 155 deaths from measles were 81 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Fulham, St. Marylebone, Stoke Newington, Hackney, Poplar, and Battersea. The 36 fatal cases of scarlet fever were nine fewer than the average for the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in Kensington, Islington, Finsbury, Wandsworth, and Camberwell. The 36 deaths from diphtheria showed a decline of 65 from the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE, 1905.

* Including membranous croup.

Hammersmith, Stoke Newington, Finsbury, Poplar, and Southwark. The 117 deaths from whooping-cough were 28 below the average number in the corresponding periods of the ten preceding years; this disease showed the greatest proportional mortality in Stoke Newington, Hackney, Holborn, Poplar, and Battersea. The 12 fatal cases of "fever" were only one-half of the corrected average number; two of the deaths belonged to Bethnal Green, two to Stepney, and two to Lambeth. The 82 deaths from diarrhœa were 30 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Fulham, Hackney, Holborn, Bethnal Green, Stepney, and Poplar. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 33 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 91 per 1000. The lowest rates of infant mortality were recorded in Hampstead, St. Pancras, Camberwell, Deptford, Lewisham, and Woolwich; and the highest rates in Paddington, Hammersmith, the City of London, Poplar, Southwark, and Bermondsey.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon C. M. Beadnell to the *New Zealand* on completing. Staff Surgeon F. W. Parker to the *Sapphire*, additional, for the *Sapphire II.* Surgeons: A. R. Schofield to the *New Zealand*; C. B. Fairbank to the Gibraltar Hospital and for dockyard and naval extension works.

ROYAL ARMY MEDICAL CORPS.

Captain S. Mason resigns his commission (dated July 12th, 1905). Lieutenant H. St. M. Carter, from the Seconded List, to be Lieutenant (dated July 2nd, 1905).

Lieutenant-Colonel E. Butt is appointed to the recruiting staff in Ireland, vice Colonel J. G. MacNeece, who takes up duty as Principal Medical Officer at Malta on promotion. Major C. R. Kilkelly, C.M.G., is appointed Governor of Osborne House, Isle of Wight, the convalescent home for officers of the Army and Navy.

MILITIA.

Infantry: 3rd Battalion the Dorsetshire Regiment: Surgeon-Lieutenant-Colonel D. Curme retires under the conditions of paragraph 55, Militia Regulations, with permission to retain his rank and to wear the prescribed uniform (dated May 27th, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major J. P. Massingham to be Surgeon-Lieutenant-Colonel (dated June 27th, 1905).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Hampshire: Surgeon-Lieutenant P. N. Vellacott resigns his commission (dated July 12th, 1905). 1st Monmouthshire: The undermentioned officer resigns his commission: Surgeon-Lieutenant J. Hurley (dated July 12th, 1905).

Royal Engineers (Volunteers): 1st Devonshire and Somersetshire: Surgeon-Lieutenant E. G. Stocker to be Surgeon-Captain (dated July 12th, 1905).

Rifle: 1st (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant C. W. Marshall to be Surgeon-Captain (dated July 12th, 1905).

THE MOTOR VOLUNTEER CORPS.

Charles Buttar to be Surgeon-Lieutenant (dated June 19th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

East Surrey Bearer Company: Major J. J. de Z. Marshall is granted the honorary rank of Lieutenant-Colonel (dated June 12th, 1905).

ROYAL ARMY MEDICAL CORPS: EXAMINATION OF MAJORS FOR PROMOTION.

A July Army Order states: For 1906 the special subject for the examination of majors for promotion to lieutenant-colonel, referred to in para. 5 (*a*) and (*b*), App. VIII.B. of the King's Regulations, will be as follows: *Subject* 5 (a)—*Medical history of the more important campaigns.* The medical history of the South African War as described in "Report on the Medical Arrangements in the South African War," by Surgeon-General Sir W. D. Wilson, 1904, Parts I., II., III., and IV., VIII. and XVI.; and appendices referred to therein. *Subject* 5 (b)—A general knowledge of the army medical services of other powers. The medical organisation of the Japanese army as described in the "Handbook of Medical Organisation of Foreign Armies, 1902," or the medical organisation of a foreign army, selected by the candidate, described within similar limits.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on July 11th, Sir J. N. Dick, K.C.B., R.N., being in the chair, the sum of £80 was distributed among the several applicants.

NATIONAL DEFENCE.

We would call our readers' attention to the debate in the House of Lords on July 10th on the motion of the Earl of Wemyss regarding home defence and especially to the forcible and decisive speech delivered by Earl Roberts on that occasion. Field-Marshal Lord Roberts has the experience and qualifications to entitle him, if any man has, to speak with authority on such subjects as Imperial defence and the needs of the army. He emphatically declared that the lessons of the war in South Africa had been forgotten; that our armed forces were now as unfitted and unprepared for war as they were then; and that the public was indifferent to the army and regardless of the fact that Britain was no longer a kingdom but an empire. We may add that there are, we fear, many persons in this country who are endowed with so little patriotic feeling and sense of national responsibility that they would be roused, but at the same time benefited, by reading an article in the *National Review* for June last entitled "Some Candid Impressions of England by a German Resident." While we do not by any means agree with the German resident in all that he says, we have, nevertheless, with similar candour to his, to confess that his contribution contains too much truth to be pleasant. Commenting on the speech of Earl Roberts, Lord Raglan, President of the National Service League, in a letter to us, says: "Let us remember that no Government can be expected officially to support a noble appeal for national duty such as that made by Lord Roberts unless the people themselves show that they are ready to respond. And there is no surer way of helping the great soldier who has rendered such signal services to the country than by joining the National Service League and thus forming that body of public opinion to which a patriot statesman can appeal."

OUR VOLUNTEER FORCES AND THE PHYSICAL STANDARD.

Things are not going well with the new army reform proposals. The War Office has, under a circular issued last month and amended under date July 11th, called for reports to be sent in by Oct. 1st as to the physical standard of the Volunteers. The War Office instructions to the medical officers of this force are to the effect that they are to make a strict examination into the physique of the men. The circular in question has apparently been issued because the Government professes to have decided that the Volunteers are not in reality wanted for home defence and that, taken as a whole, they are unfit or useless for oversea warfare. The immediate object in view is to ascertain the number of Volunteers on the strength fit for service abroad. This has opened up a very big and contentious question which will be certain to provoke a good deal of discussion. In the meantime the carrying out of the War Office instructions is a matter of some difficulty and entails much expenditure of time and labour if the medical inspections are to be carried out properly. Civilian practitioners, who are Volunteer medical officers for war purposes, naturally object to neglect their civilian practice in order to inspect several hundred men for nothing. Mr. Arnold-Forster will, no doubt, be able to throw some further light upon the intentions of the Government in regard to the Volunteers in the promised debate thereon, but he stated in the House on July 12th that it was not proposed to grant any special allowance to defray the cost of medical examination, although the matter was receiving consideration.

THE RUSSIAN RED CROSS SOCIETY.

The executive committee of the Russian Red Cros

Society has asked the Mayor of Moscow to send a representative to the committee formed in the society with the object of changing the statutes of the Russian Red Cross Society in order that its operations in peace time may be on the same lines as now—in time of war—so as to keep touch with all social bodies permanently.

THE WAR IN THE FAR EAST.

If one of the most elementary principles in war consists in learning all that can be possibly found out about the intentions of the enemy while studiously concealing all knowledge of your own from him, then the Japanese have shown themselves past masters in that art. What has been going on behind the impenetrable veil of their apparent inactivity of late we do not know, but there has been a relatively long lull in the military operations in Manchuria. This lull is very suggestive of the belief that some comprehensive and sweeping movement against the Russians on the part of the Japanese armies is being projected and will soon take place.

A telegram from Godsiadan (Manchuria) announces the death of General Timofieff, inspector of hospitals, who was wounded by a bayonet during the battle of Mukden.

Correspondence.

"Audi alteram partem."

SOME COMPLICATIONS OCCURRING IN PULMONARY TUBERCULOSIS, WITH REFERENCE TO PROGNOSIS AND TREATMENT.

To the Editors of THE LANCET.

SIRS,—There has been much discussion in the medical journals during the past few months as to whether sanatorium treatment is, or is not, worth while. This has led me to try, by careful study of the records of cases treated at Woodburn Sanatorium, Edinburgh, during four years (1899 to 1903), and by consideration of their after-history, to ascertain the causes of failure and the reasons for success. It is evident that the question can never be settled by giving definite statistics of so many "cured" per cent., for the numbers (if correct at the moment) would require readjustment in six months' time. All patients for years after their period of sanatorium treatment must be classed as "partially restored," but at the same time none of them are stationary in that class. The term "holding their own" too often means "losing ground." They are either gradually passing into the class of "failure, chronic invalidism, and fatal result," or they are slowly and surely progressing towards "perfect health," the term of "perfect health" meaning that the invading bacilli are dead or eliminated and that the patient is free from the danger of a possible relapse. To be sure that this is so implies more than to know that all signs of active disease have disappeared from the lungs. It implies more, even, than to know that the digestive organs are perfectly performing their functions and that the nervous and muscular systems have fully recovered their normal tone. These conditions always precede perfect cure, they are of value as indicating that cure is in good progress, but they do not, individually or collectively, give a guarantee that danger of a relapse is non-existent.

In considering the class of cases in which the treatment is a failure one must remember that in many instances it is found that the actual amount of invasion of the lungs at the time of admission gives small hope of any possibility of cure; in others, the general nutrition of the body is so reduced by continuous toxic poisoning, with consequent widespread degeneration, that it becomes impossible to restore nutrition and the specific resistance to the disease. As a result of these conditions various untoward symptoms have arisen, often simply the exaggeration of the ordinary symptoms of any ordinary case; or else complications have set in which are due to the involvement of other organs by spread of the infection from the primary disease in the lungs. In such cases the cure may not be impossible, but it will probably be long delayed. It is a recognised fact that an early case of pulmonary tuberculosis with no complications is comparatively easy to "cure." When there is merely slight consolidation in one or both lungs, with any of the classical attendant symptoms of cough, anorexia, emaciation, weak circulation, &c., probably the functional disturbance will be overcome by open-air methods in the course of a few months. In such a case the organic lesion remains for longer time, but it is inactive and is undergoing a slow process of elimination.

The symptoms which cause difficulty and delay in the restoration of the patient to complete health are all of them probably due to *the results of slow* and continuous toxic poisoning. By the action of this poison the tissues, particularly the muscles, are deprived of part of their nitrogenous constituents, becoming more or less devitalised and unable to perform their normal functions. A vicious circle is set up and the complications, which were only functional to begin with, become organic, with definite histological changes and alteration of structure. Dyspepsia, for instance, is nearly always present at the beginning of a tuberculous illness; when functional it vanishes after a few days of rest, fresh air, and easily digestible food; when it persists, *forming a serious obstacle to the assimilation of food* and the nourishment of the body, it should no longer be considered as functional but as an organic complication. It *then exists as chronic dyspepsia, which is evidenced by a* flabby, coated tongue and by a more or less dilated stomach. It is often associated with obstinate constipation. Poisoning of the nervous system is manifested by insomnia or by various hysterical symptoms which disappear as the general strength of the body is restored. Poisoning, with consequent wasting, of the muscular system is always marked and is widespread in its effects. It accounts partly for the languor and lassitude which are often the initial symptoms of the disease observed by the patient himself. It affects the muscular walls of the stomach and intestines, causing weak and irregular contraction, which in its turn gives rise to intractable dyspepsia and constipation. More important than all, it affects the muscular tissue of the heart and thus, if unchecked in its progress, it strikes sooner or later at the very life of the patient.

The knowledge that so many untoward symptoms are traceable to wasting of the nitrogenous constituents of the tissues gives the physician a sure basis whereon to rest a *successful treatment*, and a *therapeutic agent* of great value is ready to hand for its accomplishment in the administration of raw meat. Open-air treatment, *per se*, cannot be considered as an unfailing cure for pulmonary tuberculosis, but that it is much more effective when combined with raw meat treatment may be easily verified by trial. To obtain the desired effect the treatment must be carried out thoroughly. It cannot give good results if it is tried for a few days or weeks and then dropped. Success comes to those who can steadily maintain the treatment until the end is attained and the cure is completed. The old adage that "as we sow, so shall we reap," is true in this as in every other phase of life. Therefore we find that active tuberculous disease cannot be eradicated unless it be vigorously combated. Further, we find that in ratio as the application of the treatment is lax so will the recovery be slow, and in proportion as the application is thorough so will the improvement it brings be rendered more certain.

In the hope that these few observations will give fresh encouragement to some who think that the permanent results of sanatorium treatment have not fulfilled the promise of early days,—I am, Sirs, yours faithfully,

ISABELLA MEARS, L.R.C.P. Irel.,
Medical Superintendent, Woodburn Sanatorium,
Edinburgh.

July 3rd, 1905.

MEDICAL BARRISTERS.

To the Editors of THE LANCET.

SIRS,—In your last number you record the fact of five registered medical men being "called to the Bar" on July 5th. As it would be of great professional interest to secure a complete list of all "medical barristers" I have already succeeded in compiling the names of some six score. It is, of course, very much more common for medical men to become lawyers than *vice versâ*, but there are several examples of the latter procedure. Further I have not yet met with the name of a "medical solicitor." Should any of your readers be able to add to my list from the records either of the living or of the dead I should be extremely grateful.

I am, Sirs, yours faithfully,
STANLEY B. ATKINSON,
Honorary Secretary, Medico-Legal Society.
22, Albemarle-street, W., July 10th, 1905.

LEISHMAN-DONOVAN DISEASE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 3rd, p. 1484, there appears an article by Captain Leonard Rogers, I.M.S., on the Conditions affecting the Development of Flagellated Organisms from Leishman Bodies and their Bearing on the Probable Mode of Infection. The writer details the results of experiments on the behaviour of the Leishman-Donovan bodies in various media such as sterile and distilled water, degrees of tonicity in salt solutions, and under anaerobic conditions and those of hyper-oxygenation. These results are negative and, as he says, prove nothing. One observation he made, however, may turn out to be of importance in pointing to the channel of infection in man. He himself and others also have shown that blood diluted with water, to which sodium citrate has been added to prevent coagulation, shows after incubation in the cold that there is an increase in the number of, and alteration in the form of, these bodies, provided, of course, that they were present in the original blood. Captain Rogers now shows that by acidulating this citrated blood better and more luxurious growth is obtained and a larger number of flagellate forms appear than in citrated blood of neutral or alkaline reaction kept under similar conditions.

Now this is an interesting, and is very likely to prove to be an important, fact, but when this writer proceeds to build up on this and some subsidiary facts, to be mentioned hereafter, that on this account the disease is probably transmitted by a blood-sucking insect, I think it is perhaps rather difficult to follow him. Speaking of the rapid development of the organism in acid media, he says: "This striking fact strongly indicates the acid medium to be the optimum for the flagellation of the parasite and also points to the acid-containing contents of the stomachs of some blood-sucking insects as the place in which the parasite undergoes the extra-corporeal stage of its existence."

It is true that there is a strong precedent already established for supposing tropical diseases like this to be spread by the agency of blood-sucking insects. In the case of disease caused by malarial organisms, by piroplasma, by trypanosomes, by proteosoma and halteridia, blood-sucking flies or bugs have proved to be connected causally. It is natural, therefore, I say, that this agency should be suspected in the case of kala-azar and tropical splenomegaly, and this, indeed, may well turn out to be the case, but what I submit is that at present there is little warrant for believing this to be the case and other paths of transmission appear at least equally probable. Captain Rogers and other observers of proved capacity have directed their attention to such a possibility and the bed bug has from the beginning been suspected. The experiments directed to this end have, so far as I know, been negative and in the paper under review Captain Rogers fails to find any suggestive forms in the bodies of bugs fed on sufferers from kala-azar. In one experiment he mixed the blood from the splenic puncture containing the "bodies" with the stomach contents of recently-fed bugs but he found no development of the organisms, and all the conclusions which he is able to draw are the indefinite ones that "the experiments at least show that the conditions are not inimical to the continued life of the parasite, but that is all that can be said at the present time."

The diseases above enumerated, where transmission by insects is proved, are much more of the nature of primary diseases of the blood than Leishman-Donovan disease is. In all these conditions the parasites are found regularly and constantly in the blood and peripheral vessels but this is not so in kala-azar and its congeners. The Leishman-Donovan body swarms in the deep viscera, in the bone marrow, and is also found in some visceral blood-vessels and very markedly in the surfaces of ulcer of the intestinal tract and of the skin, but it is not found in the blood except occasionally as a late terminal infection and then apparently in the white corpuscles, a phenomenon rather suggesting phagocytosis than parasitism. If it is to be carried in its extra-corporeal stages by blood-sucking insects the infection must exist in the peripheral blood, either in an ultra-microscopic form, in which case it finds a probable parallel in yellow fever, or the parasite must appear in the blood-stream under certain unknown conditions in the life of the host (like filaria nocturna). There is no reason, however, to have recourse to either of these propositions without more proof. In this connexion I may say that although the parasite is readily found in the ulcers of the skin, yet I believe that neither bugs, fleas, nor mosquitos ever bite ulcerated surfaces or even inflamed parts. If the parasite infects the otherwise healthy subcutaneous tissues it might find its way into an insect during biting, but the presence of the body has not been demonstrated in healthy subcutaneous tissue. It has been proved, however, that the parasite develops in water and better in acidulated water, and from this, taken in conjunction with the fact that practically in all cases of tropical splenomegaly a discharge of parasites takes place in abundance from the ulcerated large intestines, it is not a very bold step to assume, or at least to suggest, that the intestinal tract is the natural source of infection. The flagella which form are organs of locomotion and not of penetration and suggest a plentiful fluid medium rather than the more viscid stomach contents of insects. Most flagellate bodies which exist as such in the blood lose their motility when taken into the stomach of an intermediate host; at any rate, I have proved this to my own satisfaction in the case of trypanosomes in the blood of the fresh-water tortoise and their subsequent behaviour in the stomach of the leech.

Drawing analogies between diseases of different types is unsafe but it is noteworthy that cholera, enteric fever, and dysentery, all associated with ulceration or denudation of the intestine caused by their respective specific germs, are all (at any rate the first two) transmitted by fæcal infection of water and so back by a direct path to the alimentary canal of man. If the growth of the bodies in acid fluids suggests the acid stomach contents of bugs, why should it not equally suggest the acid stomach contents of man or of many other animals as the natural goal for the further growth of the organism? Splenic enlargement is one of the most marked characteristics of the disease but that organ is in as close physiological connexion with the alimentary system as it is with the blood-forming system. Witness the almost constant infection of the spleen by the Eberth bacillus in cases of enteric fever.

One other point Captain Rogers adduces in favour of his bug transmitting theory, and that is by his observations in Assam on kala-azar, which tend to show that that disease is a house infection and, furthermore, that it was transmitted to some Europeans by their relations with native women suffering from the disease. But transmission by fæcal soiling of clothes, floors, or the dust of compounds or of the water-supply would be almost equally favoured by such intercourse, and these persons ran the risk of taking certain other diseases which result from propinquity and are certainly not transmitted by insect agency.

To sum up the evidence *pro* and *con.* for transmission by blood or water agency:—1. Leishman-Donovan disease is not a blood disease properly speaking, for the organism is not found under ordinary conditions in the peripheral stream. It is a tissue infection. 2. The parasites concerned have never, to my knowledge, been found in the bodies of bugs, mosquitoes, or other blood-sucking insects, though much attention has been directed to this point. 3. There is practically in all cases a large discharge of infective material constantly taking place from the ulcerated intestine and in many cases also from the surfaces of ulcers on the skin or in the mouth, by all of which paths (knowing the habits of the native of India) water infection is peculiarly favoured. 4. Bugs are ubiquitous in India. The disease, however, is commonest in the swampy water-logged countries such as Bengal, Assam, and Madras, and practically unknown in the drier countries of Bombay, the high plateau of Central India, and in the Punjab.

In conclusion, then, I submit that what scanty evidence there is goes rather to point to the transmission of disease associated with the names of Leishman and Donovan by water carriage than by the instrumentality of insects.

I am, Sirs, yours faithfully,
PERCIVAL MACKIE, F.R.C.S. Eng.,
Lieutenant, I.M.S.
Goona, Central India, June 22nd, 1905.

THE MEANING OF "CASUALTY" PATIENTS.

To the Editors of The Lancet.

Sirs,—In Table I. of the excellent "Hospital Sunday Fund" Supplement to your issue of June 17th there are some (apparent) anomalies in the last column. Thus Guy's, with only *two-thirds* of the number of out-patients, shows *four times* as many "accidents and emergencies" as the London. Again, the London Temperance Hospital, with the same number of out-patients as Poplar, has only *one-half* the number of "accidents," &c. And the Royal Free, with a smaller number of out-patients than the Metropolitan, shows nearly *three times* as many "accidents," &c. If this column is meant to show cases treated in the casualty rooms the above figures are of great interest as raising a doubt whether, in some institutions, "casualty" cases are *confined* to "accidents and emergencies" alone.

I am, Sirs, yours faithfully,

July 7th, 1905. G. F. S.

THE CHICAGO STOCKYARDS.

PROSECUTION OF THE BEEF TRUST BY THE UNITED STATES GOVERNMENT.

(From our Special Sanitary Commissioner.)

It would seem, judging by the scant news which the telegraph agencies provide, that the Government of the United States of America is really determined to fight the Beef Trust. This is not only intensely interesting and important from the economic point of view but it also affects the public health. Cheap, clean, wholesome food is a primary necessity. An inquiry was made by the National Department of Commerce and Labour and for more than two years various small prosecutions were instituted in the civil courts. The last thing has been the inquiry held by the Federal Grand Jury. The sittings of this jury lasted three months and more than 100 witnesses were heard. The result is that 18 of the leading Chicago stockyard and packing firms will be indicted on various charges, including "combination in restraint of trade, conspiring to monopolise trade, and illegally granting and receiving rebates." As most of the transactions have been done through the telephone it is difficult to get evidence. Yet it is a matter of common belief that what has been described as "a voice on the telephone" fixes the price of nearly 90 per cent. of the cattle sold for slaughtering and also regulates the price of fruit and other articles of diet. By abolishing competitive buying the price of the animals purchased by the slaughterers is kept down. By abolishing competition in the sale of meat its price is maintained at an unnecessarily high figure. If this sort of combination is allowed to continue the Beef Trust, which is now also dealing in corn, or some other similar combine, will control the price of every loaf of bread. On one side the farmer and the cattle breeder will be at its mercy and on the other side the public will be forced to pay for food any price which the trust chooses to charge.

It is not necessary to insist on the dangers to public health likely to arise from such a monopoly. It is obvious from the descriptions given of the Chicago stockyards that the Beef Trust is not to be relied upon in matters of sanitation.[1] Mr. Ogden Armour is reported to have made some sort of reply to these criticisms but this reply has never reached The Lancet Offices. The Chicago correspondent of the *Daily Mail* stated at the time when The Lancet reports reached America that Mr. Armour had said that "The Lancet article displayed woeful ignorance of packing-houses and did not offer any practical suggestion for the improvement of their condition." As Mr. Armour is likely to have read the articles in The Lancet it is very improbable that he ever made any such remark. Of course, The Lancet does not profess to be an authority on the technique of the packing-house business except in so far as the interests of public health are concerned. For the sake of the health of the 50,000 to 60,000 workpeople employed in the Chicago stockyards, for the cause of humanity in dealing with the cattle about to be killed, on behalf of cleanliness, and for the securing, and the preservation of, the purity of the meat about to be exported to all parts of the world, many improvements were suggested. At the commencement of the series of articles in question this fundamental proposal is made:—

> In Great Britain and all over Europe the feeling gains ground that private slaughter-houses should be abolished and model public abattoirs instituted in their stead, either by the State or by the municipality.

Then it is pointed out that had this been done at Chicago, even at the low rate of charges made at the Berlin municipal abattoir, the city of Chicago would now be in receipt of an annual income of about £1,000,000. But the article continues in the following words:—

> It will scarcely be believed, but it is nevertheless a fact, that at Chicago not only is there no municipal abattoir but there are no private abattoirs in the technical sense of the term. It is true that millions of animals are slaughtered annually but they are not slaughtered in slaughter-houses. For many hours I wandered about the stockyards and I saw many animals killed but nowhere could I discover the smallest trace of a slaughter-house. The animals were killed not in abattoirs but in mills or factories—huge, hideous, box-shaped buildings five and six storeys high.

Then reproductions of photographs were published showing some of these factories and showing also that there is plenty of vacant ground in the immediate neighbourhood where the public authorities could build proper public slaughter-houses. So the first and fundamental improvement suggested was that, for the killing of animals, slaughter-houses should be constructed. These should be public slaughter-houses built according to the sanitary and humane principles established by a federal law and controlled by federal inspectors. There should be a proper bacteriological laboratory and quarantine station, as at Berlin, with convenient and safe arrangements for the railway traffic, the landing of cattle, and disinfection of cattle vans, as at the Prussian State railway station of the Berlin municipal slaughter-house. Then there should be a destructor for the carcasses of diseased animals as at the Hamburg municipal slaughter-house, model stables as at Anderlicht near Brussels, and model rules for the conveyance of meat to the retail shops as at Brussels. These are a few of the improvements that were suggested, not as fanciful hygienic ideals, but as reforms which have been realised in practice and in each case it was stated where they might be seen in working order.

It would seem that Mr. Armour is either very badly served or very badly informed, for to pretend in the face of this that no improvements were suggested is preposterous. But worse than this, here in London, shortly after the appearance of the articles in The Lancet, at the chemical exhibition recently held at Covent Garden Theatre the agents of Mr. Armour exhibited the proof of the correctness of the statements made. They displayed at their stall a gigantic photograph of the Chicago stockyards and thus every visitor to the exhibition was able to see for himself that there are no slaughter-houses at the Chicago stockyards. Every visitor could see that such buildings as exist at the Chicago stockyards would be condemned in any country in the world where any law exists defining what a slaughter-house should be. The audacity of displaying such a photograph in London, where there are at least a few persons who know something about the subject, is a proof either of the most profound ignorance or of cynical indifference to the opinion of all who are capable of judging in such a matter.

Consequently if, as there is good reason to believe, the Government of the United States of America has come to the conclusion that the Beef Trust is a danger to the country from the economic point of view this is a good opportunity to urge that it also imperils the public from the health point of view. The Supreme Court of the United States has approved the decision of lower courts condemning one of the leading firms of packers, Messrs. Swift and Co., for conspiring illegally to fix prices; still this abuse continues. It seems as if convictions at law have little or no effect. Perhaps a Public Health Law abolishing private slaughter-houses would be more efficacious. In any case, the Government is as justified in defending the public health as the public purse and this seems the propitious moment for pressing forward both questions.

---

[1] The Lancet, Jan. 7th, 14th, 21st, and 28th, 1905.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University of Birmingham.

AT a meeting of the Council of the University of Birmingham held on July 5th, the Vice-Chancellor presiding, Professor R. Saundby, M.Sc., M.D., LL.D., F.R.C.P., was appointed the representative of the University on the General Council of Medical Education and Registration of the United Kingdom. Professor Saundby was also appointed a delegate to represent the medical faculty of the University at the International Congress of Medicine to be held in Lisbon in 1906. Sir Archibald Geikie, LL.D., F.R.S., has accepted the invitation of the Council to deliver the Huxley lecture in 1906. Dr. C. E. Purslow has been appointed Ingleby lecturer for the year 1906. Dr. A. Stanley Barnes has been appointed examiner for the Russell Memorial prize for the current year.

The New University Buildings.

The new University buildings are rapidly rising and an official visit was recently paid to them by the members of the court of governors and of the city council. They comprise a large central hall and three blocks devoted to engineering, metallurgy, and mining. The hall, in which degree congregations, other university functions, and examinations will be held, is possessed of considerable architectural charm; it has a length of 170 feet and a height of 77 feet. It is expected to be ready for use in about 18 months' time. In the construction of the three blocks the end which has been constantly kept in view has been to combine an adequate amount of practice with a sound scientific training. It is maintained that in consequence the period of apprenticeship may be reduced. The buildings include a power station which will supply the University with all the electricity required for lighting and for power purposes; a boiler house containing locomotive boilers, gas engines, and marine steam engines; an iron foundry and forge, with smith's hearths, anvils, tools, cupola, patterns, and moulds for casting; a pattern-making shop and a drawing office measuring 100 feet by 50 feet which is described by experts as the finest in Europe. The metallurgical department includes foundries for smelting steel and brass; a room for melting ores by electricity and furnaces for dealing with the ores of gold, silver, copper and lead; a chlorination barrel for the treatment of complex gold ores; and a cyaniding plant for demonstrating South African and similar metallurgical practice. A machine shop is provided for cutting up metals for analysis and for crushing ores preparatory to assay work as well as an experiment room in which there are shortly to be constructed wind furnaces and gas muffles. Special rooms are provided for the measurement of high temperatures, for the microscopical examination of metals, and for electro-metallurgy, including electro-plating. The work in the metallurgical department is of a nature that may require the attention of students by night as well as day. In connexion with the mining department an experimental coal mine has been constructed. It is 12 feet below the surface and the workings extend in all directions for something like three quarters of an acre, the "roads" on different levels being on a scale roughly about one-third of the actual dimensions. In it practical instruction will be given in underground surveying and levelling and in connecting surface and underground surveys. Mine ventilation, timbering, and the different systems of haulage will all be studied on the spot. The scheme of instruction will include both coal mining and metalliferous mining in view of the fact that many students come from India and the colonies. Some idea of the size of the buildings and of the nature of their equipment will be gathered from the fact that their estimated cost is £450,000.

The New Dental Hospital.

The new Dental Hospital was opened a week ago by Sir Oliver Lodge (principal of the University). He was accompanied by the Lord Mayor and Lady Mayoress, a distinguished company of medical men, members of the city council, and representatives of dental hospitals in London, Manchester, Liverpool, and Newcastle-on-Tyne. The cost of the building is estimated at £8500 and the equipment at a further £1500. Towards this, £8500 have been promised. The new building has a pleasing frontage of red brick with stone dressing. It consists of four storeys and special attention has been paid to the provision of the greatest possible amount of light. It is built on a site which slopes in such a way that an excellent north and north-east light is secured which cannot be interfered with by any other buildings. On the ground floor there are a general waiting hall and accommodation for the staff, also class room, students' room, and museum. On the first floor there are rooms for operations, with and without anæsthetics, also a lecture hall. There are separate recovery rooms for male and female patients. On the second floor there are filling and saving rooms, specially lighted and well equipped with operating chairs. There is accommodation for 50 chairs. The top floor possesses an up-to-date mechanical department and workroom for making artificial teeth and crowns. In a word, everything which is found in the best private dental surgeries is provided at the new hospital.

Is Birmingham to have a Natural History Museum?

In view of the fact that the council is at present deliberating how to allocate certain land in the neighbourhood of the municipal buildings the above question has been again asked and considerable correspondence has taken place in the press. Dr. Bridge, professor of zoology, addressed a long letter to the *Daily Post* urging the pressing need for such an institution. He emphasised the ethical no less than the educational value of nature study, he spoke of the means which it afforded for cultivating habits of observation and inference, and evidently knowing that members of city councils are apt to take a too utilitarian view of such matters he did not neglect to point out that designers and artisans might find much that would be suggestive to them in their work from a contemplation of animal and plant forms. It is greatly to be desired that the present movement may be successful. It is well known that there are many very valuable private collections in the city and it may be permissible to hope that in the course of time they will find their way to such a museum.

The Charity Organisation Conference.

Representatives of charity organisation and relief societies throughout the country held a few days ago a conference in Birmingham. The subjects discussed included the care of the feeble-minded, emigration, apprenticeship, health visitors under the town council, and coöperation with the clergy and ministers of religion. The general feeling of the conference was that much of the unskilled labour of to-day was due to the abolition of the apprenticeship system. The discussion on health visitors was opened by the medical officer of health who gave a most favourable report on their work. He asserted that hundreds of houses were kept in a cleaner and more wholesome condition as a result of the work of these visitors and that many hundreds of mothers were making an effort to feed their infants in a better manner and with more wholesome food. Beginning with four health visitors there are now 13 in Birmingham.

Re afforestation in the Midlands.

Considerable progress is being made by the Midland Re-afforestation Association in its admirable endeavour to restore the natural beauty to lands devastated by mining operations. 5000 trees were planted on pit mounds near Wednesbury last year and 42 acres of pit-bank near the isolation hospital at Moxley have been handed over to the association. The Walsall branch of the association lately visited several sites where tree planting on pit mounds had taken place in the past. Reeds Wood Park, now a beautiful sylvan retreat containing thousands of large well-grown trees with open spaces from which crops of hay are taken annually, was once a desolate series of spoil banks. Horsefield Gorse Wood, now a thicket of conifers and other trees, mingled with wild roses and brambles, was planted some 25 years ago on levelled pit-banks of which not the slightest indication now remains.

Health of Birmingham and District.

The case of small-pox to which I referred in my last letter, and which was only discovered after the patient had suffered from the disease for some time, has been accountable for eight other cases and there are now 14 patients under treatment at the isolation hospital. Fortunately, the disease is of a mild type. An epidemic of measles has broken out at Wolverhampton and some hundreds of children are affected. 11 schools have been closed and the authorities are now discussing the question of closing all the schools. The epidemic at Dudley seems to be declining, but not before it has claimed 74 deaths.

July 11th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Council of the Royal College of Surgeons of England.

AT a meeting of the Manchester and District Association of the Fellows of the Royal College of Surgeons of England held on July 8th the following propositions were passed:—

> That it is desirable that Manchester be represented on the Council of the Royal College of Surgeons. That Mr. G. A. Wright be requested to stand as a candidate for the next election.

Mr. Wright consented to stand and a subcommittee was formed to further his election.

Small-pox at Todmorden.

In THE LANCET of July 1st it was stated that a Todmorden tradesman threatened an action because his daughter had been taken to hospital as a small-pox patient when, as he contended, she had only got chicken-pox. Unfortunately for him and his family his contention was not valid, for now he himself, his wife, and another daughter have developed small-pox and have all been removed to the hospital.

The Langho Inebriate Reformatory.

Complaints have been made from time to time of the great cost of the Langho Reformatory and the small number comparatively among whom the cost is distributed. It is stated that now, however, more careful classification is being adopted, and the work of reforming the inebriates is said to be "full of hope. The heaviest task has been to maintain peace between the women, their tempers at times being quite uncontrollable and almost amounting to madness." At the annual meeting of the friends of the Fallowfield Retreat the relative cost was stated to be much below that at Langho, and nothing so outrageous in the behaviour of the women was mentioned.

A Holiday in an Isolation Hospital.

At Wigton an unusual arrangement is being made for the holidays of the workhouse children. They are to spend them at the rural district council's isolation hospital, which is situated in a wooded glen. This does not seem an ideal scheme till we are reassured by the statement that "it has not yet been used for the purpose for which it was built."

Health of the Port of Manchester.

The eighth annual report of Dr. A. M. N. Pringle, medical officer of health to the Manchester port sanitary authority, tells of more work done than in any previous year since the authority was established and of the absence of serious sickness. The actual number of cases, 159, is the highest, but "it is merely the inevitable resultant of the expansion of the trade of the port." The number of vessels steadily increases year by year and the number of seamen fairly equally with the number of vessels. "As each seaman may be considered as a potential case of sickness," it follows that the actual number of cases of sickness or injury must be on the increase. And "as the total amount of sickness increases the tendency to increase in any particular form of disease should also be in evidence. It thus arises that the danger of the importation of forms of infectious disease is steadily advancing." However, there have only been eight cases of enteric fever and one case of "supposed" scarlet fever. There were 29 accidents, including seven cases of drowning. 2621 vessels were inspected. During the month of June 224 vessels of all kinds were inspected in the port, 119 being found to have defective and insanitary conditions. Of these the large majority—109—were British and the rest were foreign.

July 12th.

BRISTOL ROYAL INFIRMARY.—The carnival which was held at the Zoological Gardens, Clifton, during the last week in June with the object of raising £15,000 to wipe off the existing debt on the Bristol Royal Infirmary has been most successful. It yielded a profit of £7500 and Sir George White, Bart., has given a similar sum, so that the infirmary is now free from debt.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Institute of Tropical Research: Generosity of Sir Alfred Jones, K.C.M.G.

Sir Alfred L. Jones (the chairman of the Liverpool School of Tropical Medicine) entertained Lord Mountmorres and a number of gentlemen at a dinner at the Palatine Club on July 3rd to inaugurate a new movement for the encouragement of tropical research in Liverpool, under the title of "The Liverpool Institute of Tropical Research." Tropical cultivation of plants, trees, and crops, together with stock raising, come within the purview of the institute. Under animal products will be embraced scientific information regarding meat, preserved food, honey, fish, &c. The vegetable foodstuffs department will include rice, maize, millet, and other tropical cereals. The draft constitution of the institute shows that the general direction of affairs will be vested in an executive committee composed of men of distinction connected with Liverpool, its university, and its trade. In all that concerns the scientific work of the institute the director, Lord Mountmorres, will be advised by a professional board, composed of the men of science who will direct the work of the various sections into which the institute is to be divided. The departments will be seven, as follows: Statistics and geography, economic botany, economic zoology, economic chemistry, economic geology, technics, and ethnology and native languages. Sir Alfred Jones expressed the opinion that the movement would succeed like the Tropical School of Medicine. He promised to contribute £1000 a year for four years and said he was sure that further assistance would be forthcoming. It was the dawn of a great movement, one which the Germans and the Belgians had set working long ago. The commercial community now possessed in Liverpool a modern university which was willing to help in every way to build up the prosperity of the city and he was delighted to see present so many of the University professors. They had already been fortunate enough to obtain the services of Lord Mountmorres who would be appointed the director of the institute. His lordship had already drawn up a practical scheme and given a little time he had no doubt the scheme would bear fruit in a manner that few now realised. Our tropical possessions were scarcely probed into. It would be the endeavour of the new school of research to inquire in every way into the natural resources of our tropical possessions. In Lord Mountmorres they had an observer who had made himself familiar with those possessions, who had furnished reports of the greatest value, and he felt sure that with such a man at its head the institute would have a brilliant future. Lord Mountmorres, in his reply, pointed out how a want of scientific knowledge had kept back our progress in the rubber industries. Reference had been made to the importance of applying science to the everyday needs of the community. Applied science had a place in the universities and it was the duty of the universities to come forward and to demonstrate their utility. In Liverpool the prominence of a knowledge of the tropics was evident and he felt certain that the movement would have the support of the community. Liverpool should have a bureau of information. It was not right that we should be continually referring questions relating to drugs, timbers, and rubbers to the Continent, Liverpool should itself possess all it required in that direction. Professor Herdman said that he believed most thoroughly in the possibilities of the tropics. He had had a fair experience of their possibilities in his pearl fisheries expedition. The white man was wanted everywhere. Another point which struck him was the competition to which the Britisher was subjected by the German and the Frenchman. Lord Mountmorres proposed the health of the host, which was suitably responded to by Sir Alfred Jones, who said that his watchword was "Study what you have got." As an initial step the institute has just sent a gentleman to Paris to obtain for Liverpool a mass of information not locally accessible. The institute will work in many departments in coöperation with other bodies on an international basis, a free exchange of scientific information being thereby effected.

The University of Liverpool.

The city council on July 5th agreed to the recommendation of the finance committee to renew the grant of £10,000 to the University of Liverpool during the current year. The representatives of the city council on the council of the University have reported very favourably on the work carried on at that institution and are convinced that the aim of the University is "not only to serve the highest interests of the students, but to advance directly the commercial and industrial prosperity of the city; and that the University is using the best methods to obtain those results."—Professor Herdman conducted a small party of members of the Biological Society through the new buildings in Brownlow-street on July 1st, wherein the natural history department is to be housed. The primary object of the inspection of the numerous rooms was to see the accommodation provided for the Biological Society. The general arrangements of the spacious rooms, which occupy the central block between the Hartley botanical laboratory and the electro technic department, were much admired. The comprehensive museum, lecture theatre, ample laboratories, aquarium, and work places for advanced students all evoked commendation. Lord Onslow is to open the building on Nov. 4th.—The ceremony of conferring the degrees gained at the University during the past year took place at St. George's Hall on July 8th. There was a large and fashionable gathering of ladies and gentlemen and the galleries were occupied by students who showed their traditional resourcefulness in contributing to the liveliness of the proceedings. The candidates entered the hall in processional order and were followed by graduates, members of the governing and teaching bodies, distinguished guests, and civic representatives, with the addition of Sir Joseph Wilson Swan who subsequently gave an address in connexion with the opening of the new electro-technic laboratory at the University. The Earl of Derby, K.G., in his capacity as Chancellor of the University, presided, and "in virtue of the powers vested in him" conferred the degrees in due form. Following upon the ceremony at St. George's Hall, Sir Joseph Swan, accompanied by the Earl of Derby and Vice-Chancellor Dale and a numerous company, drove to the new electro-technic laboratory in Brownlow-street and having been presented with a golden key by the architects formally opened the main door. The visitors made a tour of inspection and subsequently assembled in the lecture theatre to hear a short address from Sir Joseph Swan. Professor Marchant, who is in charge of the laboratories, proposed a vote of thanks to Sir Joseph Swan and said that it was particularly fitting that Sir Joseph Swan should open a laboratory intended to train people in a knowledge of all the developments of electricity because he was the first to make the incandescent electric lamp a practical success. The new laboratories are an outcome of the endowment of a chair of electro-technics by Mr. David Jardine in 1903. Mr. Jardine's gift amounted to £10,000, and for the purposes of building the University fund advanced £12,000 whilst the Lancashire county council contributed £1000.

Mill-lane Hospital, Liscard.

Dr. J. Oldershaw, the vice-chairman of the Wallasey health committee, opened a new pavilion at the Mill-lane infectious diseases hospital on June 30th. The new pavilion has accommodation for 20 beds, bringing the total number of beds up to 64. The hospital was opened in 1887 with one pavilion containing eight beds. In 1894 a second pavilion with 12 beds was added and five years ago the area of the site of the hospital was increased to over six acres. If required further additions can be made, bringing up the total to 124 beds. Dr. Oldershaw pointed out the care that had been taken in construction in order that there might be no crevices to afford lodgment for infection-bearing material.

Accident to Dr. Joseph Henry of Rochdale.

Dr. Joseph Henry, medical officer of health of Rochdale, met with a serious accident on June 27th Whilst driving a dog-cart in the neighbourhood of Sudden, near Rochdale, the horse took fright at some passing object and bolted. The efforts of Dr. Henry and his coachman were unavailing in stopping the animal in its headlong course. The trap collided with a lamp-post and Dr. Henry and the coachman were thrown out. Dr. Henry sustained a simple fracture of the right tibia, besides bruises on the face and other parts of the body. The coachman escaped with only a few bruises. Dr. Henry is happily progressing favourably.

H.R.H. Princess Christian and the Liverpool School of Tropical Medicine.

Her Royal Highness Princess Christian received the following members of the Liverpool School of Tropical Medicine at Schomberg House on July 1st: Sir Alfred Jones (chairman), Major Ronald Ross (professor of tropical medicine), and Professor Rubert W. Boyce (the dean of the school). The Princess, who is honorary president of the school, presented the Mary Kingsley medal, on behalf of the Tropical School, to Dr. Laveran of the Pasteur Institute, Sir Patrick Manson, and Colonel D. Bruce, R.A.M.C.

July 11th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Opening of a New Semi-convalescent Hospital at Cookridge.

THE opening of the new Robert Arthington Semi-convalescent Hospital at Cookridge marks an important step in the history of the General Infirmary at Leeds, the work of which it will greatly facilitate. The policy of which the opening of this hospital is the latest expression was experimentally entered upon some 19 years ago. It was found that the ordinary convalescent homes to which many patients were sent from the infirmary could not, as was to be expected, provide for those who required a considerable amount of nursing or for those who, having been operated on, required skilled dressing combined with the benefits of pure air. The authorities of the Cookridge Convalescent Home kindly placed one of their wards at the disposal of the infirmary and this was provided with a sister in charge and a staff of nurses. The results were so satisfactory that a citizen of Leeds, Mr. John North, very generously gave a sum of £5000 towards the building of the semi-convalescent hospital, known as the "Ida" Hospital and so named in memory of one of his daughters, which was built close to the Cookridge Hospital and which, during the last 17 years, has been of the utmost utility. It provides accommodation for 50 patients and is under the immediate charge of a resident medical officer, a sister in charge who acts as matron, and a staff of nurses from the infirmary. It is situated about five miles from the centre of the city, on the high ground which separates Airedale from Wharfedale. The supplementing of this by the hospital which has just been opened was rendered possible by the gift of £12,000 by the late Mr. Robert Arthington who gave the money to the infirmary authorities to build a hospital for women and children. A site was purchased adjacent to that on which the Ida Hospital stands and in this way the new hospital was able to be arranged practically as an extension of the old one, with which it is connected by a covered way. The kitchen and certain parts of the administrative department are common to both. Both hospitals are constructed on the same general plan of a central block, with two widely diverging wings, inclosing in each case a wide angle, opening in a southerly direction. There are extensive verandahs and for some years quite a number of the patients at the Ida Hospital have slept out of doors. There are also small wards, day rooms, and an isolation department in case of the occurrence of any infectious disease. The patients who are sent to these hospitals remain under the care of the honorary officer under whose care they were when in the infirmary. Hitherto the duty of visiting the hospital has devolved on the assistant staff, but provision has now been made for a more systematic and regular performance of this duty by the appointment of a special officer. The "assistant surgeon in charge of the Ida and Robert Arthington Hospitals," who must be a Fellow of the Royal College of Surgeons of England, is appointed for a period of ten years, and is during that time a member of the faculty (or honorary staff) which in Leeds carries with it a seat on the board. He visits the hospitals twice a week. As the first holder of this post the election committee has recently appointed Mr. J. F. Dobson, M.S. Lond., F.R.C.S. Eng. The following extract from the annual report will be read with interest by those who are concerned in hospital finance:—

> The chief reason which has induced the board to decide upon the development of semi convalescent hospitals has been economy. As medical and surgical science progress, a great hospital such as the Leeds Infirmary inevitably becomes more expensive, so much so that it is wasteful to allow patients in a convalescent stage to occupy the room provided in it. At the same time these patients may be too ill to be taken home and too ill to recover without constant nursing and medical and surgical attendance. The semi-convalescent hospitals are devised to meet this class and it is found that patients after reaching a certain stage of convalescence derive more benefit by being treated there than

at the infirmary, whilst the expense of their maintenance falls from 27*s.* to 15*s.* 5*d.* per week. It is believed that sufficient of this class will be found to fill the Robert Arthington extension and that the hospital will thus obtain an increase of its accommodation of 50 beds at less than two-thirds of the cost of a similar addition to the infirmary itself.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Quater-Centenary Celebration of the Royal College of Surgeons of Edinburgh.

OWING to the large number of those who have accepted the invitation to the evening reception of the quater-centenary celebration of the Royal College of Surgeons of Edinburgh which will be held on July 20th, it is now intimated that the gathering will be held in the Royal Scottish Museum, Chambers-street, instead of in the Royal College of Surgeons, as originally intended, and stated on the cards of invitation.

The Dangers of Shell-fish.

Dr. A. K. Chalmers, medical officer of health of Glasgow, in a report to the health committee says that during past summers it has been necessary to refer to cases of enteric fever occurring in association with the consumption of shell-fish by excursionists to coast resorts. In contrast with these occurrences there has been little local evidence tending to incriminate the trade customs of the local shell-fish gatherers. It was recorded, for example, in connexion with the Lochgilphead cases of enteric fever two years ago, that the regular gatherers at that place rejected such shell-fish as were regarded by them as "sick," because they lay on the surface; while, on the other hand, the visitors collected and ate these without hesitation, being unacquainted with the fact that the healthy mollusc of the species then implicated was to be found below the surface of the sand. There thus arises the apparent anomaly that while visitors sickened after consuming shell-fish gathered on the spot, no cases were traceable among the consumers of those despatched to Glasgow in course of trade. Recently, together with Dr. J. C. McVail, medical officer of Dumbartonshire, and Dr. R. MacNeil Buchanan, the city bacteriologist, he visited the Gareloch, where gatherers were employed sending shell-fish to the Glasgow market. The sewage of the neighbourhood discharges on the foreshore towards the northern side of the loch, while that portion between the houses and the burn separating the parishes of Row and Roseneath is a little further distant from the sewers. The distribution of the mussel over the foreshore is irregular, the deposits lying closer at some places than others, but the gatherers were quite alive to the business risk of disease becoming associated with the consumption of their gatherings and purposely abstained from lifting mussels from that section of the shore on which sewers, or the bulk of them at least, were discharging. Herein, therefore, lies the note which may serve as one of warning to excursionists, for while the regular gatherers thus restrict their operations they were told of irregular gatherings—sometimes for bait but chiefly by visitors—of mussels from the area of obvious sewage pollution. Information in sufficient detail was not forthcoming to enable Dr. Chalmers to say what distance from a sewage pipe discharging below high-water level would in all circumstances constitute risk of infection from shell-fish gathered in the neighbourhood, but the direction of tides and local currents would obviously influence the question. In general, however, it may be recommended to the occasional visitor who has no opportunity of studying the habits of the marine fauna, that it would be well that shell-fish should only be gathered after inquiry has been made as to those habits from the local gatherers. Dr. Chalmers suggests the desirability of an inquiry into the conditions present over the whole area of shell-fish layings in the Clyde basin with a view to marking off such as come within the "danger zone" of sewage pollution. Dr. Buchanan reports that of six mussels taken at random from the neighbourhood of a sewage pipe all contained bacterial evidence of sewage contamination. Of a like number taken from a spot beyond this three were similarly affected, as were also four out of six taken from a spot still further removed but probably subject to the influence of local currents. The committee has requested Dr. Chalmers to communicate with the clerks to the local authorities of Argyllshire, Ayrshire, Renfrewshire, &c., requesting them to have boards placed on the shores warning visitors of the dangers attendant on the consumption of the class of shell-fish referred to in the report.

Infantile Mortality.

One of the most notable works carried out by the health committee of Glasgow is that associated with the question of infantile mortality. It has recommended that the medical officer of health should be empowered to give a fee of 1*s.* to the first person who gives him notification of a birth in certain districts of the city. At present births must be registered within three weeks, and as a rule it is done at the end rather than at the beginning of this period. The first three weeks of a child's life are probably the most important. It is intended that at the earliest possible moment after notification a visit should be made by one of the female inspectors who could be of great service in giving advice. It is a startling fact that while during the past 30 years the death-rate in the city has been greatly reduced the infantile mortality is as high as, if not higher than, it has ever been.

Insanitary Houses in Peterhead.

At a recent meeting of the public health committee of the Peterhead town council a letter was submitted from the secretary to the Local Government Board inquiring what steps were being taken in connexion with the remarks of the medical officer of health and sanitary inspector in their respective reports for 1904 with regard to the houses condemned as unfit for human habitation, the insanitary condition of a number of the houses lying between the Seagate, Brook-lane, Longate, and Broad-street, and the disposal of house refuse, particularly in the Ronheads district. The several subjects having been fully considered it was resolved to remit to the sanitary inspector again to examine the area referred to and to report in detail, with a view to the committee taking such action as it might deem advisable, in accordance with the powers contained in Section 154 of the Burgh Police (Scotland) Act, 1892, and in the meantime to put in force the powers contained in the Police and Public Health Acts against all persons committing nuisances of the description indicated; and, further, the town clerk was instructed to issue handbills to be posted throughout the burgh calling the attention of the public to the matter and to bring the subject before the inspector of police.

Epidemic of Measles at Fort George.

A situation of gravity in military circles has been created by the outbreak of a serious epidemic of measles among the soldiers stationed at Fort George. At the present moment the barracks and military camping ground there are occupied by a large number of men, there being 600 of the 3rd Battalion Cameron Highlanders, 700 of the Black Watch (1st Battalion Royal Highlanders), and about 100 Seaforth Highlanders. The outbreak of measles began about the middle of June and a military officer who visited the place at the end of June states that when he was there there were four or five large marquees filled with men who were suffering from the disease. The whole place—barracks and camping ground—has been isolated and the men have been placed in quarantine, no one being permitted to enter or to leave the limits of the area The epidemic first broke out among the Cameron Highlanders, who were camped near the fort, but the disease has spread to the garrison companies.

Contagious Diseases in Aberdeenshire.

At a meeting of the executive committee of the Aberdeen county council on July 7th, Mr. M. Gordon of Newton, convener, in the chair—it was reported that since May 1st there had been six outbreaks of parasitic mange and no fewer than 29 outbreaks of anthrax, the latter embracing practically all parts of the county. In view of the danger of cutting up animals which die from anthrax and thus allowing the tainted blood to escape and to propagate the disease, Mr. Smythe of Echt suggested the desirability of asking the Board of Agriculture for powers to compel owners of stock, in the event of sudden death, to inform the inspector for the local authority rather than to call in the services of a private veterinary surgeon. It was ultimately decided, however, that the county clerk should prepare and circulate a leaflet drawing the attention of stock owners to the fact that in the event of sudden or suspicious death among their stock they were entitled to have the gratis advice of the inspector of the local authority on their notifying the latter the occurrence. It was agreed also to recommend the unty council to ask the Board of Agriculture for powers to nend the Aberdeenshire (Parasitic Mange) Order of 1903 the following effect:—

(1) That all affected animals be detained at the place at which the ıbreak occurred until they are cured, with a provision for change the place of detention where necessary; and (2) that the movement other animals out of premises where the disease exists shall only be lowed subject to the animals being washed over with a proper disfectant before movement.

IRELAND.

(*FROM OUR OWN CORRESPONDENT.*)

The Belfast Workhouse Children.

AT a meeting of the Belfast board of guardians held on uly 4th a motion was carried to the effect that the nembers were in favour of the removal of the workhouse hildren from the workhouse grounds. Unless this were one, so placing the school buildings at the disposal of he guardians, a new children's infirmary would have to be provided. What is contemplated is the establishment of schools, as is the custom in England and notably in London, for the training of workhouse children.

The Belfast County Court-house.

The summer assizes open at the court-house, Belfast, this week and the high sheriff of Belfast (Dr. Henry O'Neill) finds that, from a sanitary point of view, the building is in an "infinitely worse" condition than it was in March last when the grand jury, common juries, and the Bar passed special resolutions drawing the attention of the judges to the matter. The work, long delayed, has been entered upon but it should have been taken in hand long ago and completed without a rush in time for the assizes. The Antrim county council has decided to expend a sum of £13,650 to provide for increased accommodation in the court-house, as agreed upon by county Antrim and the city of Belfast, both of which use the building for holding their respective assizes.

Lightning Catastrophe near Lurgan.

On the evening of July 9th the north of Ireland was isited by a severe thunderstorm and a flash of lightning ruck the pole of a tent belonging to the Irish Christian Vorkers' Union at Annaghanoon, near Donacloney, in the eighbourhood of Lurgan. As a result two men in the udience were killed and some 35 persons were injured. en of these received burns, some of which resembled the arks which would be inflicted by an ordinary fire spark, hile others were larger but none of very great extent, and eyond the shock occasioned to the nervous system no erious injury has been sustained by any of these patients. ne of the female patients who for a time was despaired of recovering and it is remarkable that in her case, though he was so severely prostrated, no marks of burns appeared on e body. At the time of the occurrence the audience in e tent were standing and singing a hymn.

July 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Possible Case of Paget's Disease (Ostitis Deformans) cured by Antisyphilitic Treatment.

AT a recent meeting of the Hospitals Medical Society I. Jacquet showed a patient who gave a history of having ad 30 (*sic*) chancres of the penis in the course of one year. le then, following on an injury, developed a deformity of he tibia which exhibited the "sabre-blade" shape. The rogress of this disease was arrested by mercurial treatment. I. Jacquet asked his colleagues whether this was really a ase of osteitis deformans or whether it was simply a case f syphilis, the diagnosis being based on the history and the esult of the treatment. For his own part he inclined to he latter opinion.

Two Cases of Addison's Disease Successfully Treated by Adrenalin.

At the meeting of the Therapeutical Society held on June 28th M. C. Gulbenk stated that cases of Addison's disease in which much improvement had been brought about by the administration of adrenalin were not uncommon in medical literature. He had himself treated with adrenalin patients under his care who were suffering from this disease. Two of these patients were practically cured, the asthenia disappeared, as did the pains and the vomiting, while the general health markedly improved. M. Gulbenk then proceeded to endeavour to account for the constant failures mentioned by many observers. Some pathologists regard Addison's disease as a lesion of the great sympathetic nerve, others as a destruction or functional arrest of the suprarenal bodies. It is therefore probable that Addison's disease is merely a group of symptoms produced by these two lesions coincidently. A sort of vicious circle takes place; the destruction of the gland brings about degeneration of the nerve, and a nerve lesion brings about degeneration of the gland, so that the clinical features of Addison's disease are due to both these factors together. Such is the opinion of Lancereaux. If the glandular lesion is the predominant factor adrenalin acts well; if, on the contrary, the nerve lesion is predominant adrenalin is of little use. On the whole, the administration of adrenalin is a valuable aid in the treatment of Addison's disease, especially in those cases in which the suprarenal body itself cannot be administered, although this last substance when given raw has a much more powerful therapeutic effect than has adrenalin.

The International Congress on Infant Feeding.

The first session of the Congrès International des Gouttes de Lait will be held in Paris on Oct. 20th and 21st. The presidents are Dr. Variot, physician to the Children's Hospital, and Dr. Dufour, the founder of the "*goutte de lait*." Among the committee are Dr. Richardière and Dr. Boissard, physicians to the Paris hospitals, and sundry foreign medical men who have founded "*gouttes de lait*" in Spain, Belgium, Russia, and Switzerland. The secretaries are Dr. Roger, physician to the hospitals, Dr. Péan, and Dr. Grasset. The object of the association is well known—namely, to diminish the mortality among non-breast-fed children by supplying good and pure milk and by instructing ignorant mothers. Anyone wishing to take part in the congress should send his name, together with 20 francs, to Dr. Roger, 39, Rue de Berry, Paris, before Oct. 15th.

Some Figures of Diabetes.

M. Navarre recently laid before the Lyons Medical Society some interesting figures concerning the frequency of diabetes among railway engine-drivers and firemen. The figures gave the following results per 1000. Of engine-drivers and firemen 12·65 were diabetic; of guards and brakesmen, 13·10; and of other railway servants, 1·7. M. Navarre attributes the diabetes which is so constantly found among travelling servants to the continual shaking which they undergo. M. Lepine considered that in addition to the purely physical shocks, mental anxiety plays a large part in the production of the disease. He cited the case of an engine driver who developed diabetes within 24 hours of the train which he was driving having just avoided a collision.

Pneumotomy for Dilatation of the Bronchi.

At the meeting of the Surgical Society held on June 28th M. Tuffier read, on behalf of M. Antipas, the report of a case in which the latter had performed pneumotomy. The patient was a child, aged four years, who for three months had suffered from pulmonary infection with signs of septic infection and a cavity at the base of the lung. On incising the lung, the tissue of which was much thickened, a small cavity was found which was full of pus. This was drained and the symptoms of septicæmia were markedly less on the following day. Broncho-pneumonia, however, supervened and the patient died. Pneumotomy only seems to have made any progress since the invention of apparatus to obviate the retraction of the lung which occurs when the pleura is incised. Such apparatus has been invented by both Saurbruch and Brower. The results of pneumotomy for bronchiectasis are not very encouraging, but in recent infections of the lung it is useful. Thoracoplasty is perhaps better and is certainly a less severe operation. M. Antipas related the case of a youth, aged 17 years, in whom he resected three ribs on the side which tended to contract and in whom all febrile symptoms disappeared after the operation.

Venom in the Eggs of the Viper.

M. Phisalix has already shown that when the toad awakes from its winter sleep the eggs in the ovary absorb a certain quantity of the poison which is circulating in the blood and this poison plays an important part in the phenomena of heredity. At a recent meeting of the Academy of Sciences he read a paper showing that the same process takes place in the viper. The yellowish "*bouillie*" obtained from the ovules of the viper by crushing them and removing the limiting membrane is very toxic and kills animals into which it is inoculated with all the symptoms of viperine intoxication. It has all the properties of the actual venom, it will not dialyse, and is destroyed on exposure to a high temperature. The presence in eggs of poisons so characteristic as those of the toad and the viper gives reason for thinking that together with the mechanical phenomena of development there are also chemical phenomena the rôle of which must be essential in the formation of the organs and for the mechanism of heredity.

Sodium Citrate in the Therapeutics of Infancy.

At the meeting of the Society of Pædiatrics held on June 20th M. Variot referred to the extremely satisfactory results which he had obtained in infantile gastro-enteritis by the use of sodium citrate.[1] While not denying the eupeptic action which has been ascribed to this drug he considers that its chief value is its power of acting as an anti-emetic in the digestive troubles of bottle-fed infants or in those who, although suckled, vomit for no definite reason.

July 10th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

A Tropical July.

WRITING on June 26th in the midst of a tremendous storm, during which the flashes of lightning and the thunder peals were so frequent as well-nigh to be past counting, I shared the consolatory anticipation of many a Florentine that this grand atmospheric performance was but the prelude to a period of cool steady weather, particularly as the finale of the said performance was what Italians call a "*nubifragio*"—the bursting of a waterspout, which flooded the streets, engorged the mountain streams to torrents, and roused Father Arno himself out of bed to run a race along his banks out of all keeping with his usually staid, not to say retiring, behaviour. We little knew what was in store for us! In a few hours the heat became all too perceptible, even aggressive, and before the week was half through not Florence only but all Italy was lying supine under a temperature to which the directors of the meteorological observatories throughout the kingdom have with difficulty recalled a parallel. Returns from these observatories continued to tell a similar tale. In Rome on July 4th the thermometer registered 40·1° C., whereas the highest figure for the last 30 years was 37·6° C. According to Professor Palazzo, of the Roman Meteorological Observatory, there is no exceptional cause to account for the phenomenon. "It is," he says, "the barometrical situation that determines great temperatures. All over Europe the barometrical markings have been abnormally high—exceeding 760. In Italy the differences of pressure are small; hence we have either very faint air-currents or perfect calm, and it is precisely the absence of wind and the serenity of the sky to which we owe our high temperature. The sun's rays are continuously scorching the earth; in the clear atmosphere there is not a cloud to intercept them; the air is absolutely pulseless. Even through the night, cloudless though it be, the sky is not very transparent and therefore the nocturnal cooling-down is hardly perceptible. No extraordinary agency lies behind the present high temperature in Italy; it is simply a concurrence of causes all tending to that result." The Padre Rodriguez of the Specola Vaticana and the Padre Guido Alfani of the Osservatorio Ximeniano in Florence have given the same opinion, all of them looking to barometric depression from the Atlantic to modify the situation. Meanwhile the number of cases of insolation reported from town and country is appalling, till the population hardly dares to venture abroad. The noonday stillness of the great industrial centres is something solemn, even sepulchral, and if, by necessity, an individual has to pass from one point of the city to another he may be seen (as described by Manzoni) hugging the shady side like a figure in *basso-rilievo* or, like the figure of the man in the opening of Dickens's "Little Dorritt," making a plunge into the blazing piazza and striking out for the nearest landing place. Serous apoplexy occurring in the night when the patient is in bed is frequently reported, chiefly from the great cities where American bars for the retail of iced beverages have multiplied enormously of late years and where the engorgement of the circulation with liquids induces the "condition precedent" to the apoplectic stroke. As I write reports from the provinces notify a slight diminution of the heat, though the returns of insolation stand at about the same figure. We have yet to receive full and adequately checked statistics of a phenomenon which will make the year now passing an *annus mirabilis* in meteorology.

July 8th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of the Plague Mortality.

THE mortality from plague throughout India shows a rapid decline. For the week ending June 10th only 7486 deaths were reported as compared with 15,317 for the previous seven days. The Punjab had 5086 deaths, as against 9460; the United Provinces 955, as against 1785; Bengal 299, as against 661; Rajputana 349, as against 2449 (this extraordinary drop suggests some error in the returns); Bombay districts 345, as against 361; Burma 60, as against 85; Kashmir 56, as against 62; Bombay city 227, as against 346; and Calcutta 52, as against 84. The only place at the present moment where the disease seems to be spreading is Burma, where outlying districts from Rangoon have recently been attacked. Bassein has been declared an infected port. In the report for 1904 recently issued concerning the jails of the Punjab it is recorded that only one death from plague occurred, although the disease was raging in the province for three parts of the year.

The Prevalence of Kala-azar in Assam.

In a report recently published concerning the work of the dispensaries in Assam it is stated that the number of cases of kala-azar fell from 2534 in 1902 to 257 in 1904, but it is admitted that the diagnosis of the hospital assistants cannot be depended upon. Concerning this disease statistics are almost valueless, although it is probable that the mortality has not been so great in recent years as formerly.

Excessive Summer Heat.

During the past fortnight the summer heat in many parts of India has been excessive. In the Gangetic plain temperatures of from 100° to 114° F. have been frequent—the latter figure having been recorded in Allahabad and a temperature of 106° was registered in Calcutta. In the latter city the heat has been exceptionally oppressive and many deaths have been attributed to it. Large numbers of horses have been lost as well as draught cattle.

Cremation for the Parsi Dead.

There seems to be a move amongst a certain section of the Parsi community in Bombay to adopt the western method of cremation of the dead in place of the loathsome practice of exposing the dead to be devoured by vultures. The Hindu method of cremation by open wood fires is not supported. It is proposed to establish a Bombay cremation society on the lines of the Cremation Society of Bengal which was established in Calcutta in 1902. It is earnestly to be wished that the innovation may be taken up by the Parsi community, which, while so enlightened and far-seeing in some respects, is backward and exclusive in others.

Vital Statistics of Bengal.

A Government resolution on the report of the Sanitary Commissioner for Bengal for 1904 has just been issued. The birth-rate has been enormous—viz., 42·6 per 1000 for the whole province—and in Chota Nagpur division it reached nearly 50 per 1000. In the Hazaribagh districts the birth-rate exceeded 56 per 1000. On the other hand, the death-rate was high also—viz., 32·4 per 1000 for the whole province and over 35 per 1000 in many places. In Chota Nagpur division the death-rate was only 22·9 per 1000. The registration of births is hardly likely to be over estimated, but the registration of deaths is very probably under estimated. The infant mortality is put down at 187 per 1000 births but varies in different places, probably as much from defective registration as from the varying degrees of healthiness in districts. The heading of fever, under which so many deaths are recorded, covers a large number of diseases as well as of deaths of infants born feeble. Too much reliance should not be placed on Indian mortality statistics, especially with regard to the frequency of certain diseases, as the causes of death are in the vast majority of cases merely those given by the ignorant relatives. By Captain Rogers's researches in Dinajpur it was shown that out of 1000 deaths attributed to fever one-fifth were probably due to pneumonia, one-tenth to diarrhœa, one-ninth to pulmonary tuberculosis, one-sixteenth to dysentery, and one-fifth to other causes, leaving less than one-third as probably due to malaria. The Lieutenant-Governor has recently sanctioned a project for draining an area of 290 square miles and other schemes are in preparation with a view to lessen the prevalence of malaria. It is interesting to note that several of the municipalities of Bengal are becoming alive to the necessity of improved sanitation. There are 14 drainage schemes being prepared and others are under consideration. A great deal more might be done if progress in this direction was not left to municipal bodies but was taken in hand by a skilled sanitary board. At present such a body exists only to give advice—it has no power to command. Sanitary progress under such conditions must necessarily be slow.

June 23rd.

Obituary.

HERMANN NOTHNAGEL, M.D.,

FESSOR OF SPECIAL PATHOLOGY AND CLINICAL MEDICINE IN THE UNIVERSITY OF VIENNA.

UR Vienna correspondent has sent us the following brief preciation of the world-famous physician, Professor rmann Nothnagel. "Austrian medical science in parular, and that of the whole civilised world in general, have ffered a severe loss by the death of Professor Hermann Nothgel which occurred on July 6th from an attack of angina ctoris. He was in his sixty fifth year, having been born in ussia in 1841. He was educated at Berlin and Königsberg, nong his teachers being Traube, Virchow, and Leyden. In 366 he settled in Konigsberg as *privat-docent* and in 1870 e served as an army surgeon during the war, being medical fficer in charge of the hospital at Châlons-sur-Marne. He hen held various appointments at the Universities of Breslau. reiburg, and Jena, and in the year 1882 came the call to ienna. Here he served the University as professor of pecial pathology, therapeutics, and clinical medicine, besides eing director of the Medical Clinic. In his non-official apacity he built up a large practice, patients coming to him from all parts of the world, among them being various kings and two emperors. His contributions to medical literature were numerous and famous, amongst the best known being 'The Localisation of Diseases of the Brain' and 'Diseases of the Nervous System following Typhoid Fever.' Besides these he wrote a treatise on the Rhythmic Action of the Heart, a Text-book of Epilepsy, an exhaustive work upon Materia Medica, and edited the great work upon General Pathology and Therapeutics which was written by various authors under Nothnagel's personal supervision. His own contribution was the section on Diseases of the Intestines.

Nothnagel was the last of the great men who made the Vienna School of Medicine so famous, his chief predecessors being Hyrtl, Rokitansky, Billroth, and Skoda. For some years before his death he was aware that he was suffering from arterio-sclerosis and the last letter he ever wrote, composed only some two hours before his death, was addressed to his assistant at the clinic and contained exact notes of the course of his illness, of the rhythm and regularity of the pulse, and of his temperature. From these notes it is evident that he was fully conscious of the nearness of his end. As a teacher he was very successful and highly appreciated by the students. He was not only eloquent but his lectures were eminently practical, teaching his hearers not only to see but to observe and to draw conclusions from their observations.

"His body was buried on July 9th, an enormous crowd attending the rites. All the highest dignitaries of Vienna, representatives of the Government, of the University, of the medical societies and the colleges, took part and his remains were laid to rest amidst universal expressions of regret."

ALFRED BOWYER BARTON, M.D. St. And., F.R.C.S. Eng.

BY the death of Dr. Alfred Bowyer Barton, which occurred on July 4th at Brechin-place, London, S.W., in his 80th year, the medical profession loses one of its oldest members and one whose career led him into different paths from those usually pursued by the ordinary practitioner. He was born at Bungay in 1825 and in 1844 entered University College, London, as a student, among his friends and contemporaries being the late Sir Richard Quain, the late Mr. Cadge of Norwich, and the late Dr. James Wakley. In 1847 he entered the West India Mail Steamship Service and worked through the yellow fever epidemic in the West Indies of 1848. He next entered the Peninsular and Oriental Company's service as medical officer and worked in the East till 1855, when he went to the Crimea, where he was mainly employed in moving the sick and wounded from Balaclava to Scutari. After the close of the war he went to India during the Mutiny and was wrecked together with Havelock who was then on his way to the front. Dr. Barton's next scene of service was the China war of 1860, after which he settled at Shanghai. In 1861, together with Captain Blakiston and Colonel Sarel, he explored the Yangtse-Kiang, then an almost unknown river above Hankow. The party reached Pingshan on the Tibet border but were forced to return by the rebels. For their work each of them received the gold medal of the Royal Geographical Society. Dr. Barton then returned to England and took the M.D. degree of the University of St. Andrews and the Fellowship of the Royal College of Surgeons of England (by examination) and retired from active practice. Dr. Barton was a singularly powerful man, both physically and mentally. Until within a week before his death he was quite hale and vigorous. He leaves a widow, one daughter, and three sons.

GEORGE FREDERICK WALES, M.D. ABERD., F.R.C.S. EDIN.

To the profound regret of all who knew him, Dr. Wales, who previously to his retirement had a very large practice in the north of Ireland, died on June 27th. He was the son of John Wales, the descendant of an Essex family which settled in Ireland in the eighteenth century, and he received his early education at the Royal School, Dungannon. He studied medicine at Aberdeen, Edinburgh, and Belfast, and graduated Bachelor of Medicine of the University of Aberdeen in 1857. Ten years later he took the degree of Doctor of Medicine of that University, and in 1877 obtained the Fellowship of the Royal College of Surgeons of Edinburgh. At one time he was president of the Ulster Medical Society and was the author of several monographs on medical subjects. The early part of his medical career was marked by an incident which at once stamped him as a man of unflinching courage and tact. The steamship *Philadelphia* of the Inman line, of which he was medical officer, was on her maiden voyage wrecked off Cape Race and the coolness and address with which he dealt with the 600 panic-stricken passengers aboard were such as to earn for him the special thanks of the company for his services on that occasion. As resident surgeon at Downpatrick Infirmary he did some admirable work at that institution and as a member of the Belfast town council he was a prominent advocate of sanitary reform. At his instigation some valuable practical work was carried out. He was one of the original shareholders in the White Star Line and was closely associated with the founders of the company. Dr. Wales in 1859 married Miss Charlotte Greer of Dungannon. Three of his sons are now medical men and one is a clergyman of the Church of England.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF PRESIDENT.

Mr. John Tweedy was re-elected on Thursday afternoon last, July 13th, President of the Royal College of Surgeons of England, Mr. H. T. Butlin and Mr. Edmund Owen being elected Vice-Presidents.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated :—

PART I.

Biology.—U. J. Bourke, London Hospital; and R. S. Minchin, St. Thomas's Hospital.

Chemistry.—H. S. Brown, University College, Nottingham; and R. J. W. McKane, Leeds.

Materia Medica and Pharmacy.—W. E. Dimond, Liverpool; E. R. Nezet, Edinburgh; P. D. Pickles, Leeds; and C. J. Wolfe, Edinburgh.

PART II.

Anatomy.—L. G. H. Furber, St. Bartholomew's Hospital; W. J. Gibson, London Hospital; T. Huddleston, Birmingham; C. J. M. Lawrence, Manchester; E. A. Mordaunt, Royal Free Hospital; G. F. Page, St. Bartholomew's Hospital; A. Perlman, Leeds; and P. A. Sullivan, Birmingham.

Physiology.—L. G. H. Furber, St. Bartholomew's Hospital; T. Huddleston, Birmingham; C. J. M. Lawrence, Manchester; P. J. Lush, London Hospital; E. A. Mordaunt, Royal Free Hospital; G. F. Page, St. Bartholomew's Hospital; and P. A. Sullivan, Birmingham.

UNIVERSITY OF BIRMINGHAM.—The following is a list of the successful candidates in the Faculty of Medicine :—

I. *Degrees of Bachelor of Medicine and Bachelor of Surgery.*—(a) Official: Frank Marsh. (b) Under Ordinary Regulations.—Edward Lancelot Bunting, Leonard Leigh Hadley, William Claude Horton, William Cuthbert Houghton, Henry Percy Pickerill, Thomas Holmes Ravenhill, Norman John Lancelot Rollason, and Frederick Wilkinson (scholarship).

II. *Fourth Examination* [illegible] *Ch.B.*—Class II.: Herbert Charles Horac[illegible] Lionel Chattock Hayes, Arthur Cecil Hi[illegible] [illegible]d Walter Rowland Southall Roberts.

III. *Third Examination for the Degrees of M.B., Ch.B.*—Class II.: Edward James Boome, Henry Neville Crowe, James Fenton (scholarship), Eric Thomas Gaunt, John Kennedy Gaunt, Philip James Mason, Nevill Coghill Penrose, Arthur John Smith, Rupert Wesley Thompson, and Francis Brett Young.

IV. *Second Examination for the Degrees of M.B., Ch.B.*—Class II.: John Adams, Charlotte Bailey, Mary Clarke (scholarship), George Henry Chavasse Mold, John Lichtenstein Ritchie, Herbert Henry Sampson, and Edward Vernon Whitby.

V. *First Examination for the Degrees of M.B., Ch.B.*—Class I.: Cranston Walker. Class II.: James Henry Bampton, Walter Charles Blackham, Norman Alexander Boswell, Charles William Hayward, Humphrey Francis Humphreys, Violet Maud McCready, Arthur Harry Newton, Kenneth Douglas Wilkinson, and Harry Wilks

VI. *Degree of Bachelor of Dental Surgery.*—Reginald Hudson Astbury.

VII. *Degree of Bachelor of Science in Public Health.*—(a) Official: Robert Arthur Lyster. (b) Under Ordinary Regulations.: Sidney Herbert Hawley and William Sisam.

TRINITY COLLEGE, DUBLIN.—At examinations held in Trinity term the following candidates were successful :—

FINAL EXAMINATION.

Section B.—Francis R. Coppinger, John D. Sands, Thomas H. Peyton, Richard A. Connell, John C. P. Beatty, Edward Gibbon, Gustav W. Thompson, Basil G. [illegible]son, Samuel G. S. Haughton, Thomas J[illegible] [illegible]hompson, Henry D. Drennan, Alfred C. [illegible] Ernest C. Phelan, Herbert J. Wright, Theodore C. [illegible] Dudley F. Torrens, Malcolm K. Acheson, Daniel M. Corbett, Thomas L. de Courcey, and Herbert R. R. Fowler.

PREVIOUS MEDICAL EXAMINATION.

Anatomy and Institutes of Medicine.—William S. Thacker, Johannes C. Pretorius, Wilfred J. Dunn, Frederick Stevenson, David J. Miller, Allman J. Powell, Charles H. O'Rorke, Edmond H. Sheehan, James C. C. Hogan, Henry de C. Dillon, Thomas P. Dowley, Denis J. Stokes, John A. L. Hahn, Albert V. J. Richardson, James Yourell, William Knapp, James D. K. Roche, Ernest N. Ryan, an William H. [illegible]

Physics and [illegible] Hughes, Arnold K. Henry Albert Stals [illegible] G. Leeman, William S. Boxwell, Cl[illegible], Peter H. Lemass, James Alston, Louis Trichard, William R. Watson, Charles H. Denham Hubert G. Holdbrook, Robert E. T. Tatlow, Adams A. M'Connell John C. Baker, Ernest Jameson, Frank Smartt, Alexander S. M Winder, Gervase Scroope, and Alfred H. Smith.

Botany and Zoology.—Arnold K. Henry, David L. M'Cullough Beatrice M. Hamilton, Thomas A. Hughes, Cecil P. Smyly Perceval G. Leeman, William P. H. Smiley, George Elliot, James H. Crane, William R. Watson, Edward P. Allman-Smith, Hilgard Muller, Adams A. M'Connell, Marius A. Diemont, John Gardiner Henry H. Ormsby, Euphon M. Maxwell, Eric J. Powell, John D Kernan, Victor G. Best, and William A. Taylor.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. T. Bergell has been recognised as *privat-docent* of Internal Medicine.—*Erlangen:* Dr. Lüthje o Tübingen has been appointed Extraordinary Professor o Preparatory Medicine and of the History of Medicine.—*Florence:* Dr. D. Crisafi has been recognised as *privat-docent* of Children's Diseases.—*Freiburg:* Dr. Emil Kuste has been recognised as *privat-docent* of Hygiene and Bacteriology.—*Königsberg:* Dr. T. Cohn has been recognised as *privat-docent* of Internal Medicine and Dr. R. Scheller as *privat-docent* of Hygiene.—*Odessa:* Dr. Golovin has been appointed to the chair of Ophthalmology.

A NEW WORKHOUSE INFIRMARY FOR PLYMOUTH—At the meeting of the Plymouth board of guardians held on July 7th it was decided to ask the Local Government Board to allow the guardians to proceed with the erection o the first section of a new infirmary which will cost about £10,000 and will provide accommodation for nearly 10 patients.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following prizes were awarded for the summer session, 1905:—Barker anatomical prize (£26 5*s.*), T. A. Burk; special prize (£21), J. B. Kelly. Carmichael scholarship (£15), R. M. Bronté. Gold and silver medals in operative surgery: gold, J. Prendiville; silver, R. Bury and L. Lucas (equal). Stoney memorial gold medal in anatomy, T. Sheehy. Practical histology: G. C. Sneyd, first prize (£2) and medal; and E. Harrison, second prize (£1) and certificate. Practical chemistry: Miss A. F. Nash, first prize (£2) and medal; and T. A. Peel, second prize (£1) and certificate. Public health and forensic medicine: C. J. B. Dunlop, first prize (£2) and medal; and W. E. M. Hitchins, second prize (£1) and certificate. Materia medica: C. J. B. Dunlop, first prize (£2) and medal; and V. J. Clifford, second prize (£1) and certificate. Biology: E. A. Gregg, first prize (£2) and medal; and E. Harrison, second prize (£1) and certificate. The next preliminary examination is fixed for Tuesday, Sept. 26th. The School of Surgery will resume work on Monday, Oct. 2nd.—Mr. Michael Ulick O'Sullivan, L.R.C.S. Edin., &c., having passed the necessary examination, has been admitted a Fellow of the College.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—Mr. H. T. Butlin distributed the prizes to the successful students at the London (Royal Free Hospital) School of Medicine for Women on June 29th. Afterwards Mr. Butlin delivered a short address to the students in which he remarked that not long ago it had been predicted that women had neither the courage nor the strength to enable them to pass through the medical curriculum but it was now, of course, well known that women were quite able to do this. It was also foretold that women would be unable to pass the necessary examinations but now everyone knew that they not only passed examinations but took the highest honours attainable. A few months ago the success of the women students in the chemistry examination of the University of London was absolutely exceptional. It had also been prophesied that if women did pass the necessary qualifying examination for practising medicine they would not have the nerve to carry on practice but that had been proved to be false by the fact that so many medical women were now carrying on extensive practices. On looking into the figures of the University of London there was found a slight and steady increase of the number of women in the medical faculty. Out of 16 women candidates who presented themselves for the degree of Doctor of Science 14 succeeded and such a high percentage a very extraordinary occurrence. Incidentally Mr. in observed that there was not one single Doctor of ic; in fact, only 12 women had presented themselves examination for the degree of Bachelor of Music and of e 12 only three had taken that honour.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Select Committee on the Registration of Nurses.

IE Select Committee of the House of Commons which has been ring evidence for and against the registration of nurses since last r has now commenced the consideration of its report.

A Fortunate Bill.

t this late period of the session it is next to impossible to make gress with a private Member's Bill, for the reasons that all the time t the disposal of the Government and that such a Bill can only ceed by consent after midnight. The Bill which General LAURIE introduced year after year to amend the Medical Act of 1886 has at last moment found itself in the fortunate position of being arded with a kindly eye in all quarters and the result is that it passed its second reading and committee stages in the House of mmons this week without a word of comment or discussion. As re is now every prospect that the Bill will become law this sion the memorandum printed with the Bill may be quoted:—n order to facilitate the admission of colonially trained and registered dical men to practise in Great Britain and hold appointments in the perial service, the Act of 1886 provided for reciprocity between the other country and such of the self-governing colonies as might mply with certain conditions, but that Act expressly stipulates that hen any colony had a provincial and a federal organisation such ciprocal arrangements should be entered into with the federal vernment and not the provincial. In the case of Canada the British orth America Act of 1867, enacted by the Imperial Parliament, pressly provides that education shall be entirely under the control of e provincial and not the federal governments, so that it is impossible bring the Act of 1886 into force with Canada. It is impracticable to mend the British North America Act of 1867 and to transfer the ontrol of education to the federal authorities, and therefore it is the bject of this Bill to amend the Medical Act of 1886, without in any ay interfering with the principle, and to enable reciprocal arrangements to be entered into either with the federal or provincial governments." General LAURIE has the support of Sir WALTER FOSTER, Sir JOHN BATTY TUKE, Mr. ROTHSCHILD, Sir HOWARD VINCENT, Mr. MIDDLEMORE, and Sir MANCHERJEE BHOWNAGGREE.

The Education of Afflicted Children in Ireland.

A new Government Bill has been introduced to make better provision for the elementary education of afflicted children in Ireland.

Bills Abandoned.

Many Bills promoted by private Members have been dropped. Amongst those sacrificed are the following: Compulsory Vaccination (Mr. BROADHURST); Juvenile Smoking (Dr. MACNAMARA); London Hospitals, Exemption from Rates (Mr. HAYES FISHER); Lunacy Acts Amendment, London (Sir JOHN BATTY TUKE); Milk Depôts, London (Mr. LOUGH); Nurses and Private Nursing Homes Registration (Mr. CLAUDE HAY); Nurses Registration (Mr. MUNRO-FERGUSON); Pharmacy (Mr. LOUGH); Public Health (Dr. C. F. HUTCHINSON); Sale of Whisky (Sir HERBERT MAXWELL); and Vaccination (Mr. STANHOPE).

HOUSE OF COMMONS.

WEDNESDAY, JULY 5TH.

Plague in Madras.

Sir WALTER FOSTER asked the Secretary of State for India whether there had recently been outbreaks of plague in Madras which had been traced to intending emigrants housed in the emigrant depôts, and, if so, whether any steps had been taken to remove the emigrant depôts to some suitable position outside the city in order to protect the residents in Madras.—Mr. BRODRICK answered: Two or three cases of plague occurred in villages near the emigration depôts but I am not aware that any case has been traced to the depots. The Madras Government may be relied on to take all needful precautions. The latest returns of plague show that during the week ending June 10th there was only one fatal case of plague in Madras city.

Measles in Belfast.

Mr. JOSEPH DEVLIN asked the Chief Secretary for Ireland whether his attention had been called to the fact that on June 22nd, 1905, a [illegible] Belfast Summons Court carrying a child [illegible] consequence of which her removal from [illegible] —her the Notification of Diseases Act was in force in Belfast, and, if so, who was responsible for the case referred to not being reported to the proper authorities; and whether any inquiry would be ordered in the matter.—Mr. LONG replied: The incident referred to has not been reported to the Local Government Board. The Infectious Diseases (Notification) Act, 1889, is in force in Belfast but the definition of an infectious disease does not include measles. The local sanitary authority is empowered by Section 7 to extend the definition so as to include measles or any other infectious disease but it has not availed itself of this power in regard to measles.

Horses for Food.

Mr. CREMER asked the Under Secretary of State for Foreign Affairs whether he was now in a position to state the result of the inquiries which, in August last year and in this year, he promised should be made concerning the number of old and slaughtered horses or horses unfit for work that were periodically exported from this country to Belgium, Holland, and Germany; whether he could say for what purpose their carcasses were used; and whether their flesh was made into condiments of various kinds, returned to this country, and sold as articles of food.—Earl PERCY replied: In the Netherlands horses imported for the purposes of slaughter must be slaughtered in public slaughterhouses at Amsterdam, Rotterdam, de Leyde, or Neineguen. It is guaranteed that only sound meat is offered for public consumption. As regards Belgium, large numbers of horses, chiefly those which have been used in coal mines, are imported from Grimsby, Goole, Hull, and other ports on the east coast of England to Antwerp. When intended for human consumption they must be slaughtered at the public slaughterhouse and sold by butchers who only deal in horseflesh. Horseflesh does not appear to be made into meat extract in Belgium, but sausages for local consumption are manufactured. No horseflesh, except a few living animals, is exported to the United Kingdom. As to Germany, no export of horseflesh to the United Kingdom takes place from Hamburg, nor, it is believed, from other German ports, such flesh having no sale there and being easily recognised, more especially as all horseflesh is indelibly stamped on inspection with the word "Pferd." The larger part of the horses imported from the United Kingdom appear to have been, not for slaughter, but for riding and driving. About 130,000 horses a year are slaughtered in Germany, and as regards Hamburg a certain number are consumed by human beings, some being used at the Zoological Gardens and private menageries. The price varies from 2*d.* to 6*d.* per pound, sausages from 4*d.* to 6*d.* per pound. The following are the statistics respecting the export of horses of small value in 1904:—Value under £5: Belgium, 2475; Holland, 2333; Germany, 38; and France, 12. Value over £5 and under £10: Belgium, 14,492; Holland, 3893; Germany, 107; and France, 28. As regards France, reports from Dunkirk, Calais, Havre, and Cherbourg show that no horses unfit for further work are imported from the United Kingdom at any ports in those consular districts.

The Sale of Ether in Ireland.

Mr. JOSEPH DEVLIN asked the Chief Secretary for Ireland whether his attention had been called to the abuses arising from the unrestricted sale of ether in the county of Derry and to the inadequacy of the restrictions on the sale of laudanum in Ireland generally; whether he was aware that the want of more stringent regulations in regard to the sale of these drugs had been responsible recently for a murder in Derry county and the cause of a suicide in the city of Belfast; and whether, in view of the facts, he would take steps to mitigate the possibility of further abuses in connexion with the sale of these drugs.—Mr. LONG answered: Both ether and laudanum are scheduled as poisons under the Act of 1870. There is some reason to believe that ether is improperly sold in certain districts and the police will endeavour to bring offenders to justice, but I have no information that the provisions of the law as regards laudanum are evaded. The case in Derry is pending for trial and I abstain from making any statement in respect to it; and in the Belfast case the coroner's jury found that death was due to an accidental overdose of chloroform.—Mr. T. W. RUSSELL asked whether the Chief Secretary was aware that in Derry ether was sold in half-pint bottles cheaper than whisky.—Mr. LONG replied: I do not know that but I will inquire.

THURSDAY, JULY 6TH.

Cancer in Ireland.

Mr. SAMUEL YOUNG asked the Chief Secretary for Ireland how many operations for cancer had taken place in workhouses in Ireland; and how many of them had terminated in death during the eight years ending March 31st, 1905.—Mr. LONG replied: The records of the Local Government Board do not afford information on this subject.

The Central Midwives Board and Irish Midwives.

Mr. CHARLES CRAIG asked the Chief Secretary for Ireland whether he was aware that the Central Midwives Board of England had refused to place upon the roll of certified midwives nurses trained at the Belfast Maternity Hospital previously to March 31st, 1905, while it had placed on this roll nurses trained under similar conditions and up to the same date at the Dublin Maternity Hospitals, at the Cork Maternity Hospital, and at the maternity hospital at Limerick; what were the grounds for the action of the Central Midwives Board in the matter; and whether he would take steps to have the nurses in question placed in the same position as other nurses of similar training.—Mr. LONG answered: The Central Midwives Board is constituted under the Midwives Act, 1902, and the rules of the Board are subject to the approval of the Privy Council for England. The Irish Government has no functions in this matter, but I have been furnished by the Lord President of the Council with a statement on the question which has been prepared by the Central Midwives Board. I gather from this statement that the purpose for which certain hospitals in Ireland were recognised, and the Belfast Maternity Hospital was not so recognised owing to its failure to apply in time, ceased to exist on April 1st, when the temporary provision (Section 2) of the Act relating to existing midwives expired.

A Question of Alleged Pollution of Water.

Mr. PIKE PEASE asked the President of the Local Government Board whether the medical officer of health had reported to the Dartford rural district council that the pumping station at Darenth, Kent, sucked the adjacent surface springs to such an extent that they ebbed and flowed according to the pumping; that this water must be liable to pollution but that the water company denied this; and when the inquiry into the liability of this source of supply to pollution asked for by 20 resident householders on March 22nd, 1904, would take place.—Mr. GERALD BALFOUR said: I understand that the medical officer of health has made a report to the effect referred to. When the undertaking of the water company passed to the Metropolitan Water

Board the Local Government Board called the attention of the Water Board to this matter. The Water Board has made a series of tests, which have just been concluded, and I am now awaiting a report as to the result.

Experiments on Animals.

Mr. FIELD asked the Home Secretary whether, in view of the fact that the total number of vivisection experiments in 1905 exceeded those of 1904 by 13,478 experiments, he would cause inquiry to be made into this matter with a view to the abolition of vivisection.—Mr. AKERS-DOUGLAS said: I must point out to the honourable Member that this increase is almost entirely accounted for by the additional inoculations, hypodermic injections, and feeding experiments that have taken place. The total increase in all other kinds of experiments was only 45. These inoculations, which numbered 30,346 out of the total of 32,562 experiments performed in the year, in no case involved a serious operation, and a very large proportion of them were performed on behalf of public or local authorities. Constant attention is given to the matter but I am not prepared to take action in the direction suggested.

The Treatment of the Sick and the Wounded during War.

Dr. MACNAMARA asked the Secretary of State for War whether he would have prepared and would lay on the table a memorandum showing how far the recommendations of the Royal Commission of 1900 on the care and the treatment of the sick and the wounded during the South African campaign had been, or would be, carried out.—Mr. ARNOLD-FORSTER answered: I shall be happy to furnish the returns asked for by the honourable Member.

MONDAY, JULY 10TH.

The Recovery of Fees.

Sir CHARLES WELBY asked the President of the Local Government Board whether he was aware that in the case of an isolation hospital having no resident medical officer it was customary for the local practitioners to attend their own patients; and whether, in the event of any such practitioner being a member of the local authority to which such hospital belonged, it was the practice of the Local Government Board to take any steps to prevent the recovery by him of the usual fees paid by the local authoritity in such case.—Mr. GERALD BALFOUR said: I believe that not infrequently patients in isolation hospitals are attended by their own medical men. I am not aware of any case in which the Local Government Board has taken steps to prevent the recovery of fees in such circumstances, but I think it right to draw attention to the provision in Section 12 of the Municipal Corporations Act, 1882, which disqualifies a person for being a councillor of a borough if he has directly or indirectly by himself, or his partner, any share or interest in any contract or employment with, by, or on behalf of the council. There is a similar provision in the Local Government Board Act, 1894, as regards members of urban or rural district councils.

Conscientious Objection to Vaccination in Scotland.

Sir JOHN LENG asked the Lord Advocate whether the prosecution in Dundee of 21 parents who conscientiously objected to the vaccination of their children had been ordered by the Local Government Board for Scotland; whether such prosecutions took place in England; and why so many prosecutions of this kind were being conducted in one Scottish city.—The LORD ADVOCATE said: The Local Government Board does not directly order the prosecution of vaccination defaulters but is required by the Vaccination Act to see that its provisions are duly carried out. The Board communicates when necessary with parish councils calling attention to the provisions of the Act and among the parish councils lately so communicated with the parish council of Dundee was written to in the early part of the year. In regard to the latter part of the honourable Member's question, I have no information in regard to English prosecutions. The number of prosecutions, of course, depends on the number of defaulters.

BOOKS, ETC., RECEIVED.

ABERDEEN UNIVERSITY PRESS, LIMITED.

The Royal Medical and Chirurgical Society of London. Centenary, 1805–1905. Written at the Request of the President and Council. By Norman Moore, M.D., F.R.C.P., Honorary Librarian, and Stephen Paget, F.R.C.S., Honorary Secretary. Price not stated.

Wakefield, West Riding Asylum.—Locum Tenens for six weeks. Terms £3 3s. per week, residence, board, &c.

Weston-super-Mare Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Stalybridge, in the county of Cheshire; and at Bracknell, in the county of Berks.

Births, Marriages, and Deaths.

BIRTHS.

Culmer.—On June 9th, at Nassau, Bahamas, the wife of J. J. Culmer, M.R.C.S., L.R.C.P., of a son.

Easterbrook.—On July 6th, at Arnprior, Gorebridge, Midlothian, the wife of Alex. M. Easterbrook, M.B., C.M., of a son.

Finch.—On July 9th, at Purston, Pontefract, the wife of W. Stanley Finch, M.R.C.S., of a daughter.

Hope.—On July 4th, at Grove-park, Liverpool, the wife of E. W. Hope, M.D., of a daughter.

MARRIAGES.

Bradley—Cadbury.—On July 6th, at the Friends' Meeting House, Birmingham, Neville Bradley, M.B., to Margaret, fourth daughter of the late Richard Cadbury, J.P.

Warren—Buchanan-Dunlop.—On July 6th, at Christ Church, Reading, Alfred Castle Warren, M.R.C.S., L.R.C.P., of 15, Campden Hill-square, Kensington, to Sabina (Ina), eldest daughter of Lieutenant-Colonel H. D. Buchanan-Dunlop, R.A. (retired), of Whitley Rise, Reading.

DEATH.

Cameron.—On July 5th, at Edinburgh, Robert W. D. Macmartin Cameron, M.D., D.Sc., late of Newton Stewart, N.B.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

POISONING BY FOOD AT ELY (LLANDAFF).

Dr. R. Prichard, medical officer of health of Llandaff and Dinas Powis rural district council, refers in his annual report to a mysterious case of poisoning. It appears that a number of persons partook of "faggots" and peas in the village of Ely, many of whom subsequently suffered acute, griping, abdominal pains, followed by vomiting and diarrhœa, and afterwards more or less prostration. The symptoms set in from three to ten hours after eating the food, except in the case of a girl aged 12 years, who had only two spoonfuls of peas and who had slight griping pains about 15 hours later. The food was purchased at a small shop on the Cowbridge-road. Some persons ate at the counter in the shop, others in their own homes. Ten persons, including some young children, ate "faggots" only; none of them suffered any ill effects. Ten others ate peas alone, while 17 others again partook of both "faggots" and peas; all of them suffered as above stated. The peas evidently contained the poisonous matter, as 27 individuals who took the peas either alone, with gravy, or with "faggots" were seriously indisposed after a few hours, while no one was affected who only ate "faggots." All recovered in the course of two or three days. The symptoms from which the patients suffered led Dr. Prichard to suspect possibly sulphate of copper, which is sometimes used in the greening of peas, but there was no trace of any metallic poison found in the samples of the "faggots," peas (cooked and uncooked), soda, &c., which were taken to, and analysed at, the Cardiff and County Public Health Laboratory.

THE COST OF LIVING IN WEST AFRICA.

To the Editors of THE LANCET.

SIRS,—In answer to Mr. St. George Queely's queries in regard to the cost of living in West Africa the following information in regard to the Gold Coast may be of use. I have not seen West Africa since 1901, but the modes of living will not have materially changed since then. As regards the distance of the goldfields from the coast this naturally varies with their position. I was ten days' march up-country, but some companies were located only a few miles away. Practically it amounts to this. Measure the distance of the camp from the Sekondi-Kumasi Railway. Allow one day for the railway journey and 15 miles a day for the hammock journey.

Provisions are all tinned. The native sheep and goats are too awful for words. Nowadays everything—bacon, flour, butter, even cigars—can be obtained tinned, but naturally the cost is somewhat great. £3 10*s.* is very moderate for a week's rations which should be ordered directly from England for choice. This does not include drinks, As to the kind of food requisite, I learnt by experience one or two things that perhaps you will allow me to mention here. 1. Get as large a variety as possible and put in plenty of tinned fruits. I never enjoyed tinned peaches till I swallowed a whole tin of them in the forest of Kujumakrum. 2. Do not forget a metal sparklet bottle and plenty of sparklet bullets. Limes are fairly plentiful in West Africa and a fizzy lime drink is a great boon out there. 3. Take a Berkefeld filter and use it always. The company I was on provided us with a carbon drip filter! We knocked the "filtering" apparatus out of it and used it to store boiled water. If your correspondent cares to communicate with me I should be delighted to give him any information that lies in my power.

I am, Sirs, yours faithfully,

July 8th, 1905. WEST AFRICAN.

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Will you be good enough to insert this in your paper? I am in want of a cheap motor-car, four-seated, so as to be able to combine pleasure with business and am told that the "Leader," at 225 guineas, is a good reliable car, and not unnecessarily complicated (as I shall not keep a chauffeur). Will any medical man having experience of this car be good enough to give me his opinion, especially as to hill-climbing, silence, and petrol consumption? I am, Sirs, yours faithfully,

July 11th, 1905. PLUG.

AN OLD MEDICAL ACCOUNT.

A CORRESPONDENT has sent us an old medical account which presents several points of interest. It gives details of all medicines supplied and the chief point which strikes the modern medical man is the enormous quantity of medicine which the patient received; whether he took it all is another matter. The account commences on Nov. 11th, 1825, and closes on Dec. 31st, 1826. No charge is openly made for attendance but the bill may well be said to afford an illustration of the gibe that an apothecary was a man who poured drugs of which he knew little into stomachs of which he knew less. The patient was apparently in fairly good health during the early months of the year but on March 1st he led off with a mixture 2*s.* 6*d.* and powders 2*s.* These lasted him about two days and he continued thus every two days until March 14th, when n active measures were undertaken. From this date to the end the year the unhappy patient received every day a draught draughts and pill, with the occasional addition of a blister. whole account, including dressings, &c., came to £105 12*s.*

A CASE OF ZONA OF THE FOREARM AND HAND.

To the Editors of THE LANCET.

SIRS,—With reference to the case published in THE LANCET July 8th by Mr. R. E. P. Squibbs, I saw a patient last week, a man, a 40 years, who had several small clusters of vesicles situated on posterior surface of the upper arm and forearm and also on the do surface of the first and second fingers, following the course of musculo-spiral and radial nerves. He complained of neuralgic pa which were most severe at night.

I am, Sirs, yours faithfully,

LAWRENCE F. HEMMANS, M.B., B.S. Durh., F.R.C.S. Edin

Lewisham, S.E., July 10th, 1905.

THE CULT OF THE ROSE.

WE have received a copy of the special Rose Number of the Garden Magazine, published by Messrs. W. H. Collingridge of Aldersga street, London, E.C. In addition to a coloured plate of the new sin rose Maharajah there are several illustrations of beautiful roses rose gardens and the letterpress will be found both interesting instructive to all who admire England's emblem.

THE HOLMAN LIBRARY AT EPSOM COLLEGE.

THE following subscriptions have been received since the list of Holman Testimonial Fund was closed: Mr. Hugh E. Vardon, £2 2 Miss Topham, £1 1*s.* The Holman Library at Epsom College, building which the fund has been devoted, is now completed will be opened on Founder's Day, July 29th. Subscribers wishi to be present are requested to apply to the Headmaster, Epso College, for tickets.

◆

C. J. H. is thanked for his communication. The newspaper paragra in question had already been brought to our attention.

COMMUNICATIONS not noticed in our present issue will receive attenti in our next.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-squa (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Fr (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.).

TUESDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), S Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), We minster (2 P.M.), West London (2.30 P.M.), University Colle (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Thro (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golde square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Centr London Throat and Ear (2 P.M.).

WEDNESDAY (19th).—St. Bartholomew's (1.30 P.M.), University Colle (2 P.M.), Royal Free (2 P.M.) Middlesex (1.30 P.M.), Charing Cro (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's Colle (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M. National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samarita (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Norther Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M. London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-squa (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopæd (3 P.M.).

THURSDAY (20th).—St. Bartholomew's (1.30 P.M.), St. Thoma (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), S George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlese (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.).

FRIDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt Northern Central (2.30 P.M.), West London (2.30 P.M.), London

Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.).

SATURDAY (22nd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (19th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos-street, Cavendish-square, W.).—5.30 P.M. Annual General Meeting. Election of Office Bearers and Report of the Council.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (17th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. R. J. Reece: Immunity.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. S. E. Dore: Clinique. (Skin.) 5.15 P.M. Mr. C. Nourse: Atrophic Rhinitis.

TUESDAY (18th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Bidwell: Plaster-of-Paris Splints.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Taylor: Clinique. (Medical.) 5.15 P.M. Dr. H. Campbell: Observations on Diet.

WEDNESDAY (19th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Dunn: Diseases of the Conjunctiva and their Treatment.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Pardoe: Clinique. (Surgical.) 5.15 P.M. Mr. A. Lane: Abdominal Surgery.

THURSDAY (20th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Practical Surgery.

HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Lecture:—Mr. Smart: The X Rays in the Diagnosis of Renal Calculus.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy-square, W.).—5 P.M. Lecture:—Dr. H. Scharlieb: Some Post-anæsthetic Complications. (Post-Graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M. Mr. W. E. Miles: Neoplasms of the Rectum and Anus.

FRIDAY (21st).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Bidwell: Plaster-of-Paris Splints.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—*South Wales Daily Echo, Cambridge Chronicle, Eastern Daily Press, Western Mail (Cardiff), Bolton Daily Chronicle, Westminster Gazette, Irish Times, Spectator, Essex Observer, Literary Digest (New York), Scientific American, Morning Post, Morning Leader, Daily Chronicle, Yorkshire Daily Observer, Liverpool Courier, Gardeners' Chronicle, Southern Press (Scotland), Globe, Daily News, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. A. H. Abernethy, Pensacola, U.S.A.; Mr. F. Alcan, Paris; Messrs. C. Ash and Sons, Lond.; Dr. Stanley B. Atkinson, Lond.; Dr. W. Lloyd Andriezen, Lond.; Dr. A. G. Auld, Lond.; Dr. T. D. Acland, Lond.; Æternum nefas; Dr. Henry Ashby, Manchester.

B.—Mr. C. Birchall, Liverpool; Mrs. George B. Behrens, Fallowfield; Messrs. Bates, Hendy, and Co., Reading; *Birmingham Daily Post*, Manager of; Messrs. Burgoyne, Burbidges, and Co., Lond.; Sir Lauder Brunton, Lond.; Mr. L. C. S. Broughton, Langley; Dr. G. F. Barham, Claybury; *The Baker and Confectioner*, Lond., Editor of; Mr. Douglas Bryan, Leicester; Dr. E. R. Bowen, Cardiff; Dr. J. H. Bryant, Lond.; Messrs. John Bale, Sons, and Danielsson, Lond.; Mr. J. E. S. Barnett, Kingston Hill; Mr. Arthur E. Barker, Lond.

C.—Dr. C. C. Cumston, Boston; City of London Hospital for Diseases of the Chest, Lond., Secretary of; Dr. R. H. Creighton, Ballyshannon; Conjoint; Chorlton Union, Clerk of; Cameron Hospital, West Hartlepool, House Surgeon of; Messrs. T. Christy and Co., Lond.; Mr. J. R. Collins, Cheltenham; Mr. E. Collins, Sawbridgeworth; Children's Hospital, Sheffield, Secretary of; Dr. William Collingridge, Lond.; Mr. F. W. Clarke, Chorlton-cum-Hardy; Mr. J. Chatham, Seaforth; Mr. Michael Cahill, St. Francisco.

D.—Dr. D. Douglas-Crawford, Liverpool; Major C. Donovan, I.M.S., Egmore, India; Paul E. Derrick Advertising Agency, Lond.; Mr. T. Domela, Murren; Mr. J. Q. Donald, Colinsburgh; Mr. Haden Dadson, Lond.; Dr. Robert Ayton Dunn, Hertford; Mr. A. B. Duprey, Trinidad; Dr. E. H. Douty, Diss.

E.—Mr. J. R. Evans, Narberth; Messrs. Eason and Son, Dublin; Epsom College, Council and Headmaster of; Enquirer; Dr. J. G. Emanuel, Birmingham.

F.—Mrs. Frances Furnivell, Lond.; Mrs. Fawssett, Lond.; Dr. E. Sargood Fry, Edinburgh.

G.—Dr. E. W. Goodall, Lond.; Dr. E. A. Gates, Lond.; Dr. J. G. Gordon-Munn, Norwich; Messrs. W. and A. Gilbey, Lond.; Mr. E. Gooch, Lond.; Guy's Hospital, Dean of.

H.—Mr. C. J. Hemmens, Lond.; Dr. Stanley Hodgson, Salford; Dr. W. E. Heilborn, Bradford; Professor R. T. Hewlett, Lond.; Mr. James R. Hatmaker, Paris; Mr. Holmes, Pontefract; Mr. P. C. G. Hayward, Stowmarket; Mr. J. Holland, Winsford; Dr. F. Hare, Lond.; Messrs. Haasenstein and Vogler, Geneva.

I.—Messrs. Irvine and Garbutt, Selly Oak; Incorporated Medical Practitioners' Association, Lond., General Secretary of; International Journal of Surgery Co., New York.

J.—Dr. P. Sidney Jones, Sydney; Mr. J. W. Johnson, Goole; Dr. W. J. Smith Jerome, Oxford.

K.—Mr. C. B. Keetley, Lond.; Miss J. Keeve, Westward Ho; Messrs. R. A. Knight and Co., Lond.

L.—Mr. E. Leach, Witheridge; Dr. T. D. Luke, Edinburgh; Le Touquet Sports Office, Lond.; Messrs. Louis and H. Loewenstein, Berlin; Right Hon. the Lord Mayor of London; Mr. C. Leedham-Green, Birmingham.

M.—Dr. F. Morris, Cape Town; Mr. S. K. Mukerji, Allahabad; Mrs. Isabella Mears, Mark Cross; Lieutenant F. Percival Mackie, I.M.S., Goona; Medical Supply Association, Lond.; Dr. J. C. McWalter, Dublin; Dr. Ronald Campbell Macfie, Capelulo; Dr. A. MacBride, Newport, co Mayo; Dr. Mendel, Paris; Messrs. Merryweather and Son, Lond.; Manchester Medical Agency, Secretary of; Messrs. Mappin and Webb, Lond.; Manchester Northern Hospital, Secretary of; Mr. E. W. Marshall, Manchester; Middlesex Open Air Sanatorium, Ealing, Hon. Secretary of; Medicus, Louth.

N.—Dr. C. R. Niven, Liverpool; Northumberland House, Lond., Medical Superintendent of; National Society for Employment of Epileptics, Lond., Secretary of; Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.

O.—Sir Lambert Ormsby, Dublin; Ochil Hills Sanatorium, Milnathort, Secretary of; Ophthalmological Society, Lond.; Messrs. Orridge and Co., Lond.

P.—Dr. R. Prichard, Cardiff; Mr. H. Pickering, Tamworth; Mr. Y. J. Pentland, Edinburgh; Dr. R. H. Pulipaka, Serampore, India; Mr. H. Palmer, Lond.; Mr. N. Philipson, Birtley; Dr. F. W. Pavy, Lond.; Pigment; Messrs. Peacock and Hadley, Lond.

R.—Dr. Wm. Russell, Edinburgh; Royal College of Surgeons in Ireland, Dublin, Registrar of; Mr. E. A. Rawlence, Salisbury; Royal Sea Bathing Hospital, Margate, House Surgeon of; Royal Institute of Public Health, Lond., Hon. Secretary of; Dr. A. F. Blagdon Richards, Swansea; Mr. J. Randall, Liverpool; Messrs. Robertson and Scott, Edinburgh; Dr. Arthur R. Reynolds, Chicago; Dr. E. Robinson, Frensham; Roneo, Ltd., Lond., Secretary of; Royal Waterloo Hospital, Lond., Secretary of.

S.—Mr. G. F. Sheppard, Lond.; Mr. William Sheen, Cardiff; Dr. T. H. C. Stevenson, Walthamstow; Mr. Elliot Stock, Lond.; Mr. W. Sidney Sweet, Lond.; Messrs. Schimmel and Co., Lond.; Smith's Advertising Agency, Lond.; Mr. A. M. Singer, Lond.; Mr. F. E. C. Singleton, Rostrevor; St. Peter's Hospital, Lond., Secretary of; Society for the Study of Inebriety, Lond.; Dr. J. A. Shaw-Mackenzie, Lond.; Professor Saundby, Birmingham; Street Noise Abatement Committee, Lond., Hon. Secretary of; Dr. W. Cecil Sharpe, Darley Dale; Society of Apothecaries of London, Secretary of; Dr. R. Atkinson Stoney, Dublin; Scholastic, Clerical, &c., Association, Lond.

T.—Mr. J. Lynn Thomas, Cardiff; Mr. G. G. Turner, Newcastle-on-Tyne; Trinity College, Dublin; Dr. John C. Thresh, Lond.; Dr. Edward H. Taylor, Dublin.

U.—*University of Chicago Press.*

W.—Mr. P. W. Williams, Clifton; Messrs. W. Wood and Co., New York; Weston-super-Mare Hospital, Clerk of; W. P. G.; Messrs. F. Williams and Co., Lond.; Mr. P. W. Walker, Birmingham; Dr. E. Williams, Corwen; Major W. W. Webb, I.M.S., Berkhamsted; Mr. Henry S. Wellcome, Lond.; Mr. Barrington H. Willoughby, Edinburgh; Mr. Alexander Wilson, Manchester; Messrs. H. Wilson and Son, Lond.

Y.—Professor A. H. Young, Manchester.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. A. Anderson, Wadsley; Aberystwyth Infirmary, Secretary of; A. H.; A. J. W.; Messrs. T. and M. Armstrong, Lond.; Automatic Disinfectant Delivery Machine Co., Lond.; Dr. E. Albertelli, Salsomaggiore, Italy.

B.—Dr. H. C. Bastian, Lond.; Dr. G. S. Blandy, St. Albans; Mr. E. H. Beaman, Offord; Messrs. T. B. Browne, Lond.; Mr. C. E. Brettingham, Ilchester; Birkenhead Borough Hospital, Treasurer of; Mr. W. A. Beet, Beaudesert, Queensland; Bethel Hospital, Norwich, Clerk of; Bishopstone House, Bedford, Medical Superintendent of; Bayer Co., Lond.; "Bond," Brill; Messrs. J. H. Booty and Son, Lond.

C.—Mr. F. H. Cooke, Birch; Caxton Publishing Co., Newcastle-on-Tyne; Dr. G. E. J. Crallan, Bournemouth; Messrs. T. Cook and Son, Bombay; Dr. A. G. Coullie, Margate; Mr. H. Compton, Brighton; Messrs. J. and A. Carter, Lond.; Cheltenham General Hospital, Secretary of; Clerical, Medical, &c., Assurance Society, Lond.; C. F. S. B.

D.—Mr. J. Dale, Warrington; Mr. T. Dixon, Lond.; Dr. D.; Mr. R. Davis, Lond.; Dalrymple House, Rickmansworth; Messrs. Dowie and Marshall, Lond.

E.—E. T. T.; E. C. T.

F.—Dr. A. M. Fraser, Portsmouth; Dr. A. W. Fuller, Lond.; F. L. S.; Mr. W. S. Finch, Pontefract; Flower House, Catford, Medical Superintendent of; Mr. R. H. Fuller, Surbiton.

G.—Dr. A. S. Gubb, Aix-les-Bains; Dr. J. H. Goodliffe, Lincoln; G. R. Y.; Gateshead Dispensary, Hon. Treasurer of; General Life Assurance Co., Lond., Secretary of; Mr. K. W. Goadby, Lond.; Dr. E. W. H. Groves, Kingswood.

H.—Mr. A. B. Hood, Aber-Bargoed; Dr. F. M. Harper, Mill of Hole; Messrs. Heal and Son, Lond.; Messrs. J. Haddon and Co., Lond.; Messrs. S. Hall and Son, Stalybridge; Mr. E. F. Harwood, Brugspruit, South Africa; Mr. J. J. Hicks, Lond.; H. E. D.; Mr. F. Hargreaves, Manchester; Dr. A. E. Horsfall, Huddersfield.

J.—Dr. W. D. Johns, Parkstone; J. P.; Messrs. D. Hill Jack and Son, Glasgow; J. T. L.; J. C. B.; Mr. Y. M. Jones-Humphreys, Cemmaes.

K.—Miss Keene, Sketty; "Killarney," Folkestone.

L.—Mr. D. L. Lindsay, Aldershot; L. F. S.; Locum, Chiswick; La Zyma Co., Clarens, Switzerland.

M.—Mr. W. Mettam, Darnall; Mr. P. E. McElligott, Sheffield; Dr. P. W. Macdonald, Herrison; Mr. E. C. Masser, Waschbank; Dr. G. Metcalfe, Skelmersdale; Mr. T. E. B. Meyler, Lond.; Dr. S. Messulam, Manchester; Mr. S. B. Mason, Pontypridd; Messrs. Millar, Son, and Co., Lond.; Messrs. Terry Marshall and Co., Lond.; M. S. M. D.; Dr. C. K. Millard, Leicester; Dr. W. McCall, Painswick; Mr. J. M. Mangan, Ennis; Medical Graduate's College, Lond., Secretary of; Marconi's Wireless Telegraph Co., Lond.

N.—National Provident Institute, Lond., Assistant Secretary of; Norfolk County Asylum, Thorpe, Clerk of.

P.—Mr. J. D. Power, Reading; Mr. F. J. Pearson, Owston Ferry.

R.—Mr. E. Roche, Lond.; R. J. E.; Dr. J. J. Robertson, Portpatrick; Mr. J. Reidy, Lond.

S.—Mr. D. Stewart, Glasgow; Surgeon, Manchester; S. L. B. W.; Miss M. Shearsby, Southsea; Dr. T. E. Sandall, Alford; Messrs. Smallpiece, Allen, and Co., Lond.; Mr. H. Lionel Smith, Wankie, South Africa; Silwood Lodge, Brighton, Superintendent of; Salford Corporation, Treasurer of; Dr. C. J. Smith, Pendleton, U.S.A.; Sunshine, Chislehurst.

T.—Dr. C. B. Taylor, Nottingham; T., Sudbury; T. M.; Mr. J. Thin, Edinburgh.

A Lecture

ON

HÆMOMANOMETRY IN MAN.

Being one of the Advanced Lectures in Physiology delivered at the University of London

By GEORGE OLIVER, M.D. LOND., F.R.C.P. LOND., &c.

GENTLEMEN,—During the past few years physiologists as well as clinicians have displayed much activity in devising methods of sphygmometric observation in man, which, in trustworthiness, may be regarded as approximating to the manometric procedure of the laboratory. And it may, indeed, be said that they have succeeded not only in attaining this most important end but in making the suggested methods easy of application and as free as possible from errors of technique; so that their employment does not necessitate the acquirement of that skill or personal quality which can only be derived from special training or from the possession of a certain aptitude in the observer.

It is needless to enlarge on the importance of the accurate observation of the blood pressure in man, especially in our inquiries into living pathology or (as preliminary or supplementary to the hæmometric record in animals) in building up our knowledge of therapeutics, or in applying that knowledge; for that will be obvious to all. But before dealing effectually with the practical aspects of hæmomanometry we find some problems of a purely elementary nature which await solution, for our knowledge of the physiology of blood pressure in normal man is still somewhat limited notwithstanding the good work which has been done towards its elucidation by such able investigators as Marey, Roy and Adami, Mosso, Leonard Hill, von Basch, Gärtner, Recklinghausen, Erlanger, Potain, Riva-Rocci, Gumprecht, Hensen, C. Martin, A. Martin, Stanton, Crile, O. E. Stephens, T. C. Janeway, Cook, Briggs, and others.

In physiology and medicine—founded as they are on experimental observation—advance depends mainly on the discovery of new methods. It was the introduction of the principle of the measurement of the arterial pressure by fluid compression applied to a limb which has made the study of hæmomanometry in man trustworthy and demonstrable to all observers. Almost simultaneously two experimenters (Leonard Hill and Riva-Rocci) conceived the idea of measuring blood pressure by compressing air in rubber bags encircling a limb—the effect of that compression on the arterial circulation being indicated either by the mercurial manometer (Riva-Rocci) or by an aneroid standardised by the manometer (Leonard Hill).[1] So far their procedures are identical; not so, however, their methods of reading the arterial pressure. Riva-Rocci, disregarding entirely the movements produced on the mercurial column by the arterial pulsation, takes as his indication of the arterial pressure the closure of the artery as shown by the cessation of pulsation in the radial artery; while Leonard Hill accepts the maximal oscillation of his indicator as denoting the mean arterial pressure. There have thus arisen two different modes of reading the arterial pressure founded on essentially the same procedure. The method of Riva-Rocci has been largely adopted by observers in the United States and on the Continent, while that of Leonard Hill has found most favour in this country. As the records furnished by these two modes of observation differ widely, some confusion may arise in comparing the results of clinical work on blood pressure, and as the advocates of either of these methods sometimes regard their data as more trustworthy and of greater clinical value than those of the other, it may be well to discuss anew the physiological and clinical significance of these two indications of the arterial pressure.

THE SYSTOLIC AND DIASTOLIC ARTERIAL PRESSURES.

It is generally admitted that the closure of the artery (*à la* Riva-Rocci) indicates the maximal arterial blood pressure—that moment of greatest arterial pressure produced by the ventricular systole. I think there can be no doubt as to this fact; and just lately P. Lockhart Mummery and W. Legge Symes have demonstrated in this laboratory that the Riva Rocci sphygmometer applied to the left thigh of a dog and a mercurial manometer connected with the right femoral artery afford readings which are practically identical.[2] Now, as this is so, it follows that the maximal oscillation of the indicator, though synchronous with the systole, does not indicate the maximal blood pressure, for when it is developed the artery is far from closed and, moreover, it appears at a much lower point on the scale than does the occluding pressure.

Experimenters are by no means agreed as to the precise interpretation of the maximal oscillation in relation to the diastolic arterial pressure—whether it denotes the mean or the minimal diastolic pressure. Leonard Hill believes that the maximal oscillation of the mercurial column occurs in the animal at or about the mean arterial pressure, and in this he is supported by C. Martin, who, however, does not regard this relation as constant in man.[3] Howell and Brush, on the other hand, have demonstrated that the maximal oscillation of the mercury in experiments on dogs takes place when the arterial pressure is lowest and they consider that the mean arterial pressure corresponds fairly well with the mathematical mean between the maximum and minimum pressures.[4] It has always seemed to me that the maximal oscillation is obtained when the pressure of the pad sufficing to balance the arterial pressure which exists just before the ventricular systole (therefore the minimum arterial pressure) produces almost an intermittent collapse of the artery between the pulsations and yet allows the free onward flow of blood.[5] This fact appears to me to be proved by the following procedure. Apply two bags to the limb, using two recorders; place one on the arm and the other on the forearm; develop the maximal oscillation, when the readings of both recorders will be the same.

Disregarding the question as to whether the maximal oscillation precisely signifies the mean or the minimal diastolic pressure, we may, I think, safely view these two methods of reading the arterial pressure as differentiating it into systolic and diastolic—the arterial pressures synchronous with the systole and diastole of the ventricle; and if we take the diastolic to represent the minimum pressure and the systolic the maximum, the mean arterial pressure should be, for all practical purposes, the mathematical mean between them—e.g., $\frac{\text{D. } 100}{\text{S. } 130}$ M. 115.

DESIDERATA IN A HÆMOMANOMETER FOR PHYSIOLOGICAL AND CLINICAL OBSERVATION.

The practical and comprehensive study of blood pressure in man requires the fulfilment of the following desiderata: (*a*) The instrument should afford accurate readings of both the arterial blood pressures (systolic and diastolic) and of the venous pressure. (*b*) It should be sufficiently sensitive and adaptable to furnish trustworthy records from the peripheral as well as from intermediate portions of the arterial system; for example, from the digital (including the ungual portion of the finger), the radial, brachial, &c (*c*) The indicator should be free from inertia and from errors due to momentum. Therefore the mercurial column should be avoided. (*d*) There should be no mechanical device such as springs, &c., to get out of order or to deteriorate. (*e*) The scale should be wide and easy to read and preferably horizontal rather than vertical. (*f*) The apparatus should be easy to manipulate and should not require any special training in technique; moreover, it should be portable and compact and possess a general adaptability to practical requirements.

A NEW FORM OF HÆMOMANOMETER.[6]

As a contribution towards the attainment of this ideal I will describe an apparatus of simple construction which I have lately employed in my inquiries. The instrument is graduated from the mercurial manometer and is fixed in a box in a horizontal position. It consists of a glass tube about 12 inches in length[7] (Fig. 1, *a*), receiving at one and (*b*) the rubber tube which leads to the rubber bag encircling the part from which it is desired to take the blood pressure and terminating in an air bulb (*c*) and tap (*d*). A short column (25 millimetres in length) of absolute alcohol, coloured by Merck's fett-farben Blau (*e*), is used as the indicator. I have found that a short mercurial indicator is not sufficiently sensitive to show the diastolic pressure from the finger, but, as a rule, suffices for that from the arm and forearm, and becomes much more responsive to pulsation when conjoined with a drop of absolute alcohol. Spirit or mercury (preferably with a trace of spirit) may therefore be used as the indicator.

---

[1] I believe the credit of devising this method belongs to Leonard Hill, though his results were published after those of Riva-Rocci.

[2] See Journal of Physiology, vol xxxii., May, 1905.

[4] Boston Medical and Surgical Journal, 1901, vol cxlv., p. 146.

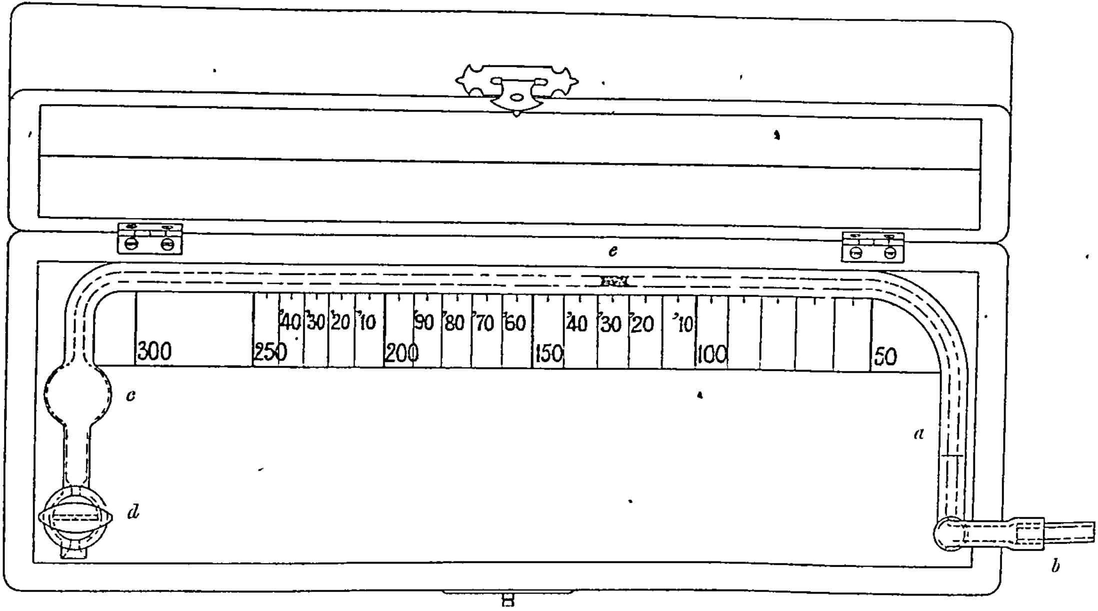
[5] See Pulse-Gauging, pp. 102, 103. 1895.

[6] This instrument was demonstrated at the meeting of the Physiological Society on June 17th, 1905.

[7] The length of the scale is determined by the capacity of the air bulb. For example, it may be extended to over 20 inches, the tube (fixed all round the inside of the box) being over 600 millimetres in length for 300 millimetres of mercury pressure.

The principle followed is to raise the air pressure in the rubber bag and to measure it by the compression of the air in front of the index. By this simple arrangement the air within the apparatus, when the tap is closed, becomes, as it were, a portion of the compressed air inside the bag and tubing—the degree to which the compression is carried by the observer being indicated by the upper end of the short column of the coloured spirit or mercury interposed between the two areas of compressed air. The principle of air compression for the measurement of blood pressure has been adopted by Hill and Barnard in their liquid sphygmometer and by Gärtner in his tonometer. The apparatus consists of (1) the hæmomanometer; (2) the filler and regulator, which are joined together so that the former may be squeezed by the hand and the latter may be actuated by the thumb, leaving the other hand free to feel the pulse during the reading of the pressures (diastolic and systolic); (3) rigid rubber connexions; (4) two air bags, canvas covered, with straps and friction buckles which are secure at any point, (*a*) 12 × 33 centimetres for arm and forearm and (*b*) 3 × 9 centimetres for phalanges and for the venous pressure; and (5) a stout rubber ring as compressor for taking the systolic digital pressure.

IG. 1.



The hæmomanometer.

ADVANTAGES.

This apparatus appears to me to present the following advantages over the mercurial manometer employed in clinical observation:—

1. Portability, compactness, and general adaptability to practical requirement without loss of accuracy.
2. The sensitiveness of the spirit indicator is shown by the fact that it enables the arterial pressure (diastolic) to be taken almost in the pre-capillary area of the arterial system (finger-tip) as well as in the arteries of the limbs.
3. This instrument furnishes the systolic and diastolic pressures in the finger (as afforded by Gärtner's tonometer and Mosso's sphygmomanometer) as well as in the limbs; and the venous pressure.
4. The scale being horizontal and open (instead of being vertical and contracted as in the U-shaped mercurial manometer) is read with ease and accuracy.
5. It possesses the advantage over a mercurial manometer of an absence of inertia which is practically complete. It may be a question as to whether the heavy column of the mercurial manometer, with an unequal pressure on each end of it (normal atmospheric pressure on the free end and increasing air pressure on the other), is open to errors due to momentum in the measurement of rising or falling pressures of a pulsating fluid, but no doubt can exist as to the trustworthiness of the principle of equal pressures on both sides of an index free from inertia, as in this manometer. "So heavy a liquid as mercury cannot possibly follow the rapid cardiac and respiratory variations in pressure, and it is to be emphasised that the extent of these on the manometric trace affords no measure of their actual value."[8] Hence the preference sometimes given in the laboratory to Fick's kymographion (a C-shaped spring being used instead of mercury), this instrument being more responsive to rapid variations of pressure than the mercurial manometer. In sensitiveness to such variations the spirit index of the hæmomanometer is superior to mercury and is equal to a spring.

The arrangement is likewise more simple and altogether more satisfactory than mechanically devised manometers, there being no springs or other mechanism to get out of order; though the long experience I have had with my hæmodynamometer does not lead me to depreciate mechanism.

POSSIBLE DEFECTS.

It may be urged that temperature and variable traces of spirit left on the bore of the glass tube between successive observations might be sources of error. (*a*) The question of temperature cannot well arise as the tap is opened and the index is adjusted to zero just before each observation. But might not warmth, conducted from the bag, expand the air on the proximal side of the index, especially when it remains *in situ* some time? This suspicion is, however, disproved by the mercurial indicator returning to zero after an observation. Then, again, if the air is heated by compression it will, of course, be so on both sides of the index and this will not be affected. (*b*) With the spirit index are the readings vitiated by varying traces of spirit left after observation? The average volume of spirit left on the bore has been ascertained approximately by measuring the index before and after observations—the loss in length having been converted into a volume loss by ascertaining how many millimetres of the tube bore represent a cubic centimetre.

---

[8] T. C. Janeway, M.D.: The Clinical Study of Blood Pressure, 1904, p. 5.

On comparing this loss in volume with the total air space to be compressed, it was found that this source of error amounts only to 0·45 per cent., which is negligible, especially as it is not easy to read smaller differences in arterial pressure than 2·5 millimetres of mercury. So far as I can ascertain, the more sensitive spirit index does not therefore introduce a practical or gaugeable error. Moreover, it has been found that after the first excursion of the index up and down the scale, subsequent ones do not reduce it, a certain average moistening of the bore preventing a further loss. It may therefore be well before making an observation, or a series of observations, to let the index slowly travel to 100 or 150 millimetres before fixing it at zero; and to drain from the bore any excess of spirit between repeated observations by tilting the box on its zero end for half a minute.

I have not yet quite decided on a standard instrument and the instrument maker has yet to settle details—as hitherto I have made my own instruments in different forms and have supplied several to friends for their criticism. It ought not to be costly to produce.

THE RELATIVE CLINICAL VALUE OF OBSERVATION MADE ON THE ARM AND FOREARM.

The arm, from its cylindrical form, even compressibility, and its single bone and artery, is anatomically well adapted to hæmomanometric observation, but these structural advantages are unfortunately counterbalanced by practical drawbacks. The procedure induces (*a*) a somewhat pronounced disturbance of the circulation of the limb (the venous outflow being arrested); and (*b*) considerable discomfort with its widespread effect on the vaso-motor system, raising the general arterial blood pressure from five to ten millimetres of mercury in proportion to the duration of compression and the sensitiveness of the subject. The latter disadvantage not infrequently engenders the practical difficulty of resentment on the part of the patient if at all sensitive or untrained to endurance of discomforts, and this objection to brachial hæmomanometry, though comparatively insignificant in male patients generally, is a substantial one with women, especially of the upper classes. Hence the practical importance of reducing the disadvantages of this easy mode of observing the arterial pressure without impairing its accuracy. With that object in view I have frequently made observations on the forearm, which are much less objected to than those on the arm, and readings so far have not differed in the two areas. The arm bag suffices for this purpose when evenly arranged in a somewhat spiral manner around the slightly tapering forearm, the radial artery being left exposed for the finger.

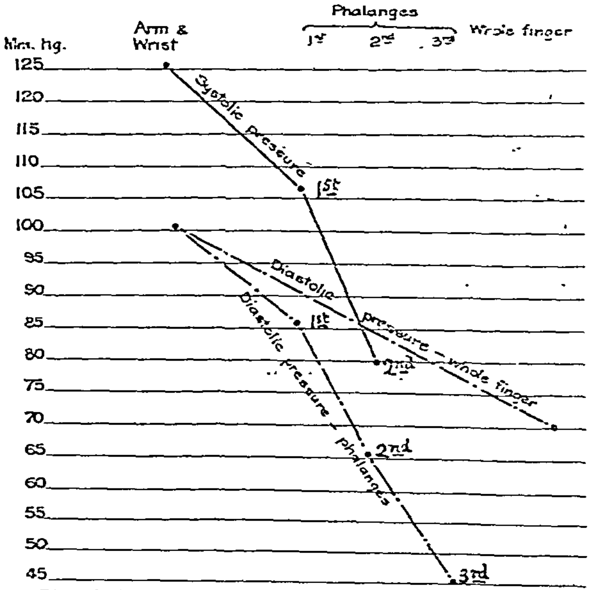
All the disadvantages just mentioned are not, however, encountered in observation on a single artery, such as the radial, ulnar, or temporal. And my experience and that of many others with the hæmodynamometer have shown that accurate readings of the diastolic pressure are furnished by this instrument, for they correspond with those of the mercurial manometer, so that observers who have acquired the necessary skill to use the hæmodynamometer may rely on its readings, and I am persuaded that their confidence in it will be strengthened by using the new manometer. Unfortunately the systolic pressure cannot be correctly furnished by any pressure gauge applied to a single artery. The new instrument, however, supplies this deficiency in the hæmodynamometer. Different structural conditions vitiate the reading of the pressure (systolic) required to close individual arteries whereas they do not interfere with the balancing of the diastolic pressure, the bore of the artery being free;[9] hence it is that the hæmodynamometer is trustworthy for determining the latter pressure only.

THE BLOOD PRESSURE IN DIFFERENT PARTS OF THE ARTERIAL SYSTEM (THE ARM, FOREARM, AND PHALANGES).

At the outset I should remark that the physiological data to which I am about to refer were derived in the first instance from my own circulation, which is normal, the digital portion of it being particularly well suited to demonstration of the distal blood pressure. After confirming them in others I have found that they furnish a trustworthy physiological standard for clinical observation.

As our knowledge of the blood pressure in the different districts of the arterial system in man is not so complete as one could wish, I will, as a contribution to it, adduce a few data showing the relation between the different pressures in the arm, forearm (upper and lower), *and finger (first, second, and third phalanges)*. But for the purpose of this comparison it is necessary to obtain the condition of physiological rest in the circulation—as complete rest as possible; for, as will be shown in the next section of this lecture, a state of circulatory activity, as after the ingestion of food or during and following exercise, disturbs the interrelation of the different pressures. I have found in every normal subject that there are periods during the waking hours, recurring with remarkable persistency, in which we may say that there is a fair degree of uniformity in the activities of the circulation, when the arterial pressure becomes practically constant. It undoubtedly varies within certain limits in different individuals and these limits are not so close as those of temperature, but for each individual it is fairly constant in the different areas. These periods recur, as a rule, quite regularly an hour before each meal when the body is in a state of rest. I have not found any appreciable difference between the arterial pressure (systolic and diastolic) taken from the arm and that taken from the forearm (upper and lower). If the pressure is actually less at the wrist than it is in the arm the reduction is not such as I can with certainty detect. In the arm the first decided drop in the pressure is found at the first phalanx; it is generally about 15 millimetres of mercury (100 millimetres of mercury diastolic in the brachio-radial area falling to 85). The reduction rapidly increases in the second and third phalanges, 50 millimetres of mercury being, as a rule, lost in the ungual part of the finger—the diastolic pressure there being roughly a little less than half that of the brachio-radial region (see Fig. 2). These facts show that the fall in blood pressure which takes place between arteries of intermediate size and the capillaries only becomes quite appreciable in the finer divisions of the arterial system, beyond which it is extremely rapid. It was observed that the systolic pressure diminishes more rapidly than the diastolic (see Fig. 2); in a word, the two pressures approximate more and more as the terminal arteries and arterioles are approached. The low reading obtained from the last phalanx suggests that in this area we are probably approaching the arterio ar or precapillary pressure. Pressure readings from this distal part of the circulation are not, however, always equally available—as, for example, when the fingers are cold, when the pressure falls much lower with feebler pulsations. Dr. A. Waller, applying his digital sphygmograph to the finger-nail, with an air-tight connexion with a mercurial manometer, obtained an approximate pressure of only 20 millimetres of mercury and found that the pulsation was abolished by cold.[10] Probably the higher pressure which I obtain from the last

FIG. 2.



Physiological constant of arterial pressure in brachio-radial (arm and wrist) and digital areas (1st, 2nd, and 3rd phalanges and the whole finger).

---

[9] See Pulse Gauging, 1895, and Blood and Blood Pressure, 1901.

[10] Brit. Med. Jour., vol. ii., 1900, p. 840.

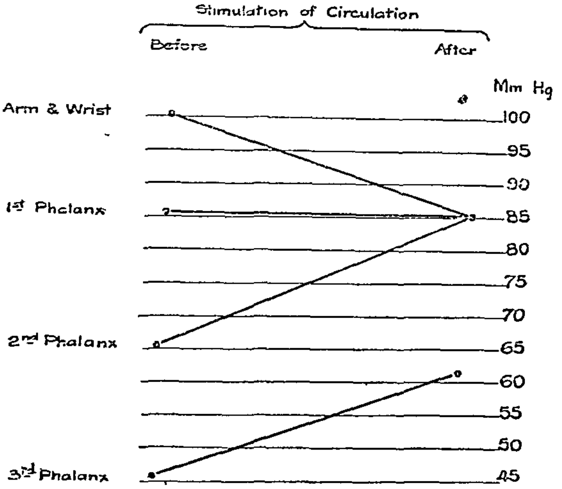
phalanx is due to the inclusion of terminal digital arteries by my finger-stall bag which are distributed outside the ungual area on which the pad of the sphygmograph rests.

THE PHYSIOLOGICAL VARIATIONS OF THE ARTERIAL PRESSURE.

I will first refer to the common features of the pressure variant due to stimulation of the circulatory mechanism, and then briefly to the variations in pressure caused by digestion, exercise, and temperature. According to my observation, when the circulation is thus stimulated, the normal relation which subsists between the intermediate and distal pressures is always altered.

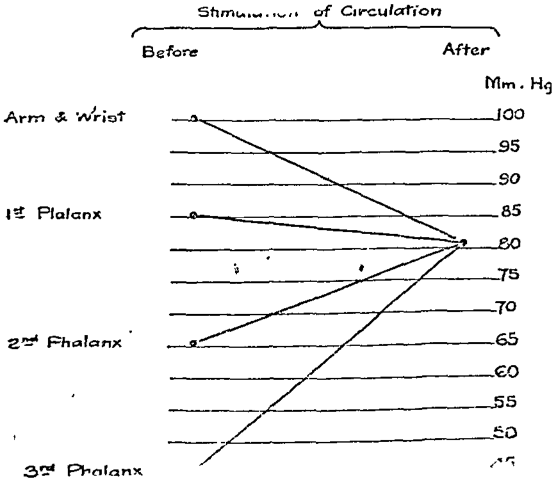
In all cases, except when cold lowers the peripheral pressure, considerable rise of the diastolic pressure takes place in the most distal area—the last phalanx; the pressure of 45 millimetres of mercury becoming, for example, 60, or 65, or even 70 millimetres of mercury or more, the increment varying from 20 to 60 per cent. (Figs. 3, 4, and 5). It has been found that when the distal rise exceeds 30 per cent. the diastolic pressure in the brachio-radial area generally falls and then the pressure tends to be, and it may actually become, uniform from the arm to the finger-tip (Fig. 4). It has frequently been found to be 80 or 85 millimetres of mercury throughout, as after exercise, exposure to heat, and under the influence of vaso-dilators—e.g., nitro-glycerine, the aromatic bodies, &c. A distal rise of 30 per cent. or less may, however, concur with a brachio-radial fall, but when it does not the diastolic pressure of the arm and fore-arm invariably rises and never remains stationary, as after taking small doses of vaso-contractors (Fig. 5). The invariable effect, then, of all these physiological stimuli on the arterial pressure is to produce a large relative rise in the peripheral area of the arterial system, whether the pressure in the intermediate arteries rises moderately or falls.

FIG. 3.



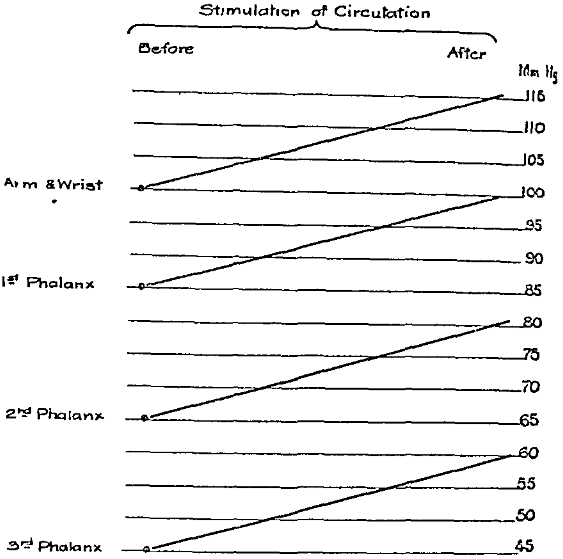
Physiological variant of the arterial pressure (diastolic) in brachio-radial (arm and wrist) and digital (1st, 2nd, and 3rd phalanges) areas when moderate vaso-dilatation takes place.

FIG. 4.



Physiological variant of the arterial pressure (diastolic) in brachio-radial (arm and wrist) and digital (1st, 2nd, and 3rd phalanges) areas when complete dilation takes place.

FIG. 5.



Physiological variant of the arterial pressure (diastolic) in brachio-radial (arm and wrist) and digital (1st, 2nd, and 3rd phalanges) areas when moderate vaso-contraction takes place.

It is quite conceivable how this event in the distal vessels is brought about when the blood pressure falls in the intermediate arteries, for vaso-dilatation will cause the pressure to rise in the peripheral arteries, arterioles, capillaries, and veins. This increment of distal pressure will be all the more pronounced and sustained should the maximum arterial pressure, due to the ventricular contraction, be maintained or, though falling, should be relatively higher than the diastolic pressure. But when the pressure in the peripheral vessels participates in a general rise of arterial blood pressure some factor besides vaso-motor action must come into play, for contraction alone lowers the pressure in the distal vessels. Observation points to cardiac stimulation as that factor, for I have always observed that when the diastolic pressure rises throughout the arterial system (in the digital as well as in the brachio radial area) the systolic pressure rises still more. It is therefore obvious that the lowering effect of physiological vaso-contraction on the distal blood pressure is more than compensated for by augmented ventricular contraction. Is the cardiac stimulation a reflex originating in the vaso-motor system? The two types of normal peripheral increment of blood pressure—viz., from (1) vaso-dilatation only and (2) vaso-contraction *plus* cardiac stimulation—have been followed by the arteriometer which has afforded evidence of radial dilatation in the former case and contraction in the latter.

The ingestion of food.—In the Oliver-Sharpey lectures delivered last year[11] it was shown that the ingestion of food induces a prolonged wave-like rise in the arterial pressure. These recent studies of the circulation have widened this first conception of the effects of meals on the arterial pressure; they have shown that the diastolic arterial pressure in the intermediary arteries (brachio-radial), though generally rising, frequently falls during digestion. But whether it rises or falls the peripheral arterial and the venous pressure show that the capillary pressure invariably rises. When the diastolic arterial pressure falls the systolic may likewise fall, or it may remain unchanged, or it may slightly rise; but when the diastolic pressure rises the systolic invariably rises also and to a higher degree. This varying ratio between the two pressures apparently depends on the vaso-motor tone and reflex ventricular response of the individual. When both arterial pressures rise together it has generally been observed, after the digestive stimulation of the ventricle is over, that the systolic pressure falls somewhat below that observed before the meal, as if this were a reaction fall (a depressor following the pressor effect), which is also generally observed after exercise or other forms of cardiac stimulation. Probably these data throw some light on the discrepancy of results obtained by different physiologists as to the effects of digestion on the arterial pressure.

---

[11] THE LANCET, April 30th (p. 1175) and May 7th (p. 1262), 1904.

Exercise.—During moderate exercise both arterial pressures (systolic and diastolic) rise; but on continuing the exercise the systolic maintains its higher level longer than the diastolic, though they both eventually fall—the diastolic being the first to subside below normal. Exercise (even muscular tension for short periods)[12] invariably produces a hypotonic effect on the peripheral vessels, lowering the diastolic pressure in the intermediate and raising it in the distal arteries, the capillaries, and the veins (Fig. 4); and this effect is still more pronounced when the circulatory muscular fibres (centric and peripheral) are reduced in tone.[13]

Temperature.—Warmth (whether local or general) approximates the phalangeal and brachio-radial pressures, while cold produces the contrary effect.

The comparative readings of the digital and brachial pressures should be useful in pharmacological observation (experimental and therapeutical) in man, enabling us to follow the effects of vaso-dilators and vaso-contractors, and should prove to be instructive clinically. They may enable us to directly determine peripheral resistance; as when high and due to vaso-contraction beyond the physiological limit and when low and due to vaso-dilatation—the pressure in the distal phalanx, and in the middle phalanx also, reading absolutely or relatively low in the former case and absolutely high in the latter. For example, a diastolic brachial pressure of above 130 millimetres of mercury is frequently associated with a distal digital pressure of from 15 to 35 (instead of 45) and a brachial pressure of 85 may coexist with a terminal pressure of 60, 65, or 70. When vaso-contraction persists within the upper physiological limit the digital pressures remain continuously higher than normal (above 45) and the tissue lymph lodges or has but a limited variation, as in many cases of chronic goutiness. But when the contraction exceeds that limit the distal digital pressure falls below 45, and tissue lymph fails to be exuded. Digital observation of the arterial pressure alone has not, so far as I can ascertain, proved of much clinical value but when conjoined with the determination of the pressure in the intermediate arteries it should be a useful auxiliary procedure in clinical hæmomanometry.

THE RELATION BETWEEN THE CAPILLARY BLOOD PRESSURE AND THE TISSUE LYMPH CIRCULATION.

Last year I endeavoured to show that there is a demonstrable relation in man between the capillary blood pressure and the exudation and absorption of tissue lymph. The rise and fall of the capillary blood pressure were, however, a matter of inference—a probable inference, it is true—from the simultaneous fluctuations of the venous pressure. Now the data furnished by these observations appear to me to strengthen that inference; for they demonstrate that the blood pressure on the immediate proximal side of the capillaries is raised, as well as that on their distal side, whenever tissue fluid is exuded and that the pressure falls on both sides of them when that fluid ceases to be exuded or is absorbed. In a word, the evidence shows that the streamlets which feed as well as those which drain the capillary lake rise and fall together.

THE NORMAL ARTERIAL PRESSURE.

What is the normal arterial blood pressure in the average healthy subject? Observing all the elementary precautions to secure uniformity of observation—such as selecting the same area of the circulation (e.g., the brachio-radial), the proper time of day (if possible an hour or so before meals), the same posture (avoiding a lateral one), and the gravity position of heart level—it will be found that the normal arterial pressure in adults is less variable than is usually believed, a diastolic pressure of from 95 to 100 or perhaps 105 and a systolic pressure of from 105 to 130 millimetres of mercury being the figures commonly met with. A good average normal reading in a young or middle-aged adult may be taken as $\frac{\text{95–100 diastolic}}{\text{115–20 systolic}}$, individual variations being included in the range just indicated. When, however, the causes of physiological disturbance are disregarded a wider margin must be given for the normal variant—e.g., $\frac{\text{80–120 diastolic}}{\text{90–150 systolic}}$. In women the pressures are generally about 10 per cent. less than in men; in children they are as a rule near the lower, and in the elderly near the upper, normal limit.

Probably the slightly higher reading—especially of the systolic pressure—in subjects over 50 or 55 is due to advancing diminution of elasticity of the large arteries (the circulatory work being thrown more and more on to the ventricle) as well as to increased peripheral resistance. The arterial pressure does not necessarily rise with age; I have, for example, frequently met with very moderate readings in normal subjects of 75, 80, 85, and 90. When the arterial pressure touches the upper normal limit or rises above it, it responds more decidedly to physiological stimulation (e.g., from digestion, exercise, &c.) than when the pressure is lower. Hence the pressure is, as a rule, more variable in the elderly than in the young. A persistent systolic pressure of over 145 millimetres taken within an hour before a meal should be looked upon as suspicious and requiring watching, especially when the diastolic pressure is raised from 10 to 20 millimetres. In subjects of over 50 or 55 years of age such pressures should not be passed by in a routine way as normal. If possible, they should be reduced by treatment, as they are apt slowly to increase in a latent way, year by year, and then may suddenly declare themselves in cerebral hæmorrhage or may terminate in cardiac failure (dilatation, &c.).

On the other hand, it is important to distinguish between unusually low normal pressures and pressures reduced by failure in vaso-motor tone, producing splanchnic stasis. For some years I have found the effect on the arterial pressure of abdominal compression (either by the hand or by a weight, e.g., a bag containing 14 pounds of shot) useful in deciding between these two causes of low blood pressure; for in subjects of normal vaso-motor tone the abdominal compression does not raise the arterial pressure, whereas when the tone is reduced it raises it to the normal level, or even above that level. The modifying influence of temperature (the hypotonic effect of heat and the hypertonic effect of cold) on the blood pressure should be kept in mind. According to my observation, warm weather may let down the brachial pressure (systolic and diastolic) from 10 to even 20 millimetres and raise the phalangeal pressures to a corresponding degree, and cold weather may raise the former and lower the latter to a similar extent.

Before an observer can be fairly well assured as to whether the arterial pressure is raised or not, he should ascertain whether the alteration in pressure is persistent or only temporary, and should sedulously exclude nervous excitement in the subject. The latter precaution is of prime importance; on account of it nothing in medical practice requires more tact and circumspection than the reading of the arterial pressure. I suspect that some of the high readings recorded are due to temporary rises due to nervous stimulation of the heart and vaso-motor system; and it has interested me to observe how often I have proved that the arterial pressure may be impressed by the state of the nerves when neither I nor the patient suspected that influence. High readings—e.g., from 160 to 180 diastolic and 250 systolic—should be accepted with some hesitancy; and the observer should always remember that when the peripheral resistance is increased the influence of nervous excitement, however slight, becomes much more pronounced than when the peripheral outflow is normal or subnormal.

THE PHYSIOLOGICAL RELATION BETWEEN THE SYSTOLIC AND DIASTOLIC PRESSURES.

At the pressure-constant periods I have found that the difference between the pressures varies in different individuals from 10 to 15, 20, 25, 30, 35, or 40 millimetres (the average being about 25 millimetres), the smaller differences being present in subjects below middle age and especially in children and in women, and the larger after middle age and especially in elderly subjects (over 60 years). The difference is remarkably uniform in the same individual but it is much less so during pressure-variable periods. As a rule, with vaso-contraction the difference widens, and with vaso-dilatation, while the two pressures usually fall together, they tend to approximate somewhat. A certain independency is not infrequently manifested, however, in the behaviour of the systolic pressure.

---

[12] Just lately M. C. Oddo (using Potain's sphygmomanometer) discovered a marked fall in the systolic arterial pressure after slight effort in convalescents, which he terms the "hypotension of effort." (THE LANCET, July 8th, 1905, p. 93.)

[13] Ibid.

THE RELATIVE CLINICAL VALUE OF THE SYSTOLIC AND DIASTOLIC PRESSURES.

The systolic pressure denotes the force of ventricular contraction and the diastolic pressure is one of our best guides in regard to the peripheral outflow—its freedom or otherwise. Therefore the specific indication of one pressure (systolic) is centric and that of the other is distal. Just now, it seems to me, there is a disposition to exalt somewhat unduly the clinical importance of the systolic pressure and proportionately to depreciate that of the diastolic, and sometimes the teaching would have us to disregard entirely the reading of the latter. Doubtless the comparative ease with which the systolic pressure can be read and the supposed greater uniformity of it have largely contributed to this attitude, which has been further prompted by the recent employment of this facile method of gauging the blood pressure while the patient is submitted to surgical procedures under anæsthetics.[14] But in medicine we cannot surely afford to discard the reading of the diastolic pressure, for the variations in peripheral resistance are of as great significance to the physician as are those of the cardiac centre. Long and well-attested experience teaches us that the reading of the diastolic pressure affords us valuable aid in judging of the state of the vaso-motor system and of the peripheral vessels and in suggesting lines of treatment. Moreover, that experience likewise teaches us that the persistent raising of the diastolic pressure increases enormously *the continuous strain on the arterial wall and the heart*, by reducing more and more their normal diastolic rest; thus favouring the development of all the consequents of that strain. A high systolic pressure is surely robbed of much of its power to injure the arterial wall when the diastolic pressure is low, as in aortic regurgitation, and when the peripheral circulation is open and free, as during exercise. Hence the trite remark of Sir Samuel Wilks: "I was quite of opinion that apoplexy or cerebral hæmorrhage occurred more frequently when the patient was quiet at home rather than when out of doors, employed at his avocation. ...... When we consider the number of persons engaged in their ordinary avocations who are the subjects of various diseases of the heart, of aneurysm, and decay of the blood vessels, ever threatening rupture, we might imagine they were exposing themselves to the dangers which would lead to the final catastrophe; but this is not the case, for it is generally when they are quiet at home that these events mostly happen."[15] We are too apt to forget that in muscular action the strain on the arterial system is relieved by the rapid transfer of blood through the open periphery of the circulation which it induces and that it thus provides a safe and natural outlet of the arterial pressure when unduly raised. Therefore it seems to me that in medical cases both readings of the arterial pressure, diastolic as well as systolic, are of at least equal importance and should be taken together.

THE CONTROL OF BLOOD PRESSURE BY PHYSIOLOGICAL PROCEDURES AND PRODUCTS.

One of the least encouraging aspects of the study of hæmomanometry is our limited power of controlling blood pressure by ordinary remedies. Vaso-tonics are useful enough as adjuncts to the more important means of improving the general health and the vaso-motor and muscle tone. But our depressor remedies, such as potassium iodide, salicylates, nitro-glycerine, &c., are somewhat disappointing when continued for some time. It is true they are often most useful in tiding our patients over threatening periods of intermittent increments of arterial pressure or in securing for a time some degree of diastolic rest to the heart and arteries when the pressure is persistently high, but their effect is temporary and they cannot well be persisted in for lengthened periods without impairing the health. Hence it is that during the last few years the profession has turned to physiology for aid in controlling the blood pressure more effectually and more enduringly than can be secured by drugs. We are practising the movement cures and allied physiological methods for modulating the blood pressure. And the results have not been disappointing. It is well known that muscular movement (whether active or passive) signifies transference of blood to the muscles and that the blood-vessels richly distributed through the muscles are capable of holding a large portion of the blood of the body. From these two facts it is easy to conceive how considerable is the power which the muscles possess over the arterial blood pressure. I just now pointed out to you that the various physiological stimuli (and among them muscular action is the most powerful) call into play a mechanism by which blood is transferred from the more central to the peripheral parts of the circulation—in a word, from the apex to the base of the triangle, which figures to us the bed of the circulation. This is the physiological explanation of all our movement cures. All these therapeutic methods (massage, regulated and resisted exercises, tension exercises, electric excitation of muscles, passive movements, &c.), with or without the valuable adjunct of temperature in the form of bathing, go far beyond any drugs in restoring the beautiful mechanism by which in all healthy subjects blood is rhythmically flushed through the periphery of the circulation where all the metabolic commerce of the body is transacted, the arteries and veins being mere conduits. But may we not go further than this? Some observations (physiological and clinical) during the past two years have encouraged me to hope that the continuous administration of certain physiological products may afford more effectual control over the arterial blood pressure than by other means. Among the moderators of that pressure the members of the benzoic or aromatic series (such as hippurates, benzoates, cinnamates, coumarates, &c., and their derivates) have more particularly interested me. The blood pressure (diastolic and systolic) in the intermediate and large arteries and in the ventricle is raised so long as the base of the arterial triangle is narrowed and can only be lowered by enlarging that base. Hence it is that vaso-dilators first let down the diastolic pressure and then the systolic. My observations lead me to believe that in the aromatic group of bodies will be found some persistent vaso-dilators which may be taken for lengthened periods without impairment of their dilating property and without harm to the body—that class of remedy which the physician regards as ideal for the effectual control of hypertension of the peripheral arteries. The allied oxybenzoic series, to which salicylic acid belongs, also contains members which should be investigated from the blood pressure point of view. My experiments in this laboratory are in progress and I trust later to have obtained sufficiently corroborative evidence from animals in support of my observations on man.

The aromatic bodies are widely distributed throughout the vegetable kingdom; and we know that a vegetarian diet favours the lowering of the arterial pressure. It is just possible that this effect of vegetables—especially green vegetables—largely depends on the presence of these substances; if so, may it not be possible to secure the advantages of a vegetarian diet on the circulation by prescribing small doses of members of the aromatic series, while a more generous supply of nourishment may be permitted than can be obtained from vegetables only? This study of the blood pressure in man suggests that clinical hæmomanometry should be perused on more comprehensive lines than hitherto; for it is obvious that when all the available pressures (intermediate and distal, arterial and venous) are taken the data obtained are more likely to be consistent and trustworthy than when observation is made on one particular area—e.g., brachial or digital.

[Dr. Oliver demonstrated the use of the hæmomanometer at the close of the lecture. He showed how the instrument should be used as a companion to the finger in gauging the pulse and the blood pressure, the arterial pressure (diastolic and systolic) being taken from the arm, forearm, thigh, leg, and the phalanges (first, second, and third) and the venous pressure from the hand, &c., at the same time pointing out the various precautions to be observed. He also indicated a simple and time-saving method by which the diastolic pressure may be correctly taken by the instrument without circular compression of the limb. These and other practical details will appear in the reprint of this lecture.]

---

[14] Mr. J. P. L. Mummery's recent Hunterian Lectures (THE LANCET, March 18th (p. 695) and 25th (p. 776), and April 1st (p. 846), 1905) show how valuable manometric observation of the blood pressure may be in surgical work.

The Wightman Lecture

ON

SOME OF THE NEUROSES OF EARLY LIFE.

Delivered before the Society for the Study of Disease in Children on May 19th, 1905,

BY HENRY ASHBY, M.D. LOND., F.R.C.P. LOND.,
LECTURER ON DISEASES OF CHILDREN, VICTORIA UNIVERSITY, MANCHESTER.

MR. PRESIDENT AND GENTLEMEN,—In these days of lectures and addresses, to say nothing of the intense activity displayed in all departments of medicine, it is not easy for a lecturer to find an untrodden path or feel that he can add anything to the common stock of knowledge. I must crave your indulgence if—in delivering the address which your council in its goodness has imposed on me—I traverse some rather open and well-known ground.

Important contributions to our knowledge of the neuroses of early life have been made in this country by such well-known observers as Gee, Warner, Shuttleworth, John Thomson, Still, and many others; while in the allied domain of social psychology the names of Romanes, Sully, and Mark Baldwin will at once suggest themselves. To all these writers I must express my deep indebtedness. It is not easy to define the limits of a neurosis; but the task which I have set before myself to-day is to speak of the functional disorders due to a failure of coördination or a backward development of the lower nerve centres and of the minor mental abnormalities occurring during early life due to a lack of inhibition or a morbid sensitiveness of the higher level centres. It need hardly be said that I am not attempting to cover the whole ground occupied by the neuroses and psychoses of early life, for to sum up all the moods and tempers of the twentieth-century child would require a volume. I must be content to pass in review only a few and perhaps be deemed guilty of omitting some of the most important.

There is some difficulty attending the use of the term "functional disorder"; what one may call a "functional disorder" or "neurosis," another with good cause may say "what you call a 'neurosis' is only an exaggeration of what is seen in every child when over-excited, or tired, or in ill-health." Or, on the other hand, a neurosis such as eclampsia may be due to some organic change in the nerve cells or some focal lesion. I must risk such criticism, bearing in mind that there are no hard lines in the classification of disease and great comfort in taking refuge in the word "borderland."

Since Darwin, "variation" has been looked upon as one of the broadest facts of biology; differences of disposition, temperament, and character are met with in members of every family. It is, however, I think, a matter of common experience that neurotic parents have neurotic children. Heredity does not necessarily show itself in fully developed disease at birth or in every member of a family; an imbecile woman does not necessarily bring forth an acephalic fœtus or an epileptic or insane father an imbecile. There is, however, a strong probability that if a family results from the union of neurotics or degenerates some members of that family will show a tendency to unstable nerve centres or mental feebleness. There is no strain through the generations so strong and persistent as the tendency to unstable nerves and mental degeneration. In nature the weakly and unstable are weeded out before they have the chance of breeding. In our highly organised and philanthropic civilisation the weaklings and neurotics are tided over their infancy by thousands and preserved till manhood. Social conditions rather than natural laws regulate the union of the sexes.

Are we more neurotic than our forefathers who followed the tail of the plough and lived upon the produce of their land? Have not the unrest and excitement of these later days told not only upon men and women but also on their offspring? In our large cities we are beginning to discover a large accumulation of "by-products" or "*Nebenconsequenzen*" in the shape of the criminal, the pauper, the epileptic, the imbecile, and the insane, with the prospect at no distant date, as several writers have pointed out, of one half of the population having to nurse, to cherish, and to support the other half. The individual born to-day repeats the gains of former generations, the individual gains becoming race gains; but is it not equally true that in the long run individual degeneration becomes race degeneration? The fertilised ovum has implanted on it not only the characteristics of races, families, and individuals, but it has been modified by climate, nutrition, education, and toxins. It is "the heir of all the ages in the foremost files of time." Well did the Egyptian write over the Temple of Isis: "I am whatsoever has been, whatsoever is, and whatsoever shall be, and the veil on my face no mortal hand has ever raised." In addition to inherited tendencies there is the influence of nutrition and environment during the period of intra-uterine life. During the period when nerve and nerve cell are being shaped out of germinal plasm the progress of development cannot be indifferent to surroundings.

What are the essential features or characteristics of a neurosis or psychosis in a child? In attempting to answer this question we must bear in mind both age and state of health. What may be normal in a child two or three years of age may be very abnormal in a child ten years of age. Then ill-health, over-indulgence, and bad home influence are very apt to bring out the unlovable and "seamy" side of child life. Among the characteristics we may note: 1. Want of coördination in muscular movements both reflex and voluntary. 2. Hyperæsthesia of motor and sensory centres; a slight stimulus provokes a strong reaction out of all proportion to its strength. 3. Failure of inhibitory control over actions or reflex movements. 4. Exaggerated conscientiousness and contrariness. 5. Certain morbid habits not seen in normal children. 6. Tendency to *petit mal* and hysterical attacks. That there is overlapping in these characters is certain, but overlapping is not easily avoided.

In coming to close quarters with the neuroses of early life let me first of all refer to some of those that are very early in evidence and which perhaps depend upon developmental causes. The respiratory centres and also the deglutition centre must be in a condition of functional activity if life is to be maintained, but at times we find that the muscular movements which depend upon these centres are not perfectly performed. The movements depend upon muscle stimulations and inhibitions, which must take place in orderly and regular manner: there must be perfect timing or else there is a hitch. Presumably the movements are controlled by a superintending coördinating centre which is in charge. In congenital stridor there is apparently a failure of inhibition or an active stimulation of the adductors of the cords and the expiratory muscles during inspiration, which is most in evidence during excitement or crying. The cords are more or less approximated during inspiration and stridor results. As the infant grows older the stridulous sound is less and perhaps is only present when deep inspirations are taken as in crying. As a rule infants who are thus affected are perfectly healthy and normal in other ways and the stridor disappears during the second year or before. Infantile stridor is, however, in some cases associated with other defects. In one of my cases the infant had very marked stridor and also a posterior meningocele. Death occurred at five weeks of age during a severe spasm. At the post-mortem examination the naso-pharynx and larynx were perfectly normal. In another case stridor was noticed at birth and later it became clear that the infant had also cerebral diplegia and mental defect. The child had a habit of letting off superfluous energy when excited by forcible inspirations and expirations accompanied by loud stridor. She is now 12 years of age and still has the same habit of forced respirations when she meets a stranger, but years ago the stridor ceased. In another case, that of a boy ten months old, there is marked stridor at times which has been present from birth; this infant has an older brother who suffers from diplegia and athetosis. In both these cases of diplegia I believe the cause was developmental and not due to a lesion at birth. It is no doubt true that in some cases nasal obstruction may give rise to stridor or snoring as suggested by Dr. Eustace Smith, but I think, and, indeed, there is post-mortem evidence to show, that the association is not a necessary one. Excitement and very likely also bronchial and laryngeal catarrh accentuate the stridor.

Deglutition is sometimes performed with difficulty in newly born infants and in young children. Any nasal obstruction—such, for instance, as is present in congenital syphilis—will render swallowing difficult but in other cases there is nothing to explain the difficulty except a failure of coördination. It is not always well marked in breast-fed infants as they cannot draw much into the mouth at a time but mothers will notice the delay in swallowing. The difficulty is most marked when bottle-fed and when the infant is in a great hurry for his food. There are choking and spluttering unless the act of swallowing is performed slowly and with great deliberation. The fluid is "gargled" in the throat instead of being swallowed but there is no necessary return of fluids through the nose as in paresis of the soft palate. Feeding with a bottle is often so troublesome that a teaspoon is resorted to and the mother very soon gives the infant sops. One girl I have watched is now three years old and still has much difficulty with fluids, especially when thirsty and in a hurry to quench her thirst. She has no difficulty with sops but can only get down a few tablespoonfuls of fluid in the day.

The readiness and ease with which infants vomit are well known, the vomiting reflex being always on the *qui vive* and easily excited but in some infants this is very marked. After making every allowance for overfeeding and improper food a certain class remains in which this constant vomiting is due to an over-sensitive or uncontrolled action of the vomiting centre and we can hardly do otherwise than look upon this as a neurosis. Nocturnal bed wetting in children who have long passed babyhood and who have never managed to pass a night in their lives without micturating during sleep strongly suggests a developmental failure of the controlling nerve centres which coördinate micturition. There is an uncontrolled action of the urine-expelling mechanism, or a failure to inhibit.

Head shaking and nodding are also coördination neuroses associated with purposive or instinctive movements which become confirmed into a habit. Attempts to hold up the head and to turn it from side to side or up and down in order to obtain a better view of surrounding objects begin in normal children about the third or fourth month of life. These head movements are necessarily associated with movements of the eyes. They are not voluntary movements in the strict sense, as they are not the result of a clearly pictured idea or revived memory image, but are rather "suggestion reflexes"—i.e., reflexes which come through consciousness.[1] These head-shaking movements may be noted as early as the third or fourth month with the first attempts to hold up the head and to look about, but the infant may not be brought for medical advice for some months after this. Instead of the muscles which move the head and eyes being stimulated and inhibited in a regular and orderly manner the action of the nerve centres is intermittent and produces in addition to the purposive movements constant jerky ones. The tremor becomes more marked, especially the nystagmus when the infant is intently gazing at some attractive object. Probably habit plays a prominent part in confirming the movements. As time goes on and the infant gets into better health and exercises more and more voluntary control the movements gradually cease. These movements are chiefly seen in infants and children of low vitality, and many of them are rickety in more or less degree, but I have not seen these movements in cases of severe rickets. Sometimes they occur for the first time after an illness, such as pneumonia, and in one case related to me nystagmus came on for the first time after an operation for the cure of a hernia. Apparently the stammering, which is likely to come on during the second or third year, is essentially very much on a par with head shaking and is apt to become confirmed by habit.

Another group of neuroses of the lower neurons includes such diseases as spasmodic asthma, recurring fever, recurring vomiting, and perhaps diabetes. All of these are especially apt to occur in neurotic families and give evidence of their presence early in life. The type of spasmodic asthma seen during infancy is usually Henoch's gastric type but asthma secondary to a bronchial catarrh or nasal irritation is also seen. A typical case of asthma in an infant was shown at this society a year or two ago by Dr. W. Ewart and I have recently seen one (with Dr. A. A. Mumford) in which the asthmatic attacks began at the age of eight weeks. The exciting cause appeared to be difficulty of digestion beginning with weaning. The father had suffered from spasmodic asthma as a boy and the infant's mother's brother was also an asthmatic. Between the attacks the infant was quite comfortable, while during the attacks the chest was markedly drawn in at the bases and bulged out at the apices and there was great distress from the dyspnœa. There was no evidence of enlarged thymus. In another case I saw during infancy distension of the stomach with gas preceded the attack which was relieved when the distension passed away with the dispersion of the gas. This patient is now over 20 years of age and has suffered from attacks of asthma all his life. The attacks seem to be excited by some irritation of the terminations of the vagus nerve.

Recurring fever also is apt to occur in members of a neurotic family and to commence in early life. It is well known that in neurotic children the temperature goes up from slight causes or without any apparent cause. In some cases, as is well known, these fever attacks recur again and again at intervals of a few months without being associated with any common or uncommon complaint. The boy's temperature runs up to 104° or 105° F. without any sign or symptom in the chest or elsewhere, he seems fairly comfortable and his appetite is good, the fever continues for some days or a week or more and disappears, leaving him weak and pale for awhile. No doubt in some cases the exciting causes are overfeeding and an accumulation of by-products. These cases are certainly apt to occur in neurotic families and perhaps also tuberculous families, and it is important to note that Dr. G. H. Savage has noticed some cases of mental breakdown in young adults who have suffered from these recurring attacks of high fever.

Let us pass now to some of the minor mental abnormalities of early life which are associated chiefly with the higher level centres. It is not difficult to recognise very early in life that some infants are much more easily aroused than others and are far more sensitive to impressions. All babies cry when they are hungry or have internal discomforts and, speaking generally, the crying reflex is in good order during infancy, but some infants utilise it much more than others.

We all know the neurotic infant: he is a bad sleeper, he is awake half the night, he wants a lot of rocking or walking about, the slightest noise or discomfort awakes him. He is very apt in consequence to be over-fed, as he has no compunction in making his wants known, and gaseous distension of the abdomen and colic aggravate his normally hyperæsthetic disposition. He is early subject to fear, has an exaggerated dread of falling, and starts and clings to his nurse if swayed about. Many of these infants, as I have already said, are troublesome vomiters. Excitement of any sort may start the vomiting reflex. One small girl I knew used to suffer from nausea when the bells of a church close by began to ring for evening service. When about two years old she used to say "Church bells make baby sick," and at times she not only had nausea but vomited. In later years she suffered from attacks of migraine and hysterical half-blindness. She could read the first half of a two-syllable word but not the last half while the headache was present. The same class of child shows perhaps excessive timidity all through infancy and childhood. Every sudden sound makes them start, whether it is the rattle of a spoon or the barking of a dog. At the sight of a stranger or an animal they will turn white and cover up their faces. They have a perfect horror of being stared at and find refuge in a prolonged cry. They dread the sight of the medical attendant who probably reciprocates their feelings. As the child becomes older the timidity becomes a perfect nightmare. They are always seeing uncanny things and have an unwavering belief in ghosts and bogies. R. L. Stevenson must have been thinking of his own childhood when he wrote:

> "The shadow of the balusters, the shadow of the lamp,
> The shadow of the child that goes to bed,
> All the wicked shadows coming tramp, tramp, tramp,
> With the black night overhead."

If daylight relieves them of their fears they return with unfailing regularity with the evening. When they go to bed the room must be lighted and the door open till confidence is in part restored by the nurse coming to bed.

It is for the most part the same class of child who has dreams of the tragic sort. The child during the day has been frightened by dogs or stories about rats or has made the acquaintance of strange beasts in picture books. A marked impression has been made on the visual centres and the images come back during sleep, associated with the curtains or surroundings of the rooms. In rarer cases the hallucinations occur during the day and in the waking hours or in a well-lighted room at night before going to sleep. The child sees animals under the bed or table and will point them out to her mother, absolutely believing in their existence. Or she will call up her mother at night and describe ducks which she has seen in the park in the morning waddling about on the walls of the room.

---

[1] See Mental Development in the Child and the Race, Mark Baldwin, p. 104.

In some children there is, perhaps, not only hypersensitiveness, which shows itself in bitter tears at trifling causes, but a contrariness which makes them difficult to manage. There comes a period in many children's lives when they develop a certain marked determination to disobedience and take apparently the greatest pleasure in doing the opposite to instructions. In some neurotic children this phase becomes almost unbearable. They are spoilt by their parents, who laugh at their odd ways or scold them for the same thing next day, but they generally manage to get the upper hand and to rule the household with a rod of iron.

In another class of child we find a want of control not so much over tempers but over desires and a failure in the growth of an educated conscience. The child emerging from infancy wants every toy he sees, regardless of the rights of others. But as intelligence dawns he gradually shapes his actions in harmony with his surroundings and conforms to the unwritten laws of the society in which he is reared. The child with feeble powers of control gratifies his desires without any regard to others and without any inward sense of shame and will purloin toys, money, jewellery, anything that attracts often in a clever way. Such children are often bright and clever and without a stain on their characters until it is found out that they are habitually stealing from their playmates. They will confess up to just so much as they are obliged and will explain that they cannot help it. In the worst and confirmed class of case they are moral imbeciles and amongst the worst of life's failures.

In yet another class instead of a want of controlling power there is an excessive inhibition over action and desire. These children are too good and very sensitive to reproof. They have a morbid fear of being late at school and lie awake half the night from anxiety lest they should fail to know their lesson next day. They get, perhaps, more morbid as time goes on, accuse themselves of faults never committed, surreptitiously take off marks given them at school by their teachers, are anxious to be punished for sins never committed, or to sacrifice themselves for the good of others.

What is likely to be the future of these erratic and abnormal children? Much depends, no doubt, upon heredity but who can doubt the influence on their career of environment during early life? It is certain that an over-sensitive child will ill withstand the world's buffetings and has more offended feelings in store than fall to the lot of ordinary mortals. But assuming they are carefully tended and there is no evidence of *petit mal* or anything morbid the future is hopeful enough. There is, however, always the fear that a breakdown may come after puberty or during the strain of early manhood or womanhood. In this class we are likely to find hysteria, migraine, and insanity.

The contrary boy is, on the whole, a promising boy if placed under reasonable control. As heretic and reformer he has played his part in the world's history. Some of the ablest and most successful men I know, whose only fault is a weakness for argument, I feel sure once walked through all the puddles on the highway and defied their nurse at bedtime. In those who exhibit a want of control over their desires we have the making of criminals—or shall we say successful business men?—while those with over-sensitive and exaggerated self-control may show in later years the highest forms of self-abnegation, or if they lose their mental balance are only likely to pass through religious excitement to hopeless insanity.

While an over-sensitive nervous system during early life may be accepted as a warning signal, a condition of the senses and feelings which can be described as morbid is at least suggestive of something worse. Among these morbid phenomena may be mentioned the masturbation habit and the dirt-eating habit, while a tendency to eclampsia, marked destructiveness, impulses to scratch and bite, and cruelty to animals may also, perhaps, be included among morbid habits. All through infancy, movements, whether simple reflexes or "suggestion" reflexes in which the stimulation comes through consciousness, tend to repeat themselves when accompanied by a pleasurable sensation and a habit becomes established.

The masturbation habit is not uncommon both in boys and girls as early as the sixth or seventh month of life. Apparently it takes its origin in a hyperæsthetic state of the pudendal nerves; certain instinctive movements follow which give satisfaction and a habit becomes formed. This is seemingly on a par with the teat-sucking or thumb-sucking habit. When hungry or in discomfort the thumb or dummy teat finds its way to the mouth, gives satisfaction, and distracts from the discomfort; this satisfaction is intensified by the sucking movement and a habit is formed which goes on day and night. While both habits are bad it is certain the masturbation habit is doubly so and points to a perverted state of the nervous system. The habit appears more persistent in boys than in girls but this may be, as Dr. J. Thomson has suggested to me, that mothers and nurses discover the habit in boys but not in girls. The infant will cross her legs, work them vigorously, with flexion and extension of the hips, or sit in a chair swaying to and fro till almost exhausted and the perspiration breaks out. Similar movements may go on at night when half asleep. The habit can be broken by a good nurse with a strong personality and persistence; careful attention to health is, of course, necessary. Circumcision may be necessary in boys, though in one case coming under notice masturbation began for the first time shortly after circumcision. Too much need not be made of this habit, especially during infancy, nor need we attempt to judge the morality of the infant by the standard of the older child or adult. He is, after all, only the "raw material of morality."[2]

The dirt-eating habit is another instance of a perverted morbid taste which passes into a habit and may be seen during the first year or later. In its lighter forms it is not uncommon but always uncanny. Perhaps the commonest form of pica consists in picking blankets and swallowing the wool or gnawing clothes; this, perhaps, is associated with strange tastes as regards food and a liking for nauseous medicine. As soon as the child has learned to crawl the range of his depredations becomes more extended and various queer objects are requisitioned for dietetic purposes: plaster from the walls, cinders, bits of paper, slate pencils, with perhaps a special predilection for licking the fender or the blacking off boots. Taken by itself, perhaps, dirt-eating does not mean much but as it is so frequently associated with imbecility and insanity it suggests an abnormal condition of the nervous system. In otherwise normal children the habit is gradually broken as time goes on. No doubt the tendency to imitate which all healthy children acquire and a feeling of shame at practising baby ways help in the way of reform. If, however, as the child grows older he continues to show morbid tastes as regard queer things and if this is associated with other abnormal signs or *petit mal* the future is not so hopeful. Many of these dirt-eating children are sallow and unhealthy looking, suffer from diarrhœa, and all sorts of articles which they have swallowed make their appearance in their stools.

Another habit, more or less morbid, which develops at times in neurotic infants is a trick of suddenly digging their nails into the hands or face of their nurse or anyone who picks them up. It comes too early in life to be described as viciousness; it is rather an impulse which becomes a habit, the child deriving pleasure from noticing the consternation it produces. In most cases the habit is gradually broken as the child grows older. On the other hand, children who are more or less mentally abnormal or weak retain some such habits for years. They may be really dangerous in their ways and quite unfit to play with other children and get a bad character as playmates. The same heedlessness may be shown in their treatment of dogs and other domestic animals; they seem devoid of sympathy and heedless of pain. Such children are given to the masturbation habit and not infrequently suffer from *petit mal*. Their future is none too promising.

Time will not permit of any long reference to the various forms of major and minor epilepsy which occur in children. During early life we are constantly reminded of the close relation which exists between infantile convulsions, hysteria, and the various forms of epilepsy. We see in children forms of slight fits in which there is no complete loss of consciousness, a momentary "faint," a stumbling when at play, or some coördinated movement, such as making grimaces, getting up and sitting down again, which appear at first to the parents as being only "tricks." They might pass for such were there not a temporary pallor, a dazed look, or perhaps at times a real and undoubted convulsion. These minor fits are often more or less under the control of the individual; a sharp word or a shake will ward them off. They tend to grow worse if much notice is paid to them and the child thinks that her fits are a source of interest to the family circle. They tend to cure if treated with wholesome neglect, a scolding, and cold water There is always the fear that they may be really epileptic or drift into a condition in which epilepsy alternates with hysteria. Such attacks are closely allied to epilepsy and occur in families in which some member is undoubtedly epileptic but differ in their type from typical epilepsy inasmuch as there is no complete loss of consciousness, the movements are purposive or coördinated and they are more under the control of the will.

---

[2] See Studies of Childhood, Sully, p. 229.

I am inclined to think that such attacks as I have described tend to get well and the prognosis is much better than in typical epileptic seizures. Let me make perfectly clear that the bad habits and bad ways which I have described, if occurring in otherwise normal children, need not give rise to any great anxiety if they are accepted as warning signals. If, however, they persist far longer than the period of infancy, or when there is a combination of morbid habits or there is any sign of mental feebleness, the future must be regarded as uncertain. Epileptic seizures, however slight, if associated with destructiveness or mental backwardness, are anything but reassuring symptoms as regards the future.

I have already referred to the fact that during intra-uterine life both heredity and environment help to give shape to the human organism. During infancy we have hereditary influences still in the ascendant, but in addition to these we have the added influence of personality and training. The brain trebles in weight during the first year of life and continues to increase with the body weight, and who can doubt that as the nerve centres are being perfected and the nerve paths opened up the influences brought to bear on the individual will materially help to mould the character and shape the future life. "Very early in life," to quote Baldwin, "the infant responds to suggestions of personality. As early as the second month it distinguishes its mother or nurse's touch in the dark. He learns characteristic methods of holding, taking up, patting, and adapts itself to the personal varieties. This is quite a different thing from the child's behaviour towards things which are not persons. I think this is the child's first step towards a sense of the qualities which distinguish persons."[3] The nurse puts the infant off to sleep when no one else can, soothes and quiets him when in discomfort, and appeases him when in fractious mood. During the first few months, when the infant is still in the instinctive stage, the formation of habits begins. In the dim consciousness of these early days he is a creature of habit. The infant easily falls into serviceable or bad or morbid habits. Pleasures and pains lead to motor discharges or instinctive movements, and movements once started tend to become repeated or stereotyped.

It is clear beyond doubt that the personality of the mother or nurse counts for much during the earliest months; the intelligent nurse can form good habits in feeding, care, and hygiene, and break up bad ones, when the careless nurse will absolutely fail or the weak mother utterly despair. When the infant passes into the stage of intelligence or conscious imitation, personality counts infinitely more. The child is made up of two selves, the self of habit and the self of accommodation.[4] The self of habit and hereditary tendencies is the self which dominates the weaker vessel with which he comes in contact. It is the self which he "ejects" into the younger children, the weakling nurse, and the grandmother. He shows on this side the goodness or badness of his breed and education. The accommodating self is the self that learns, that imitates, that is influenced by the stronger character around him, and which he absorbs and transfers to his habitual self. It is the business of training and education to influence the accommodating self. The child finds himself stimulated to control his impulses and his desires by conforming to the will of a stronger and greater personality.

How much of the ultimate result, whether the training and environment be good or bad, depends upon hereditary influences we all must admit. But there are few children indeed of normal intelligence that will not be gradually brought under the influence of those with whom they come in contact. Much depends upon heredity and much on parents. How many are equal to the task? I will not say hard things of the class of parent to whom the nursery is an unexplored country and who give to billiards and bridge what was meant for mankind; rather let me insist on the harm which is done by devoted parents in the direction of over-care and over-indulgence. Every intelligent parent recognises the evils of carelessness; perhaps few think of the evils wrought to the infant or child that is never allowed to lead a natural life and is protected from every wind that blows. Over-anxiety and over-care make a bad school for neurotic children for learning self-restraint and self-control. The child quickly accepts the situation that he is the centre round which all the household moves. He soon learns that he must not be allowed to cry and cry he does till he gets what he wants. With the laudable desire to give pleasure to the children and make them happy they are over-indulged in every luxury and every excitement that appeal to the emotional side of their nature. How great the harm done to the present-day neurotic child by a life of excitement no mortal man can assess. A world-wide authority in an address given the other day said: "Young people should go tired to bed and have no time for unhealthy excitement." And may I with no uncertain voice plead as a cure for the neuroses of the twentieth-century child hard work and hearty play, a simple and a healthy life.

---

THE INFLUENCE OF FEEDING ON THE MORTALITY OF INFANTS.[1]

BY WILLIAM J. HOWARTH, M.D., D.P.H. VICT.,
MEDICAL OFFICER OF HEALTH, DERBY, AND MEDICAL OFFICER TO THE DERBY EDUCATION AUTHORITY.

A CONSIDERABLE amount of work has been done on the subject of infantile mortality and as a result many valuable suggestions have been made. The statistical material, however, so far as it is concerned with the method of feeding, deals chiefly with the relative proportion which deaths among hand-fed and breast-fed children bear to the total infant deaths, rather than the proportion which such deaths bear to the aggregate of children reared in each of these two ways. In the following paper an attempt has been made to obtain these more trustworthy figures for the borough of Derby. The information used for this purpose has been collected by the women inspectors and has been accumulating for some years.

Varying local conditions play an important part in causing differences in the mortality returns of different districts and to make the following statistics of value for comparative purposes it would perhaps be advisable to refer briefly to the existence of those conditions which are generally assumed as having some influence on the mortality of infants, as they exist in Derby. The town is neither markedly salubrious nor notably unhealthy. Its population is chiefly of the artisan class and numbered 115,000 at the last census. Employments are at railway works, foundries, and mills. Trade is fairly constant, without violent fluctuations, and on the whole there is less acute poverty than in most towns of the same size. The percentage of married women engaged in occupation at the census of 1901 was 9·2, as against 13·2 in England and Wales. The slums are extremely limited in extent and overcrowding is practically non-existent. The percentage of tenements with less than five rooms which were found to be overcrowded was 4·1, as against 12·0 for England and Wales and 11·8 for the aggregate county boroughs. The size of the tenements, which practically mean houses in Derby, is satisfactory, as 81·8 per cent. are of five rooms and upwards, as against 46·7 in England and Wales. The town is built on heavy retentive clay and is about 160 feet above the sea level at the market place. The levels and directions of streets are characterised by an unfortunate irregularity. There are a large number of privies and pail closets, the objectionable influences dispersed by which are lessened to some extent by the large open space which is required at the rear of all buildings. These facts indicate that the population is perhaps below the middle in the social scale but the inhabitants live under fairly average conditions.

During the year 1900 arrangements were made whereby information of every birth registered with the local registrar was given each week to the medical officer of health. Since then an inquiry has been instituted into the manner of feeding every child so registered and the following statistics relate to the births which were registered during the three years November, 1900, to November, 1903. These were not submitted to analysis until 1904. By carefully indexing every birth it was possible to trace any dying under the age of 12 months and thus a 12 months' history was obtained of every child born in the town and not removed before the age of 12 months. The fact that no account was taken of emigrants or immigrants will not seriously disturb the results, for we may reasonably assume that among the emigrants the method of feeding the children would probably approximate the totals, and although a lessening in mortality rates would result by excluding them the comparative rates would still remain trustworthy. During the above three years 9189 births were registered. No inquiry was made in 523 instances, as they were births in houses where it was considered possible that the parents might resent inquiry. 17 deaths were observed amongst these latter children. 323 children were born, in respect to which the kind of food could have no influence in causing early death, for 85 of them were children of low vitality who died before nourishment had been given, 206 were prematurely born, and 32 were born with some congenital defect or malformation inconsistent with life. Table I. gives particulars of all these births, subdivided according to the quarter of the year in which they occurred.

---

[1] A paper read before the Derby Medical Society on April 4th, 1905.

TABLE I.—NUMBER OF BIRTHS OCCURRING IN EACH QUARTER (NOVEMBER, 1900, to NOVEMBER, 1903) AND THE DEATHS REGISTERED AMONG THEM UNDER THE AGE OF ONE YEAR; ALSO SIMILAR PARTICULARS RELATING TO THE SAME CHILDREN DIFFERENTIATED ACCORDING TO THE METHOD OF FEEDING AND PARTICULARS OF THE CASES WHICH ARE NOT INCLUDED IN THIS LATTER DIFFERENTIATION AND THE REASONS FOR EXCLUSION.

Quarter of the year in which the birth occurred.	All births.			Breast-fed children.			Hand-fed children.			Children reared partly naturally and partly by hand.			Various.				
														Dead.			
	Total number of births.	Deaths under the age of 12 months.	Death-rate per 1000 births.	Number of children breast-fed.	Deaths under the age of 12 months.	Death-rate per 1000 children breast-fed.	Number of children hand-fed.	Deaths under the age of 12 months.	Death-rate per 1000 children hand-fed.	Number of children not wholly breast-fed or hand-fed.	Deaths under the age of 12 months.	Death-rate per 1000 children so reared.	No information, but living.	No nourishment given.	No information obtainable as to method of feeding.	Premature births.	Congenital defects and malformation.

If the 846 children in respect to whom no investigations were made or who died under conditions impossible to be influenced by the manner of feeding are deducted from the 9189 registered births a total of 8343 children is left, and of this number 5278, or 63·3 per cent., were breast-fed; 1626, or 19·5 per cent., were hand-fed; a nearly equal number—1439, or 17·3 per cent.—were breast-fed at first and afterwards wholly hand-fed or were partly breast-fed and partly hand-fed from a very early stage of their existence.

The highest average death-rate occurred among children born in the second quarter of the year and then in order of diminishing rates in the fourth, third, and first. These death-rates, however, only represent the resultants of causes operating upon each of the three classes into which they are differentiated and on that account it will be more profitable to analyse the returns under the subheadings. The highest death-rate (197·5) is observed among the hand-fed children; it is nearly three times that recorded among breast-fed children (69·8) and it is twice that of children reared partly by hand and partly naturally (98·7). These marked differences are further accentuated by the fact that the mortality-rate among breast-fed children as here stated is in excess of the actual for this reason. The statement made at the time of visitation that the child was breast-fed was made the subject of very careful inquiry before being entered as such but in investigating the subsequent deaths it was found that hand-feeding had been substituted. As the number of children in whom the feeding had been changed from breast to hand could not be ascertained all deaths occurring among such were regarded as belonging to the group among which they were originally classified and thus some deaths which ought to have been included in the mixed or hand-fed group were retained in the breast-fed group.

The mortality among hand-fed children is below the real mortality, for the obvious reason that if it were discovered at the time of the first visit that the child was being regularly hand-fed this method of feeding would not be changed, but several deaths, which perhaps ought to be classified as deaths of hand-fed children, are placed in other groups, thus lowering the mortality amongst this class, so that in comparing the mortality rates in these two divisions the comparison is entirely in favour of hand-fed children and against those breast-fed. It may therefore reasonably be assumed that an average death-rate among infants under one year of age reared naturally ought not to exceed 65 per 1000, whilst the mortality among infants reared by hand is not less than 200 per 1000.

The object of the subdivision of the births into the quarters in which they occurred was to ascertain whether the period of birth had any influence upon the chance of a child living to the age of 12 months, and to assist the elucidation of this question the rates of mortality per 1000 children born in each quarter from the chief causes of death among both breast-fed and hand-fed children have been calculated. These are as follows:—

	Quarters.			
	First.	Second.	Third.	Fourth.
Bronchitis and pneumonia—				
Hand-fed	19·7	27·2	29·2	30·0
Breast-fed	13·0	14·0	14·8	16·3
Diarrhœa and zymotic enteritis—				
Hand-fed	44·4	79·2	53·6	24·6
Breast-fed	9·4	11·0	6·0	7·7
Disorders of the digestive system—				
Hand-fed	51·8	45·3	46·3	38·4
Breast-fed	15·9	15·4	9·7	14·6
Convulsions—				
Hand-fed	17·3	27·2	28·6	27·3
Breast-fed	12·3	13·2	16·3	18·8
All other diseases—				
Hand-fed	44·4	49·8	43·8	60·0
Breast-fed	17·3	16 9	19·7	18·9

Among hand-fed children it will be noticed that those born in the second quarter show the highest mortality and that there is a progressive decrease amongst those born in the third, fourth, and first quarters. The analysis of the chief contributory causes of death plainly indicates that the high mortality among hand-fed children born in the second quarter is due to zymotic enteritis and diarrhœa. The incidence of these diseases on children born in each month has been followed and it is found that the children born in May and June, and to a less degree those born in July, were chiefly affected; and further, that although the months of July, August, and September are months of greatest prevalence, children born in August were among the least likely to suffer. The reasons for this result are probably that less care is taken in preparing the food of children after the first month, and as the resisting power of a child to attacks of zymotic enteritis is an increasing one children of the age of two or three months at the time of greatest prevalence will show greater mortality than those who are older, whilst those born during the period are probably sufficiently well cared for to materially diminish the risk. The comparatively high death-rate amongst children born in the third quarter is, in part, to be attributed to some excess of deaths from zymotic diarrhœa, for which the deaths among the children born in July are responsible, and, in part, to a high death-rate from convulsions. Amongst children born in the last quarter the death-rate from bronchitis and pneumonia is highest. This is what might be expected, seeing that the mortality from chest ailments would bear relation to the varying atmospheric conditions which are generally most trying at this period of the year.

Amongst breast-fed infants those born in the fourth quarter contribute most deaths to the general total and in diminishing degree those born in the second, third, and first quarters. There are no very great disturbing elements in any quarter among children reared naturally, yet, as among the hand-fed children, the mortality from zymotic enteritis and diarrhœa shows some variation, the highest incidence being on those born in the second quarter. It is not considerable and may possibly result from small quantities of milk being given to children to quiet them during the mother's absence or to supplement an insufficient natural supply. Chest ailments are distinctly highest among children born in the fourth quarter and this, to a great extent, accounts for the highest total mortality among this group of children.

The chief conclusion which can be drawn from the above information when each group is separately considered is that the only children exposed to exceptional risk are those reared by hand and born either during the second quarter of the year or during the first month of the third quarter.

TABLE II.—*Mortality per 1000 from Certain Diseases among Children who were Breast-fed or Hand-fed, or who were at first Breast-fed and subsequently Hand-fed (Mixed).*

—	Breast-fed.		Mixed.		Hand-fed.		All three classes.

Totals	368	69·8	142	98·7	321	197·5	831	99·1

The very striking differences in the aggregate death-rates of breast-fed and hand-fed children are also to be observed when the mortality rates from different diseases are similarly compared. A reference to Table II. shows that in not one single instance does the death-rate in any class of disease among hand-fed children even approximate that recorded among children who are breast-fed; the rate is invariably considerably higher. It is not easy to associate an increase of 12 per 1000, or nearly 100 per cent., in the mortality from bronchitis and pneumonia with the manner of feeding, nor would an increase in mortality of 7·6 per 1000, which is over 100 per cent., from zymotic diseases, excluding diarrhœa, appear to be associated with a similar cause, nevertheless the statistics point to this result and the probable reason is to be found in the production of children suffering from what might be termed "lessened power of resistance" or "diminished vitality." That these conditions are not the result of marked differences in social position is shown from the following particulars relating to the house accommodation of 100 children fed naturally and by hand and taken in consecutive order from the register:—

	One or two room tenements.	Three rooms.	Houses of four rooms.	Five or more rooms.
Breast-fed	6	7	27	60
Hand-fed	2	3	13	82

If any conclusion can be drawn from these data it is rather that the hand-fed children are better housed than the breast-fed and perhaps it is justifiable to assume they are of at least equal social position. It is more probable that these enfeebled constitutions are the direct result of improper feeding, for when food constituents are not given to a child in their proper proportions, or the substances which are used are either unsuitable or are used in such a manner as regularly to render them unsuitable, it requires very little imagination to suggest the evolution of a child who will show increased sensitiveness to varying climatic conditions and diminished resistance to attacks of the commoner zymotic ailments. Diarrhœal diseases and deaths from defective nutrition are always quite truly referred to as the chief dangers to which hand-fed children are exposed, but it is quite obvious from the above figures that the numerous other diseases cannot be disregarded, since in the aggregate they form a formidable total and to this extent emphasise the argument against rearing a child by hand except in cases of absolute necessity. Next in importance to zymotic diarrhœa come chest ailments, to which reference has already been made, and then convulsions, a large proportion of which deaths are probably to be associated with disorders of digestion, whilst a large proportion of the deaths from marasmus, atrophy, and debility have their origin in the same cause.

Amongst breast-fed children the causes of death which stand out prominently from the rest are bronchitis and pneumonia and convulsions. The former, to a certain extent, depend upon exposure during early months of life, whilst overfeeding during the first six months and the irritability consequent upon dentition during the latter six months are probably the principal factors in the causation of convulsions. There is obviously room for considerable improvement in the mortality recorded among breast-fed infants, and an attempt to lessen the number of deaths from these two diseases would appear to present the most hopeful chance of success.

Amongst children who were at first breast-fed and subsequently hand-fed, a considerable diminution in the mortality as compared with hand-fed is noticeable, and although the aggregate mortality is considerably higher than that of breast-fed children there are one or two classes of disease in which the mortality is lower. This result obviously points to the advantages which accrue to children who have natural food supplemented by artificial food rather than an entire supply of the latter.

It has been an interesting portion of this inquiry to ascertain the mortality among hand-fed children in relation to the kind of food on which they have been reared. There are numerous difficulties in the way of obtaining absolutely correct information because in many cases two or more different foods have been used but the particulars given in the following table may be regarded as fairly trustworthy. It should be stated that cases in which condensed milk was used with any other food are classified under "mixed" food. With the patent foods the only supplementary food that was permitted was milk and water; any other addition brought that particular method of feeding under the heading of "mixed" food.

TABLE III.—*Showing the Death-rates recorded among Hand-fed Children according to the Kind of Food used.*

Kind of food used.	Total number fed on each food.	Deaths.	Death-rate per 1000 fed on each food.
Milk-and-water only	895	153	177
Condensed milk only	149	38	255
Bread, rusks, oatmeal, arrowroot, cornflour, sago, tapioca, and mixed foods ...	159	40	252
Patent food A	39	7	180
" " B	81	17	210
" " C	45	6	134
" " D	93	19	204
Various patent foods	164	36	220
All patent foods...	(422)	(85)	(202)
Incomplete information... ...	1	0	0
Totals	1626	321	193

From this table it will be seen that the lowest death-rate was among children fed on patent food "C," after which children who were fed on milk-and-water survived in greatest proportion. In the aggregate the various patent foods show a death-rate of 202 per 1000, as compared with 177 for milk-and-water. The composition of these foods is interesting when considered in relation to these statistical details; it shows that very many more children survive who are brought up on malted food in which there is no starch than on such as contains unconverted starch in marked degree, whilst occupying a middle position between the two are the various foods prepared from desiccated cows' milk. Patent food "C" is a farinaceous food in which the whole of the starch has been rendered soluble. It contains no fat; this is supplied by the milk used in preparing it. Patent food "A" contains no starch and is a very fair imitation of human milk. It approximates the composition of dried human milk but is deficient in both proteids and fat. Patent food "D" contains starch which has not been predigested and although perhaps even very young children can digest a certain amount of starch it is not a suitable food before the period of dentition. It is this class of food which forms a large proportion of those classified under "Various patent foods," and, as the results show, they are much less suited for children than the other two.

Children fed on condensed milk show a very high mortality —viz., 255 deaths per 1000 of children so fed—and this is not surprising. The chief reason is, perhaps, to be found in the analyses of these milks, which are as follows:[2]—

	Proteids.	Fat.	Milk sugar.	Cane sugar.
Human milk (average) ...	1·5	3·5	6·5	—
Cows' milk " ...	2·5	4·0	4·5	—
Mixture (cows' milk, 2 parts; water, 1 part)	1·6	2·6	3·0	—
Unsweetened whole condensed milk	8·3	12·4	16·0	—
Mixture (unsweetened whole condensed milk, 1 part; water, 4 parts) ...	1·7	2·5	3·2	—
Sweetened whole condensed milk	9·7	13·7	15·0	37·2
Condensed separated milk	11·5	2·0	13·0	45·8

Unsweetened whole condensed milk if no fat has been extracted, constitutes as suitable an article as cows' milk from which to prepare food for infants, and if care is taken in sufficiently diluting it and making suitable additions no serious objection can be raised against its use, but the fact remains that for some reason or other practically none is used for feeding infants in this town. Analysis shows that to sweetened condensed milk a large amount of cane sugar is added, so that if this milk is diluted to the proportions necessary to bring the proteids and fat to the same standard as average human milk, sugar is in excessive proportion. Condensed separated milk shows almost the same percentage composition as sweetened whole condensed milk, except that the fat is reduced to 2 per cent. Such a milk is absolutely unsuited for the food of infants and its continuous use results in slow starvation of the infant. The death-rate among children reared on bread, rusks, arrowroot, and other farinaceous foods is exceedingly high, being 252 per 1000. This is only what would be expected.

A death-rate of 177 per 1000 amongst children fed on modified milk is not satisfactory. The causes may in brief be stated to be twofold—first, the results of contamination, and secondly, the results of ignorance. The index to the effects of contamination may roughly be stated to be the deaths from diarrhœa and epidemic enteritis, and from ignorance the deaths from various disorders of digestion—viz., gastritis and gastro-enteritis, marasmus and atrophy, and debility. The deaths from the former diseases total 84 and from the latter 74, but to these must be added those resulting from impaired resistance which are the direct consequence of improper feeding, and the fact should not be lost sight of that though contamination acts most disastrously during a limited period of the year, the effects of ignorance are always in operation and, in the aggregate, are probably much more serious.

A consideration of the various ways in which contamination of the milk may result and of the means by which ignorance may be combated is not within the scope of this paper, but two points do seem worthy of reference. One is that the risk of contamination of milk in the homes of the poor in towns where privy middens are a feature is a serious one and it ought to be possible to enforce proper cupboard accommodation for the storage of food. The other is that, although education of girls at school in the subjects of domestic economy and home nursing would be of the greatest value, a very great deal more can be done by instructing the young mother at home as soon as possible after the baby has made its appearance. To do this would necessitate the notification of every birth to the sanitary authority and visitation by a properly qualified person. Such information is received in this town and visits are made with, I believe, the greatest advantage to both mother and child.

The deductions which it appears justifiable to draw from the mortality observed amongst hand-fed children fed on different foods are: that the use of sweetened condensed milk, either whole or skimmed, should be invariably discouraged and whole unsweetened condensed milk should only be permitted when one is satisfied that the milk is being used with a proper degree of dilution and with the necessary additions as in the case of modified cows' milk; also that since the death-rate amongst children reared on patent foods is, on the average, higher than amongst those fed on diluted cows' milk, every attempt should be made to encourage parents to use this latter food and to educate them to an appreciation of the necessity for the additions to, and the dilution of, cows' milk to render it suitable for infant's food. The addition of patent foods to the dietary of very young infants is unnecessary, sometimes dangerous, and always expensive.

In conclusion, it is unnecessary further to emphasise the risks to which hand-fed children are exposed, but it should not be forgotten that these risks are considerably minimised by mixed feeding and that, therefore, every mother who is unable fully to satisfy her infant should be encouraged to continue to feed her child and to supplement any deficiency by means of artificial food and that only in case of absolute and unavoidable necessity should resort be had to hand-feeding alone.

Derby.

SOME REMARKS ON

THREE CASES OF SEPARATION OF THE DESCENDING PROCESS OF THE UPPER TIBIAL EPIPHYSIS IN ADOLESCENTS.

BY G. H. MAKINS, C.B., F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

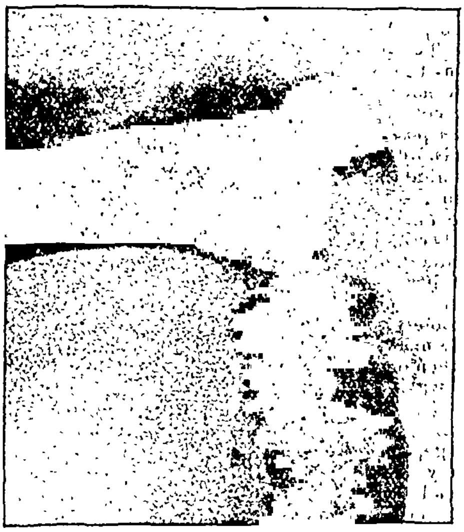
THIS condition, although not uncommon, has only been generally recognised since the use of the x rays has become habitual in cases of bone injury or disease, although one can recall many mysterious instances of "enlargement of the tibial tubercle" in old "out-patient" experience. The following three cases illustrate growing knowledge on the subject. The first, seen in 1897, was mistaken for one of osseous tuberculosis, while in the light of the information gained in its treatment the succeeding two were placed in their proper category.

---

[2] Food and the Principles of Dietetics, by Dr. Robert Hutchison; and Milk and Milk Products, by Permain and Moore.

CASE 1.—The patient, a stout, somewhat flabby boy, aged 14 years, had received a kick over the upper end of the right tibia while playing football a year previously to being seen by me. This injury was followed by severe local pain which persisted for some time and on its cessation as a continuous trouble it recurred with any severe exercise and also occasionally in the form of aching when in bed at night. After the lapse of eight months some local swelling with intermittent pain developed and three weeks before the boy came under my care tincture of iodine was applied which caused slight redness of the overlying skin. A blister was then applied and this was followed by considerable diminution of the local swelling. In November, 1897, the following condition existed. An area of local swelling about one inch in diameter lay over the outer aspect of the tibial tubercle; this was tender on palpation and a sense of deep fluctuation could be obtained. The swelling was strictly localised and there had been no pain since the application of the blister. A skiagram (Fig. 1) was taken by the late Dr. Barry Blacker.

FIG. 1.

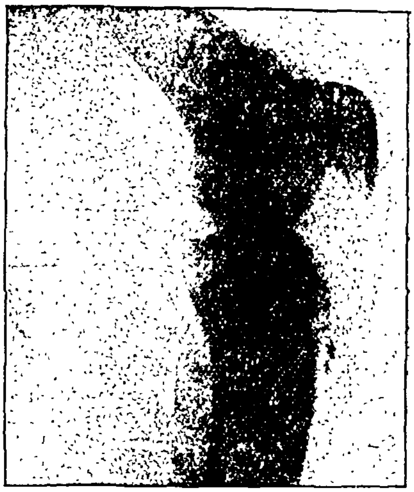


Showing considerable displacement and atrophic appearance.

This showed some gaping of the anterior half of the main junction of the upper epiphysis of the tibia, while a sharp angle existed at the junction of the main mass and the descending beak; two small ossific deposits were seen in the cartilage of the beak itself. The interval between the beak and the upper end of the diaphysis was greatly widened and the latter was more transparent than it should be beneath the space. The prominence of the lower segment of the tubercle was well developed on the diaphysis but no separate ossific centre was visible. The case was regarded as one of local osteitis and tuberculosis being suspected an exploration was recommended and carried out. The operation revealed little; the bone of the upper end of the diaphysis was abnormally soft and a little was scraped away with a Volkmann's spoon but no sign of tuberculous deposit was discovered. The wound healed and after two months of rest the boy returned to school free from any symptoms except occasional aching pain. Violent games were forbidden for the time. Two years later the boy was quite well and free from any trouble.

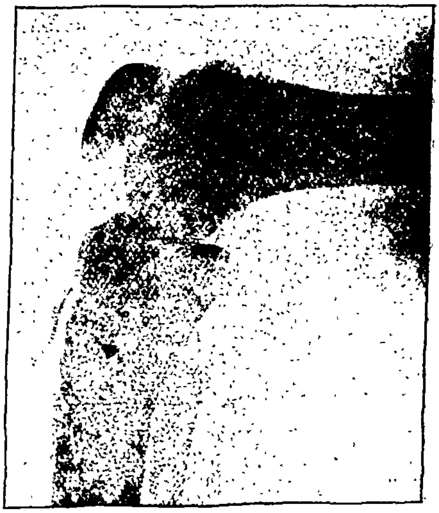
CASE 2.—The patient was a boy, aged 12 years. Towards the end of the football season some weakness and occasional pain were noted in the left knee. For the past six months the knee had frequently "given way" when the boy had been playing games, especially cricket. This "giving way" was attended with pain and the boy with difficulty prevented himself from falling. Two months previously some swelling was noted over the tibial tubercle and 14 days previously a symmetrical swelling was noted in the right limb also. During the whole period there had been occasional pain on movement, especially when the patient had been lying for some time in one position in bed. On examination a symmetrical swelling was observed at the level of each tibial tubercle, there were some local heat and tenderness over the swelling, and on the right side a suspicion of reddening of the skin. Neither swelling fluctuated. Skiagrams of the knees were taken by Dr. A. H. Greg (Figs. 2 and 3) which disclosed the following state.

FIG. 2.



Left knee. Considerable irregularity, slight displacement.

FIG. 3.

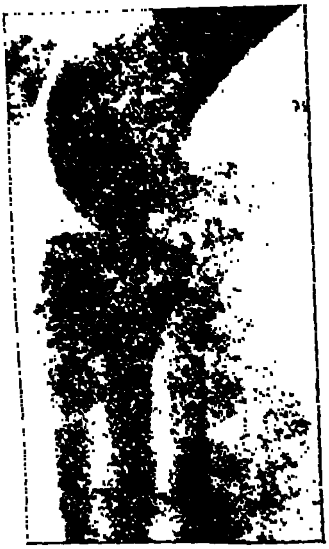


Right knee. Epiphysis almost normal.

The gaping of the anterior part of the epiphysial junction seen in Fig. 1 was absent and the ossific granules in the beak were not so much displaced and formed a continuous line. In both beaks, but especially in the left, a well-marked interruption of the ossific deposit existed at the junction of the beak with the main epiphysis (no obvious angle was formed here). The diaphysial prominence for the lower segment of the tubercle was absent, but the boy was only 12 years of age. Under the influence of rest, local rubbing, and the support afforded by a Velpeau's crêpe bandage the boy improved sufficiently in three months to return to school, violent games being for the time forbidden.

CASE 3.—The patient was a man, aged 22 years, a porter. Four years previously to his coming under observation he had received a kick from a horse on his right leg. Since that period the tubercle of the right tibia had been increasing in size and prominence. At intervals he suffered with pain in the tubercle and he thought that this was particularly the case when the weather was wet and damp and at nights. The knee occasionally gave way and "let him down" and kneeling caused pain. The tubercles of both tibiæ were very prominent but this was much more marked in the case of the left. There was no change in the overlying parts on either side. A skiagram (Fig. 4) taken by Dr. Greg showed the following appearances. The main epiphysis was consolidated with the shaft; in the place of the descending beak two ossific nodules at a higher level than their normal situation were seen in the substance of the ligamentum patellæ and completely distinct from the tibia. The diaphysial portion of the tubercle was well marked and beneath this and for a short distance downwards in the shaft the bone was unduly transparent and offered the appearance of a rarefying osteitis. As the tenderness and giving way were a source of much inconvenience to the patient it was decided to attempt to fix the detached tubercle. With this object a small flap was raised from over the tubercle and an incision was carried vertically downwards through the ligamentum patellæ. The portion of bone was found to be so moveable that the incision was carried through it and a "synovial space" was then found lying between the ligament and the underlying tibia. As it was thought that simple pinning down would probably fail to insure adhesion the osseo-cartilaginous nodule was removed from the tendon and the latter was fixed by suture to the tibia. The terminal attachment of the tendon had not been interfered with. The result has been good and the patient can now kneel without pain.

FIG. 4.



Showing complete displacement. Rarefaction of tibial diaphysis.

The three cases related are of interest as illustrating the various degrees of development of the condition and in showing that the mischief is primarily confined to the portion of the tibial tubercle developed from the epiphysis. It may be useful to add a few words concerning the pathology and symptomatology of the condition.

As has been shown by Schlatter and others ossification of the tubercle of the tibia may be in the form of a continuous extension downwards in the tongue-like prolongation of the epiphysis, or it may follow the appearance of separate ossific nodules in the tongue itself. Further, it is evident that the lower portion of the fully developed tubercle is formed by a projection of the diaphysis at the point of junction of the lower extremity of the epiphysial beak. The latter point is well illustrated by the three skiagrams accompanying the cases. In Figs. 2 and 3, from a boy aged 12 years, no trace of the diaphysial projection is to be seen; in Fig. 1, from a boy aged 14 years, it is obvious; while in Fig. 4 it forms a pronounced eminence. Its development no doubt corresponds with the increasing strain thrown on the diaphysis with the growing strength of the quadriceps extensor.

Causation of the condition.—In Cases 1 and 3 a kick was adduced as the original cause of the trouble by the patients themselves, and in the case of the two boys it is significant that the commencement coincided with the football season. The latter fact emphasises the influence of violent contraction of the quadriceps extensor in the production of the injury. The condition falls into strict coincidence with the rarer one of separation of the tibial tubercle in adults and differs chiefly in the comparatively small amount of displacement of the fragments. This is no doubt to be explained by the fact that the violence has usually been insufficient to tear the lateral extensions of the quadriceps passing to the line running from the tibial tubercle to the tuberosities. The effect of rupture of these extensions in allowing free displacement of the separated tubercle has been pointed out by Osgood[1] and compared with the corresponding result of free laceration of the expansions of the quadriceps and triceps respectively in fractures of the patella and olecranon. In both of the cases related above I should be inclined to relegate the result of the direct kick to the production of an excessive reflex contraction of the quadriceps due to the blow over the patellar tendon. This limitation of the degree of displacement is of practical importance, since it renders implication of the capsule of the knee-joint (a coincident injury seen in fracture of the adult tubercle) unlikely. Naturally the incidence of the condition is confined to adolescence and this of the early stage.

Pathological anatomy.—The influence of the mode of ossification of the tubercle has been already adverted to; suffice it to point out that in all three of the instances under discussion the process was that of the deposit of separate nodules in the beak. The figures show well the progressive change which may take place when the condition is untreated. In Figs. 2 and 3, in which the history was of six months' duration, slight change is to be observed beyond the evident break of continuity at the point of junction of the beak and main epiphysis. In Fig. 1, in which the history extended to 12 months, a well-marked angle has developed between the beak and the epiphysis, while a greatly increased distance separates the beak from the diaphysis. In Fig. 4, where the length of history amounted to four years, the beak has become entirely separated from the epiphysis, forming a kind of sesamoid bone in the patellar tendon, while the tubercle proper is formed from the diaphysis alone. The amount of separation of the beak from the diaphysis has been noted to vary considerably by other observers but whether the sequence of events shown by the above skiagrams is a common one further experience alone can prove.

Another point which deserves mention is the remarkable pseudo-inflammatory signs which are seen to accompany the injury. Thus not only are there local swelling, heat, and tenderness in the soft parts overlying and surrounding the tubercle but the underlying bone of the diaphysis also exhibits signs of rarefaction in an increased transparency. The latter is well shown in Fig. 4 and was existent also in the case forming the subject of Fig. 1, although it is not apparent in the printed skiagram. The inflammatory signs have in many cases given rise to the supposition that a local infective process was present. In a case reported by K. Winslow[2] these signs led to a negative bacteriological and inoculation test being undertaken and in Case 1 tuberculous disease was suspected by myself prior to the operation. In Case 3 the injury resulted in a very imperfect formation of the tibial tubercle, none the less the tubercle was unduly prominent, and it is conceivable that an unduly prominent tibial tubercle may be a remote result of the injury. In this very patient a large tubercle existed in the sound limb. Unfortunately I neglected to obtain a skiagram from it.

Signs of the injury.—The most characteristic clinical indication is the "giving way" of the forcibly extended knee. This seems to be present in all cases and is the more likely to be mentioned by the patient as it is usually antecedent to attacks of pain. The remaining clinical signs are pain, variable in amount and continuity but liable to occur after "giving way" of the knee or on the first movement of the limb after it has been at rest for some time in one position, as at night; local tenderness, elicited on palpation or on kneeling; swelling due to local œdema; and occasionally a suspicion of local redness of the surface. In Case 3 the tubercle was evidently moveable on palpation and manipulation of the tendon.

[2] Annals of Surgery, No. 46, February, 1905.

Treatment.—Rest and local support are the only necessary means when the cases are seen early and recognised. Counter irritation may be useful to relieve pain. Case 2 gives the probable ordinary course of the injury when taken in time.

I cannot defend the exploration made in Case 1 as it was undertaken on a mistaken diagnosis of tuberculous disease of the bone, but it certainly did no harm and I am inclined to think that it hastened the consolidation of the parts. In Case 3 the operation was indicated by the mobility of the tubercle, the long history of four years' duration, and the fact that the condition prevented the man from following his avocation with comfort. The result I consider justified the course followed.

Charles-street, W.

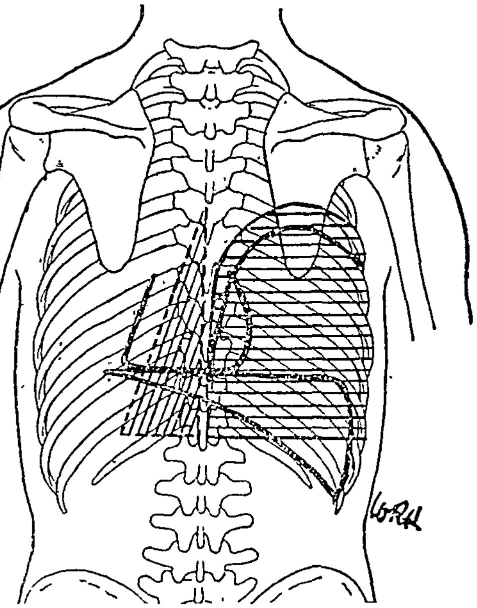
THE PRACTICAL VALUE OF GROCCO'S PARAVERTEBRAL TRIANGLE AS A PHYSICAL SIGN FOR THE DIAGNOSIS AND ESTIMATION OF PLEURAL EFFUSIONS.[1]

By WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN AND JOINT LECTURER IN MEDICINE AT ST. GEORGE'S HOSPITAL; SENIOR PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN.

WHENEVER the size of a pleural effusion is equal to at least a fifth of that of the pleura its diagnosis can be safely established by the major signs at our disposal if we avail ourselves of the mutual confirmation which each of them affords to the others, but when its size is much less than a fifth physical examination does not provide us with the same strict demonstration and the presence of fluid in these small collections has generally to be inferred from the conjunction of suggestive minor signs, symptoms, and clinical circumstances. This was illustrated in two men, aged 26 years and 47 years respectively, recently under my care at St. George's Hospital with small effusions which were not tapped. In the former the fluid was easily identified at first, but at the finish its remainder could not be demonstrated with certainty by the usual methods. In the latter the diagnosis was difficult; and the fluid, which never rose above the lower fourth of the pleura, was not demonstrable by them either during the earliest or during the last stage of the attack. As a fact, owing to the inaccessible position of the *fundus pleuræ* and to its part-occupation by an organ most variable in size, we have not hitherto possessed any fine test comparable to that for small amounts of ascitic or of pericardial fluid. I am led to believe that "Grocco's sign" will now, as a rule, supply that deficiency, as it did in the cases to which I have referred.

I had not realised the capabilities of this interesting sign until it occurred to me to submit it to a crucial test which I found it stood well. I have since then made it the basis of my routine method for the rapid diagnosis of pleural collections, large or small. The fact that it is capable of being checked as to its genuineness in each case and at any moment by the simplest procedure places it on the list of our sure signs, and raises it in respect of trustworthiness even above the analogous sign for pericardial effusion known as the "lower dorsal dull patch"; for in the case of the latter the only crucial test with which I am familiar is its disappearance with the reabsorption of the pericardial fluid. The chief analogy which obtains between these two signs is that, in both cases, the demonstration of the existence of effusion is obtained at a distance from the fluid itself.

Grocco's sign is as follows. Whenever fluid (either pus or serum) collects within a free pleura, a paravertebral patch of partial dulness is obtainable in the other, the "dry" pleura, of triangular outline and of the shape and relative size shown in the diagram, which was kindly drawn for me by my able clinical clerk, Mr. W. R. Harris. *The crucial proof* which I employ to test the genuineness of the triangular dulness is its disappearance when the patient assumes the lateral decubitus on the side of the effusion, and its reappearance immediately he sits up or turns on to the sound side. This is at the same time a demonstration of the significance of the dulness, and for clinical purposes a sufficient proof that its production is due to the influence of a mobile fluid. When, however, the pleura is *over-distended* the mobility of the fluid is much reduced. The complete disappearance of Grocco's triangle does not then seem to occur, judging from one case recently examined by me, but the height of the triangle becomes much less with the change to the lateral posture.



Grocco's "paravertebral triangle" of partial dulness in a case of right pleural effusion. The dorsal dulness of the heart and that of the liver are roughly indicated. The summit of "Damoiseau's curve" of pleural dulness is the level of the apex of the triangle; the relatively narrow base coincides with the twelfth rib.

The short routine method of differential diagnosis which I use on the strength of these observations consists in passing at once to the examination of the sound side of the back as soon as rough percussion indicates a basic dulness resembling that of effusion. If there should be no Grocco's triangle of dulness there can be no free effusion in the chest. Should a Grocco's triangle be found we may then proceed to apply the crucial test if we wish to be further convinced or to convince others that the dulness is really due to fluid. The mode of percussion is a matter of indifference so long as it is good and therefore efficient.

The next question is the *extent of the effusion.* This, too, has its answer in Grocco's triangle. For whereas, as shown by Grocco, the base of the triangle, corresponding in position to the twelfth rib and to the pleural sinus, varies only slightly with the bulk of different effusions (its length ranging between three and six, or even ten, centimetres), the length of the vertical side of the triangle (and, it follows, of the third side also) varies exactly with the upper limit of the effusion. Therefore when a *skilled percussor* determines by two or three strokes, and with great accuracy if he should be familiar with the pleximeter, the height of the triangle and the slope of its third side, which is then to be continued from apex to base with a touch of the pencil, he has not only to demonstrate that fluid has gathered in the chest but also determine its upper level; and he is able, even before percussing critically the effusion itself, to draw in anticipation at the level of the apex of the triangle a Damoiseau's curve which confirmatory percussion will prove to be absolutely correct. It need hardly be pointed out that the exact volume of the fluid within the chest cannot be measured in vertical inches of dulness and in inches of circumference. Its determination requires mathematical accuracy such as that claimed for the colorimetric method turned to clinical account by Schifone[2] on the basis of Niclot's method simplified by Achard. But for our usual clinical needs it is enough that we should know whether we have to deal with a *few ounces or with pints*, and the whole of this information, thanks to Grocco's discovery, can be obtained without any hurry in the space of two minutes.

---

[1] From notes of short cliniques in the wards of St. George's Hospital.

Historical and explanatory note.—It is noteworthy that Banti[3] in 1902 had described the occasional occurrence of a dulness behind the sternum, due to a fluid effusion pressing its way forward. Grocco's communication to the Twelfth Congress of the Italian Society of Internal Medicine at Rome described the triangle; and since then papers have been published in Italy on the same subject, including one by Pieraccini,[4] another by Luigi Ferrannini,[5] who has given much attention to the clinical study of cases and concludes from his discovery of a radioscopic shadow corresponding to the triangle that the dulness is due to local pulmonary condensation under the pressure of a displaced heart, and specially important papers by G. Baduel[6] and by G. Baduel and Siciliano,[7] whose exceedingly thorough anatomical and experimental research is reported in an excellent review in the Epitome of the *British Medical Journal* of Nov. 26th, 1904.

It should be noted that the dulness of Grocco's triangle is of the partial kind only. As shown in my diagram partial dulness also obtains over the spines included in the vertical side of the triangle; and usually there is more of it below than above. The dulness also lessens from the middle line outwards; but it possesses nevertheless a most definite outer boundary which it is our business to percuss out. My former teaching that the vertebral spines are not dull to percussion except when effusion exists on both sides of the chest remains a true statement in the sense that there is not any absolute dulness of the spines in cases of unilateral effusion.

As to the causation it is perfectly clear that there is no underlying fluid at the site of the triangle. Baduel and Siciliano's transverse frozen sections prove this. My own independent observations had led me to recognise in the *mathematical* constancy of the lines a strict analogy with the still less variable lines of the "lower dorsal dull patch" and to surmise that this geometry had in both cases an anatomical basis. It seemed to me, too, that the hydrostatic conditions in the sitting posture would lead to *greater sagging of the pleural sac at* the base,. particularly below the level of the floor of the pericardium, where the mediastinum is looser and the abdominal contents offer only a yielding resistance. I arrived at the conclusion, which I find is entirely borne out by Baduel and Siciliano's transverse sections, that the pleural fluid, whether its amount be small or large, would gravitate to the bottom of the loose pleural sac *and cause its closer* and more extensive adaptation to the vertebræ. These observers have been able to trace a slight shifting of the long axis of the aorta under stress of large accumulations; and they warn us of the danger the vessel might run if a left Grocco's triangle were to be aspirated by mistake.

Paravertebral in its site, Grocco's triangle is therefore in my opinion *vertebral* in its mode of production and is not due, as assumed by Ferrannini, to pulmonary condensation or displaced viscera. It is merely another instance of fluid acting as a mute (as in the production of the "lower dorsal dull patch") and of that pleximetric function of the vertebræ in conducting to the surface amplified or diminished vibrations to which I have for some years called attention. In this case the mute is applied over a portion of the circumference of the vertebræ and the damped vibrations are conveyed to the surface by the compound pleximeter made up of the vertebral spines and transverse processes and of the heads of the ribs. Metaphorically speaking, the dulled spine casts its shadow into the resonant chest; and its shadow grows downwards in proportion to the increasing surface of its contact with the dull fluid which takes the place of dry resonant lung.

This view is strikingly confirmed by my latest observation, made since writing this paper, in a case of pyuria and right lumbar abscess.[8] The presence of a low but rather broad Grocco's triangle in the usual situation led me to diagnose also an empyema as a complication. But no pus was found in the chest, and the triangular dulness vanished as soon as Sir William Bennett's incision emptied the lumbar abscess. The case is valuable as showing that a paravertebral triangle of dulness may be set up at the base of the thorax by a collection of fluid below the diaphragm.

CHONDRODYSTROPHIA FŒTALIS OR ACHONDROPLASIA.

BY H. M. JOSEPH, M.B., B.C. CANTAB.,
RESIDENT MEDICAL OFFICER AT THE HOSPITAL FOR NERVOUS DISEASES, MAIDA VALE, W.

THE importance of a disease to the practitioner increases with its incidence and a rare disease commands little attention. The consequent difficulty in diagnosis must be my excuse for giving this account of a typical case of achondroplasia, a disease sometimes mistaken for rickets but more often perhaps for cretinism.

The patient, a strong healthy girl, aged three years and eleven months, had recently recovered from a severe attack of diphtheria. She had had no previous illness. Several medical men had seen her and she had been treated without result with thyroid extract and also for rickets. There were four other children, all normal. Dwarfism was not known to have occurred in any relative. Although clever at imitation the child's mental condition was below normal. Her speech was indistinct and curtailed, almost restricted to affirmation and negation. Her general appearance was

peculiar. The large cranium with prominent forehead, the depressed nasal bridge and consequent flat appearance of the face, the small chest and prominent abdomen and buttocks, and the short limbs and trident fingers made up a characteristic picture. The measurements of the head, trunk, and limbs, compared with the average of those in normal girls of the same age, will show the more marked features of the case.

The tip of the midddle finger reached only to four centimetres above the great trochanter, while in the normal child it reached nine centimetres below the great trochanter. A small part of this difference was due to the want of complete extension in the elbow-joint—a condition usually seen in these cases.

From these figures it is plainly seen that the limbs and the chest were well below the average and the face measurements slightly below, while the cranial portion of the skull, the abdomen, and the circumference of the hands and fingers were above the normal size. The accompanying photograph displays these characters.

London.

THE DIGESTIVE AND OTHER ACTIONS OF APPLES, PEARS, CHERRIES, STRAWBERRIES, ETC.

BY J. GORDON SHARP, M.D. EDIN.

THE value of the soft fruits as an adjunct to the more solid articles of diet has for long been recognised. The salts which they contain have been regarded as useful in building up the tissues by supplying them in the proper combination required by these tissues, while the succulent and indigestible fibrous material has been recognised as a salutary irritating agent to the gut in persons inclined to constipation. So far good, but the succulent fruits possess other properties not so often appreciated but yet as important as those with which we are already so familiar. The first property may be stated as follows. The organic acids contained in fruit unite with the iron of the more solid foodstuffs to form malates, citrates, &c., and these malates, citrates, &c., are acted upon by the digestive juices low down in the gut, where the iron becomes soluble and active. The great advantage is that the iron in this form is non-irritating. As is well known, much of the iron of our food is lost as iron because it passes out of the gut unused, and unused because it is insoluble. This matters little if the hæmoglobin standard is maintained but in anæmia it is a very important point. Here a suitable dietary made up of proteid and a reasonable supply of fruit may "cure" the condition. As I have already said, the acids of the fruit "fix." the iron contained in the proteid forming organic iron salts which are broken up lower down in the alimentary tract and can be employed by the blood tissue. I know it is denied that the organic preparations of iron are of service in anæmia but from this view I dissent because I have again and again proved its fallacy.

The second property possessed by many of the succulent fruits depends on the presence of a ferment or ferments. I do not mean the ferment common to all living tissue, animal as well as vegetable, such a ferment as will split up glucosides, but I mean rather a series of ferments analogous to those found in the pancreas. We have many familiar examples of the operations of the ferment common to vegetable and animal substances. Tincture of kino when kept from one to two years shows signs of gelatinising and this has been proved to be due to the action of a ferment which is present in the gum kino and the action of which is only developed at the end of a lengthened period. Tincture of digitalis at the end of two years begins to lose its efficacy and this loss is due to the glucosides being split up by a ferment. Another example we find in the bitter almond. Ferment and glucoside lie side by side and remain inactive in the dry state but as soon as water is added the ferment becomes active and splits up the glucoside amygdalin into the well-known aldehyde and hydrocyanic acid. As yet another example of ferment action we turn to the animal tissues and note that when the proteid compounds of silver or other metal are brought into contact with the discharges from the eye or from an open wound the compound is broken up. These are all instances of ferments common to all living tissues and possessing no special action, but my chief purpose in the present paper is to call attention to ferments resembling pancreatine in the animal and papaine or bromeline in the vegetable kingdom. I wish to show that many common fruits contain ferments which play the part of papaine and bromeline (the ferment of pineapple) and that they can digest both egg and serum albumin to some limited extent. The following experiments undertaken to prove or disprove the presence of digestive ferments will indicate the drift of my argument.

I.—THE ACTION OF STRAWBERRIES ON ALBUMINS.

The action of the fresh fruit on coagulated egg albumin.—If fresh ripe strawberries are cut into thin slices and spread in double layers over the bottom of a thin glass dish and on the top of this is placed a thin layer of rubbed-up coagulated egg albumin, and on the top of this another double layer of sliced strawberry, the albumin is sandwiched between layers of strawberry and so is continually moistened by the juice of the fruit. Digestion slowly takes place at the end of eight hours' exposure at summer heat. Evidence of digestion of the albumin is obtained in the following manner. The mass of egg albumin and strawberry is mixed with cold water, stirred up, and the whole is filtered twice through paper when a clear filtrate is obtained. To this filtrate ammonium sulphate is added in excess and a dense precipitate falls and on examination it is found to be a proteid, probably an albumose. Compared with this, similar weights of strawberry and albumin examined without being subjected to digestion yielded very sparing precipitates.

The action of strawberry juice on serum albumin.—In this experiment small masses of coagulated serum albumin (prepared from fresh meat) were placed between treble layers of sliced strawberry and exposed as already detailed in the egg albumin experiments. At the end of eight hours the masses of albumin were found to be softened and eroded all around the outside surface. A watery solution of this serum albumin and strawberry compound was dialysed through parchment and the dialysate on being tested for proteid gave a decided rose pink with copper sulphate and caustic potass. In this and the other experiments no qualitative analyses of the particular proteid found were made but one may say that the mere fact of being able to pass through parchment was alone proof of the presence of a high albumose and consequently of considerable digestive activity in the strawberry juice.

II.—THE ACTION OF RIPE CHERRIES ON BOILED EGG ALBUMIN.

If ripe cherries are split open and the surface of each cherry is covered with a thin layer of coagulated egg albumin that has been rubbed up into a fine pulp and each cherry is again closed and laid in a thin glass dish and protected from dust and then exposed to summer heat for eight hours a considerable degree of digestion is found to have taken place. At the end of this period if these prepared cherries be treated with cold water and the whole then filtered twice through paper the filtrate will, with excess of ammonium sulphate, throw down a very large precipitate of proteid. In a control experiment a like amount of plain egg white and cherries gave a sparing precipitate.

Serum albumin exposed in the same way to split cherries shows rather less sign of digestion than in the egg-white experiments. It should be rather the other way, for serum albumin is generally easier of digestion than egg albumin. Comparing white cherries with black cherries, the former are more active than the latter.

The ferment of ripe cherries.—If the pulp of fresh cherries be extracted with cold water and filtered there is obtained a thick fluid containing proteid material and associated with it the ferment of the cherry. To obtain the preparation in a dry state the fluid is poured into great excess of absolute alcohol and set aside for two months, when the proteid becomes slowly coagulated and it can be collected on a filter and dried rapidly at a low temperature to avoid destruction of the ferment. I have prepared it in this manner and have found it active at the end of two years' time, and its property of splitting up glucosides could be readily demonstrated when a small quantity of the dried preparation was placed in a wide-mouthed bottle along with a teaspoonful of cold water and five grains of amygdalin and the whole set aside at a temperature of 76° F. (24° C.) for from six to eight hours. In time the ferment acts on the glucoside amygdalin whereby it is broken up into oil of bitter almonds (detected by its odour) and hydrocyanic acid. The latter is readily detected if a glass plate with a drop of clear nitrate of silver solution on its inside surface be employed as a cover to the wide-mouthed bottle. As soon as the acid appears in the bottle its vapour rises and acts on the transparent nitrate of silver and changes it into milky cyanide of silver.

The evidence of the digestive action of the dry extract can also be elicited by placing a small quantity of it in a 0·2 per cent. hydrochloric acid solution, adding a small amount of rubbed-up egg white, and keeping the mixture at a warm temperature for eight hours with occasional shaking. The proofs of digestive actions were (1) that when the whole mass was placed on a parchment dialyser the clear fluid which came through gave a pink reaction with a weak solution of sulphate of copper in caustic potass; and (2) the further proof was that the clear dialysate on being thrown into alcohol deposited albumose or peptone or both. The presence of the ferment can also be detected in the fresh cherries by splitting up the ripe fruit and spreading over the cut surface a thin layer of amygdalin and leaving it for a few hours at a temperature of 76° F. (24° C.) when the bitter almond odour develops and the presence of hydrocyanic acid is revealed by the silver nitrate test.

III.—THE ACTION OF ORANGE JUICE ON PROTEID.

Orange juice, freed from all admixture of rind, has a slight digestive action on coagulated egg white and it can be proved in the manner I have already mentioned. If amygdalin be added to the fresh juice the bitter almond odour soon develops. The amount of ferment is perhaps greatest when the fruit is at its ripest.

IV.—THE ACTION OF PEAR JUICE ON COAGULATED FIBRIN.

In this experiment ripe pears were cut open and the cut surfaces covered with a thin layer of coagulated blood fibrin and then closed again and exposed at summer heat in a thin glass vessel for eight hours. The clot gradually became softened and finally quite dissolved. The addition of 0·2 per cent. hydrochloric acid to the juice did not help but rather retarded the digestive action of the pears.

V.—THE JUICE OF RIPE APPLES.

The juice of ripe home-grown apples acts much in the same way but less powerfully than pear juice. This part of the subject naturally leads to the consideration of tinned fruits and at once I may say that all tinned fruits are inert as digestives. The prolonged high temperature necessary to their preservation destroys the ferments. On the other hand, baking or stewing fruit does not entirely destroy the ferment unless the heat be very prolonged. A test as to whether or not a cooked fruit is inert is to be found in the presence or absence of the original flavour of the fruit. If a cooked fruit has lost all its flavour then one may say it has lost all its ferment.

PRACTICAL APPLICATION OF THE FOREGOING EXPERIMENTS AND OBSERVATIONS.

To obtain most benefit from the succulent fruits they should be eaten at the end of the chief meal. This is a general rule to which, however, there are some exceptions. Bananas, for example, perhaps have little digestive activity, and besides they are as much a food as a fruit. They may be eaten with any meal and to many people they are most acceptable when they are cut in thin slices and eaten with bread-and-butter. When not quite ripe they may be placed in a hot oven till they are soft. In the same manner apples may be baked in an oven or roasted in front of the fire. Either of these methods preserves the flavour of the fruit.

Stewed fruit is often recommended as a stimulant to the lethargic gut in constipation but in nine cases out of ten no directions are given for its proper use or if directions are given they are of a character little likely to benefit the condition which they are intended to relieve. Six or eight stewed prunes eaten half an hour before breakfast often prove laxative later in the day, while double the number eaten with or after a meal may have no effect as an aperient. Stewed figs or apples may also be eaten before breakfast in cases where the stomach can tolerate them and where the desire is to get a laxative effect with the greatest degree of certainty.

In our climate we cannot enjoy the luxury of ripe oranges but we can obtain a good substitute by eating the fruit in the shape of a salad. If the orange is peeled and then cut into thin slices so that the juice is set free and castor sugar be strewn over the cut slices it is not unlike pine-apple and as an aid to digestion is highly efficacious. Many fruits if eaten when the stomach is comparatively empty give rise to acidity. Grapes are especially harmful in this direction and it is well to bear in mind that grapes should be eaten at the end of the chief meal of the day.

By an intelligent recommendation of the proper use of fruit in our dietary the medical man can do much to counteract the evil influence of those who teach the entire use of fruit as an article of diet. Every medical man now and then comes across patients who have dined for weeks on half a dozen bananas, a pound of strawberries, a pound of uncooked apples, or a pound of grapes or other fruit. Strange to say, it is often the poor creature who is run down who takes to this fruit craze and, as might be expected, the injudicious feeding makes his condition worse. The importance of many of these points I am afraid is not sufficiently appreciated by medical men. Patients nowadays expect us to give them hints not only on what they should eat and what they should avoid, but likewise as to the manner in which their food should be cooked and eaten. We shall do well if we use wisely the new power given into our hands.

Leeds.

ORAL SEPSIS AS A CAUSE OF IRITIS.

BY E. KENNETH CAMPBELL, M.B. EDIN., F.R.C.S. ENG.,
SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL.

SYPHILIS and rheumatism have become assigned in ophthalmic literature as the more or less stereotyped causes of iritis, the former for the plastic and the latter for the serous. The ascription of any particular disease to syphilis is often a mere refuge for one's ignorance—*obscurum per* *obscurius.* "Rheumatism" is an indefinite word, often loosely applied, and has, in fact, no precise scientific meaning. Apart from rheumatic fever (due to a specific microbe) and gonorrhœal synovitis (due to the gonococcus), the term "rheumatic" is used vaguely by the surgeon as connoting two special attributes: (a) pain and (b) relapse. With regard to rheumatic fever itself I have never known a case to be complicated by iritis and neither have I met with anyone who has. In children rheumatic fever is very common though iritis is very rare.

There is a lack of scientific evidence of any real etiological connexion between iritis and gonorrhœal synovitis, and I have never seen an instance in which their conjunction has been unequivocal. Certainly one occasionally comes across a case of iritis associated with what has been wittily phrased as that "one touch of rheumatism which makes the whole world kin." The pathology of this ordinary chronic rheumatism is obscure: physicians tell us that it is often incipient or mild rheumatoid arthritis, due no doubt to the action of some toxin which has a predilection for the joint structures. But as this kind of rheumatism is exceedingly common its causal connexion with iritis is open to the objection of the *post hoc ergo propter hoc* fallacy. Adopting the thesis that all disease is the direct result of the action of toxins, in elucidating the causes of iritis our inquiry must be directed as to the "port of entry."

At the last meeting of the British Medical Association Dr. William Hunter further elaborated his well-known views with regard to oral sepsis as a cause of disease. In his very luminous exposition of the subject Dr. Hunter enumerates several diseases which he refers to this cause. He omits, however, all mention of iritis. Since the publication of the paper in question I have seen three cases of iritis in which there was an absolutely negative history of either syphilis or rheumatism in any shape or form. In all the three there was marked evidence of oral sepsis; the alveolar margins along the whole line of teeth were red and inflamed, the gums bled easily, on pressure small beads of pus welled up (pyorrhœa alveolaris), and the breath had a sour smell. They all had the dirty sallow complexions suggestive of septic anæmia. The treatment adopted was the following: the teeth were scaled, stopped, or extracted, suppurating pockets were purified, and the mouth was rendered as pure as possible. This, combined with the use of mydriatics and tonics, cured all the three cases rapidly.

In conclusion, I would therefore urge that the constitutional treatment of iritis should be directed to the removal of oral sepsis, for though about 50 per cent. of cases of iritis are undoubtedly due to syphilis yet even here we must admit the possibility of a mixed infection. In the words of Professor J. Miller: "Their custom—i.e., physicians'—to disregard dental diseases altogether as a factor in pathology is as unjust to their patients as it is discreditable to their profession."

29 YEARS OF CATHETER LIFE.

BY R. HINGSTON FOX, M.D. BRUX., M.R.C.P. LOND.

THE patient was a man of massive frame, 6 feet 2 inches in height. He had been accustomed all his life to outdoor pursuits, was very regular in his habits, and had been an abstainer from alcohol and tobacco for many years. When aged about 60 years he began to have difficulty in passing urine and it used to dribble away from him. Later he was examined by Mr. Buxton Shillitoe who found the prostate gland enlarged but passed a catheter without difficulty. The patient soon learned to use a soft gum-elastic catheter for himself and from this time to the end of his life (29 years) he never passed without its aid any urine beyond a few drops. He passed a catheter several times a day and took little or no precautions against sepsis.

About 15 years ago when using the catheter in a hurry he made a false passage, bled freely, and could not relieve himself. As his local medical attendant was unable to pass the catheter Mr. Shillitoe was summoned and succeeded in doing so, relieving him of much clot. After this there was no further difficulty for many years. He retained considerable activity of body and engaged in public duties as an alderman of his county and otherwise until he was about 90 years old. He fell and fractured a fibula at the age of 80 years and fractured the femur of the other leg ten years later, recovering sufficiently to walk in his garden with two sticks.

The patient received the careful attention of Dr. Edmund E. Goodbody in his later years who reports that he took cold some weeks before his death, causing inflammation of the bladder and prostate. For the last eight or ten days there was free hæmorrhage after the use of the catheter and this weakened him much. Attacks of pain at the neck of the bladder occurred and in one of these he died suddenly on Dec. 10th last. He was aged 91 years and four months and had depended on the daily use of the catheter for 29 years. There was no examination of the body.

A CASE OF MYXŒDEMA WITHOUT LOSS OF HAIR.

BY CHARLES W. CHAPMAN, M.D. DURH., M.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

THE patient, a woman, aged 48 years, the mother of three children, came under my care in October, 1904. She complained of increasing inability for exertion of mind and body, unsteadiness of gait, great impairment of memory, tendency to fall asleep in the chair at any time of the day, severe lumbar pains, neuralgic pains followed by numbness down both arms, especially the right, loss of appetite, menorrhagia, and general puffiness. Her general health had been very good up to five years previously, when the menstrual loss became excessive and the periods recurred with increasing frequency until the patient was never more than from eight to ten days free. The flow was so profuse as to necessitate complete rest in bed for the first three days. A gynæcologist was consulted who, finding no growth or other abnormal condition of the uterus, attributed the symptom to the change of life and prescribed an ergot mixture to be taken during the periods.

On examination there were general puffiness with large supraclavicular pads, large tongue, flushed cheeks, and the external canthi were sloppy-looking from mucin (a sign of myxœdema to which I called attention some years ago)—in fact, the whole appearance was typical of myxœdema with the exception that there was no loss of hair. On the contrary, the patient had an exceptionally fine head of hair.

The improvement under the usual treatment was soon evident, one of the first signs of which was the marked diminution in the menorrhagia without the assistance of special drugs. The patient is at the present time in a normal state of health and appearance, she can walk for miles, the lumbar pains have gone, and the neuralgia in the arms is fast subsiding.

It is interesting to note that two weeks after the thyroid had been taken the hair combed out more freely than ordinarily for a few days and then this ceased. This circumstance suggests that had treatment been much longer delayed the hair would have suffered. Thinning of the hair is generally one of the early signs of myxœdema. I have seen a fair number of cases of this disease but never one presenting all the usual features of the disease in which the hair was unaffected. This case illustrates how a correct diagnosis may be missed through the absence of one only of the classical signs of a particular disease and, as a consequence, the beneficial effects of appropriate treatment may be needlessly delayed.

A CASE OF CUT-THROAT.

BY JOHN M. BRYAN, L.R.C.P. LOND., M.R.C.S. ENG.

ON Saturday night, May 6th, at about 9.45 o'clock, a sharp pull at my door bell was followed by the entrance of a policeman requesting me to go at once to a case of cut-throat in a house about a quarter of a mile away. Hastily picking up a pocket case and bandages I hurried after him.

On reaching the dark street I was directed by the neighbours standing about to the house. On entering I rushed up the short flight of stairs and found the narrow doorway of a small back room blocked up by the back of a policeman. On squeezing by him I saw that he was supporting a form partly lying on the floor which was covered in blood; another was holding a candle. A glance showed that the patient was quite dead. The police had placed a wet towel round his neck. On removing this I found that a most determined attempt had been made, producing a regular and very smoothly clean-cut wound running transversely right through the thyro-hyoid membrane down to the gullet, without damaging the latter but severing the contiguous large vessels. The cut windpipe was widely gaping and the parts looked pale; all bleeding had, of course, stopped. Both ends of the wound were alike, each end being at a distance of two inches from the tip of the nearest ear. On examining the body afterwards at the mortuary I found that the blood had trickled down inside the shirt as far as the pubes. There was blood also on both hands but no other mark of injury.

It appeared that this young single man, aged 28 years, had been out of work for several months but had got into work again the week before this occurrence. He came indoors partly intoxicated, ate his supper, and afterwards had a few words with his parents because his bicycle had been removed from the hall and carried upstairs to his bedroom, which proceeding put him into a passion, so he went upstairs and cut his throat in the dark. I was informed that the razor was found on a low box on *the left-hand side* of him.

In his remarks to the jury the coroner, who was evidently unaware that it is sometimes difficult to judge of the direction in which the wound is made, whether from the left (the usual direction) or the right side, stated that the medical evidence did not help them much, and went out of his way to say further that he was surprised that a man of my experience should not have noticed sufficiently to be able to state which hand was used (which was not correct). This case illustrates the difficulty which sometimes exists of being able to state from an examination of the wound in which direction the cut is made. There was no evidence or suspicion of foul play and I told the jury that it was my opinion that the injury was self-inflicted.

ROYAL FREE HOSPITAL.

A CASE OF POST-ORBITAL ANEURYSM.

(Under the care of Mr. JAMES BERRY.)

FOR the notes of the case we are indebted to Dr. Mildred I. Burgess, late house surgeon.

The patient, a woman, aged 45 years, married, was dmitted to the Royal Free Hospital on July 18th, 1904. he had had eight children. The last confinement took lace five years ago. Within 12 hours of the birth of the hild she suddenly felt intense pain in the head, chiefly over he right orbit. It was followed immediately by a snap, s if something had burst in the head, and was accom- anied with a loud, rushing sound. Three weeks later her nental condition became impaired. She was sleepless and alkative, mistook identities, and had olfactory and visual allucinations. Proptosis and ptosis of the right eye deve- oped together with complete anæsthesia of the right side of he face. She had great thirst and passed large quantities of rine. She remained at home for the next three months but s her mental condition did not improve she was removed to 3ethlem Hospital. While there she was depressed, being nable to occupy herself or to keep her attention fixed. There was slight rigidity of the extremities. She had hallucinations of vision and smell but these soon disappeared. There was some deafness of the right ear in which she heard a rushing sound and a murmur synchronous with the pulse could be heard with the stethoscope above the right ear. The right eye was anæsthetic; there were severe conjunctivitis and a corneal ulcer. There was further a paralytic internal squint of the right eye. The conjunctivitis and ulcer disappeared under treatment.

Mentally the patient was an ordinary melancholiac. Her mental condition slowly improved but the physical signs were present when she was discharged. On regaining her reason she became conscious of a rushing, hissing noise in the head which she likened to the sound of a saw-mill. She said that she could stop this by pressure on the neck. Since this time till admission to the hospital she was troubled with the following symptoms: (1) Severe pain in the head, always present, but varying in intensity, sufficiently great to prevent sleep and to require morphine daily; (2) a rushing noise in the head; (3) impairment of vision in the right eye; (4) loss of sensation and movement in the right eye; and (5) anæsthesia of the right side of the forehead, the upper part of the right side of the face, and the top of the head. The family history was of no interest. There was no insanity in the family. The only point of interest in the past history was the fact that after a confinement nine years ago she had a hæmorrhage from the right ear.

On admission the patient was stout, pale, and unhealthy-looking; the skin was waxy and the mucous membranes were anæmic. Examination of the urine pointed to a condition of chronic interstitial nephritis; its specific gravity varied between 1010 and 1012; a faint trace of albumin was present; the urea was 0 8 per cent.; the average amount of urine was 40 ounces per diem. The heart's action was extremely feeble, the sounds being very faint. No murmurs could be detected. There was nothing abnormal in the lungs. The right eye presented the following appearances: proptosis and ptosis; an oval ulcerated patch over the lower part of the cornea and below this a leash of injected vessels. The cornea was insensitive. The pupil did not react to light or accommodation. There was no discolouration of the iris; it dilated under atropine. The upper eyelid could not be raised to the full extent but the eye could be completely shut. The sight was impaired owing to corneal ulceration. Pulsation in and around the eyeball was not detected. The ophthalmoscopic appearance of the disc could not be made out owing to the blurring of the cornea. Over the right temple a distinct but distant systolic bruit could be heard. Examination of the cranial nerves on the right side showed the following to be affected: third and fourth, paresis of the muscles supplied by these—i.e., some ptosis, weakness of the internal rectus, poor rotatory movements. The up-and-down movements were good. Sixth, complete paralysis of the external rectus. Fifth, the ophthalmic and superior maxillary branches were affected—i.e., anæsthesia of the cornea and the face. The muscles of mastication were unaffected. The other cranial nerves were normal. There was no interference with the motor and sensory systems in the limbs and trunk. The reflexes were normal. There were no interference with the lumbar centres and no trophic changes.

The following diagnosis was made. Idiopathic aneurysm of the right internal carotid in the neighbourhood of the cavernous sinus involving the sixth, the superior maxillary and ophthalmic branches of the fifth, and the third and fourth nerves partially, probably produced by embolism due to a clot formed in the left auricle, the circulation having been depressed by exhaustion or hæmorrhage consequent on the confinement.

As regards treatment, before admission the patient had undergone a course of treatment with iodides with no result. Mr. Berry proposed to tie the right internal carotid in the neck.

On July 22nd the internal carotid was tied about one inch above the bifurcation of the common carotid. The operation was performed in the usual way and presented no difficulty. After ligature no alteration in the pulse at the wrist was observed, nor was the action of the heart interfered with in any way. The patient stood the operation well. The after-effects were very satisfactory. The rushing noise in the head ceased from the time of the operation. The patient could not hear it nor could a murmur be detected with the stethoscope. There were no mental symptoms. She still complained of pain but slept without morphine. The *obscurius.* "Rheumatism" is an indefinite word, often loosely applied, and has, in fact, no precise scientific meaning. Apart from rheumatic fever (due to a specific microbe) and gonorrhœal synovitis (due to the gonococcus), the term "rheumatic" is used vaguely by the surgeon as connoting two special attributes: (*a*) pain and (*b*) relapse. With regard to rheumatic fever itself I have never known a case to be complicated by iritis and neither have I met with anyone who has. In children rheumatic fever is very common though iritis is very rare.

There is a lack of scientific evidence of any real etiological connexion between iritis and gonorrhœal synovitis, and I have never seen an instance in which their conjunction has been unequivocal. Certainly one occasionally comes across a case of iritis associated with what has been wittily phrased as that "one touch of rheumatism which makes the whole world kin." The pathology of this ordinary chronic rheumatism is obscure: physicians tell us that it is often incipient or mild rheumatoid arthritis, due no doubt to the action of some toxin which has a predilection for the joint structures. ROYAL FREE HOSPITAL.

A CASE OF POST-ORBITAL ANEURYSM.

(Under the care of Mr. JAMES BERRY.)

FOR the notes of the case we are indebted to Dr. Mildred M. Burgess, late house surgeon.

The patient, a woman, aged 45 years, married, was admitted to the Royal Free Hospital on July 18th, 1904. She had had eight children. The last confinement took place five years ago. Within 12 hours of the birth of the child she suddenly felt intense pain in the head, chiefly over the right orbit. It was followed immediately by a snap, as if something had burst in the head, and was accompanied with a loud, rushing sound. Three weeks later her mental condition became impaired. She was sleepless and talkative, mistook identities, and had olfactory and visual hallucinations. Proptosis and ptosis of the right eye developed together with complete anæsthesia of the right side of the face. She had great thirst and passed large quantities of urine. She remained at home for the next three months but as her mental condition did not improve she was removed to Bethlem Hospital. While there she was depressed, being unable to occupy herself or to keep her attention fixed. There was slight rigidity of the extremities. She had hallucinations of vision and smell but these soon disappeared. There was some deafness of the right ear in which she heard a rushing sound and a murmur synchronous with the pulse could be heard with the stethoscope above the right ear. The right eye was anæsthetic; there were severe conjunctivitis and a corneal ulcer. There was further a paralytic internal squint of the right eye. The conjunctivitis and ulcer disappeared under treatment.

Mentally the patient was an ordinary melancholiac. Her mental condition slowly improved but the physical signs were present when she was discharged. On regaining her reason she became conscious of a rushing, hissing noise in the head which she likened to the sound of a saw-mill. She said that she could stop this by pressure on the neck. Since this time till admission to the hospital she was troubled with the following symptoms: (1) Severe pain in the head, always present. but varying in intensity, sufficiently great to prevent sleep and to require morphine daily; (2) a rushing noise in the head; (3) impairment of vision in the right eye: (4) loss of sensation and movement in the right eye; and (5) anæsthesia of the right side of the forehead, the upper part of the right side of the face, and the top of the head. The family history was of no interest. There was no insanity in the family. The only point of interest in the past history was the fact that after a confinement nine years ago she had a hæmorrhage from the right ear.

On admission the patient was stout, pale, and unhealthy-looking: the skin was waxy and the mucous membranes were anæmic. Examination of the urine pointed to a condition of chronic interstitial nephritis; its specific gravity varied between 1010 and 1012; a faint trace of albumin was present: the urea was 0·8 per cent.; the average amount of urine was 40 ounces per diem. The heart's action was extremely feeble, the sounds being very faint. No murmurs could be detected. There was nothing abnormal in the lungs. The right eye presented the following appearances: proptosis and ptosis; an oval ulcerated patch over the lower part of the cornea and below this a leash of injected vessels. The cornea was insensitive. The pupil did not react to light or accommodation. There was no discolouration of the iris; it dilated under atropine. The upper eyelid could not be raised to the full extent but the eye could be completely shut. The sight was impaired owing to corneal ulceration. Pulsation in and around the eyeball was not detected. The ophthalmoscopic appearance of the disc could not be made out owing to the blurring of the cornea. Over the right temple a distinct but distant systolic bruit could be heard. Examination of the cranial nerves on the right side showed the following to be affected: third and fourth, paresis of the muscles supplied by these—i.e., some ptosis, weakness of the internal rectus, poor rotatory movements. The up-and-down movements were good. Sixth, complete paralysis of the external rectus. Fifth, the ophthalmic and superior maxillary branches were affected—i.e., anæsthesia of the cornea and the face. The muscles of mastication were unaffected. The other cranial nerves were normal. There was no interference with the motor and sensory systems in the limbs and trunk. The reflexes were normal. There were no interference with the lumbar centres and no trophic changes.

The following diagnosis was made. Idiopathic aneurysm of the right internal carotid in the neighbourhood of the cavernous sinus involving the sixth, the superior maxillary and ophthalmic branches of the fifth, and the third and fourth nerves partially, probably produced by embolism due to a clot formed in the left auricle, the circulation having been depressed by exhaustion or hæmorrhage consequent on the confinement.

As regards treatment, before admission the patient had undergone a course of treatment with iodides with no result. Mr. Berry proposed to tie the right internal carotid in the neck.

On July 22nd the internal carotid was tied about one inch above the bifurcation of the common carotid. The operation was performed in the usual way and presented no difficulty. After ligature no alteration in the pulse at the wrist was observed, nor was the action of the heart interfered with in any way. The patient stood the operation well. The after-effects were very satisfactory. The rushing noise in the head ceased from the time of the operation. The patient could not hear it nor could a murmur be detected with the stethoscope. There were no mental symptoms. She still complained of pain but slept without morphine. The stitches were removed on the sixth day. Primary union resulted. The patient was discharged on August 3rd.

After leaving the hospital the patient was attended by her private medical attendant (Mr. Cyril E. Hogan of Clapham) and was not seen again till Oct. 12th, 1904. She then reported that her general health had been very poor but she had had no return of the rushing noise; the pain was less severe, occurring only in attacks which were lessening in frequency and intensity. The sensation in the face had slightly improved. The local condition of the eye remained the same except that proptosis was not so marked. She died at the end of May, 1905. The kidneys were the cause of all her trouble latterly. The operation was an entire success; there was no further trouble so far as the aneurysm was concerned.

BOLTON INFIRMARY.

THREE CASES OF PERFORATING GASTRIC ULCER.

(Under the care of Mr. R. D. MOTHERSOLE.)

CASE 1.—The patient, a female, aged 22 years, was admitted to the Bolton Infirmary on Nov. 10th, 1900, suffering from gastric ulcer. On Dec. 4th she was seized with a sudden pain in the epigastrium; she complained of great tenderness on pressure over the stomach and there was much rigidity of the abdominal muscles in that region. A diagnosis of perforating gastric ulcer was made and the abdomen was opened in the middle line above the umbilicus. There was no free gas or fluid in the peritoneal cavity and no perforation could be found on the anterior surface of the stomach. It was considered that if a perforation had occurred it was shut off by adhesions and the abdominal incision was closed. The patient's condition improved considerably after the operation and she left the infirmary on Feb. 4th, 1901. After this her stomach continued to trouble her and in June, 1903, she again came to the out-patient department. She was then very anæmic and complained of frequent attacks of hæmatemesis, with much pain in the epigastrium, especially after food. She became an in-patient on June 24th and was then extremely anæmic; her pulse was 130 and her respirations were 40 per minute. There were evidence of cardiac dilatation, a bruit at the root of the neck, œdema of the legs and feet, and enlargement of both the liver and spleen. She complained of occipital and temporal headache. The urine was alkaline, of specific gravity 1006, and contained a trace of albumin. Her condition improved slightly for a time but towards the end of July she had several attacks of hæmatemesis; a very severe one occurred on July 24th, in which she was said to have lost about two pints of blood. On August 11th, therefore, it was decided to operate.

At the operation the tissues were extremely anæmic, the blood was very pale and thin, and considerable oozing took place from the cut surfaces. The stomach was not dilated and no ulcer could be felt on either anterior or posterior surface but the cardiac end appeared to be fixed by adhesions. A posterior gastro jejunostomy was performed in the hope that the ulcer would have a better chance to heal. The patient rallied well after the operation and felt much more comfortable for a few days, with no vomiting and no abdominal pain. On August 15th she was allowed a small amount of peptonised diluted milk and as this was well tolerated she was given a little chicken-broth and malted milk on the following day. But on the 17th she began to vomit and continued to do so frequently until her death on the 21st. The vomit contained a large amount of altered blood. Shortly before her death she complained of severe pain in the epigastrium with much tenderness and marked rigidity but she was then in too bad a condition for any further operation.

Necropsy.—At the post-mortem examination the peritoneal cavity contained a considerable quantity of yellow turbid fluid. The cardiac end of the stomach was firmly adherent to the spleen, which was about twice the normal size. On opening the stomach a rounded aperture was found at the cardiac end of about the size of a five-shilling piece. The edges of the opening were smooth and it led into a cavity in the spleen which extended right through the substance of that organ and on its outer side was only bounded by the peritoneum. This was sloughing and had given way at one point. Nothing could be found on the gastric mucous membrane suggestive of any recent hæmorrhage.

CASE 2.—The patient, a girl, aged 19 years, had for about 12 months suffered from symptoms of gastric ulcer. On Jan. 15th, 1903, about 1 P.M., shortly after her dinner, she was seized with an acute pain in the epigastrium. She went to bed and slept but awoke at 4 P.M. with excruciating pain over the stomach. When seen at 5 P.M. she was in great distress and writhing with pain. There were much abdominal tenderness and muscular rigidity extending downwards below the umbilicus. The diagnosis of gastric perforation was clear and after a hypodermic injection to relieve her distress she was removed to the infirmary. On admission she was obviously collapsed; her pulse was 120, small, and weak. She was operated on at 6 P.M.—i.e., five hours after the onset of the attack but probably only two hours after the first escape of gastric contents.

On opening the peritoneum some turbid fluid and a little gas escaped. The perforation was on the anterior surface of the stomach a little to the left of the centre and near the lesser curvature. The ulcer, or at any rate the greater part of it, was rapidly excised with scissors one blade of which was passed into the stomach through the perforation. The whole thickness of the stomach wall was then sewn up with a continuous suture of strong catgut, so that the line of suture was at right angles to the long axis of the stomach. Outside this a continuous Lembert suture of fine silk was inserted. The peritoneum was then cleansed thoroughly by systematic swabbing, a small incision being made below the umbilicus in order to reach the pelvis more easily. A Keith's tube was left in the lower opening but the upper one was entirely closed. The patient's progress was quite uneventful and at no time after the operation did she look really ill. She left the infirmary on Feb. 17th. She has since had some dyspeptic trouble but is now quite well.

CASE 3.—The patient, a man, aged 28 years, was admitted to the Bolton Infirmary on April 11th, 1904, complaining of abdominal pain, vomiting, flatulence, and loss of flesh. His illness began about two years previously with occasional attacks of abdominal pain and flatulence and in October, 1903, he began to vomit after food and to get thinner. The vomit contained altered blood. On admission he appeared to be much emaciated and complained of dull pain in the epigastrium, usually coming on two hours after food and relieved by vomiting about four hours after food. A tumour could be felt in the situation of the pylorus. His weight on admission was 114 pounds, ten days later it had risen to 115½ pounds, but in another eight days it had fallen to 113½ pounds. The case was considered to be one of gastric ulcer with some pyloric obstruction, the stomach being somewhat dilated. It was proposed to perform a gastro-jejunostomy, but at the beginning of May his condition improved, he felt much easier and increased in weight. On May 9th, however, at 5 A.M. he was seized with violent pain at the pit of the stomach. Owing to unavoidable circumstances the patient was not operated on until noon.

At the operation a perforation was found on the anterior surface of the stomach of about the size of a threepenny-piece, nearer the greater curvature than the lesser, and about three-fourths of an inch from the pylorus. The pyloric end of the stomach was much thickened and there were some enlarged glands in the small omentum but the swelling did not seem to be of a malignant nature. The base of the ulcer was slit up with scissors through the perforation in a direction parallel to the long axis of the pyloric end of the stomach when it was found that the little finger could be easily passed into the duodenum. The ulcer was then partially excised. As its lower margin extended beyond the greater curvature it was thought better not to remove the whole of the thickened base of the ulcer in that direction. The edges of the incision were then united by a continuous catgut suture, passing through all the coats, so that the line of suture was at right angles to the pyloric axis. Owing to the rigidity of the tissues a fair amount of tension was needed to bring the edges together. A continuous silk Lembert suture was employed to cover in the catgut suture. The peritoneum was then well sponged out through the one incision, after which the opening was entirely closed. The patient's condition towards the end of the operation was too bad to allow a gastro-jejunostomy to be performed and it was thought that if he survived it could be done later if necessary.

For two days after the operation the pulse remained at about 120 and the patient complained of very severe pain in the epigastrium, probably due to the tension on the sutures in the stomach. After this he steadily improved and soon declared that his stomach felt much better than before the operation. His temperature never rose above 99°F. He naturally lost weight for a time after the operation but as soon as he was allowed food he was always hungry. By June 13th his weight had risen to 122 pounds and when he left the infirmary on June 17th he felt better than he had done for years. Four months later he weighed 152 pounds, and though he said that the scar in the abdominal wall felt weak when he had to lift three-quarters of a hundredweight he maintained that his stomach was "all right inside."

Remarks by MR. MOTHERSOLE.—There can be little doubt that in Case 1 there was a perforation of the stomach in December, 1900. This was probably small and became occluded with lymph which glued the stomach to the anterior surface of the spleen. Ulceration went on and eroded the spleen substance, and it appears certain that the frequent and severe hæmorrhages from which the patient suffered came from the splenic vessels. It does not seem that much could have been done for the patient by operation in August, 1903. The only operation that could have relieved her then would have been excision of the spleen with closure of the gastric opening. And in her condition at that time she could not have stood such a severe operation. In the light of after events it seems unfortunate that a more vigorous search was not made for the perforation in 1900, even to the extent of breaking down the limiting adhesions. This case shows the risks which adhesion of a gastric ulcer to another organ involves. It would seem advisable in most cases when a perforated gastric ulcer appears to have been occluded without operation to search for, and to excise, it in order to prevent subsequent trouble. Adhesion to a solid organ is likely to hinder healing of the ulcer by preventing contraction of the base.

In Case 3 we were fortunate in having the patient in hospital at the time of perforation and though the operation was not performed so soon as it should have been the patient did not have to suffer the pains and other drawbacks of a journey. The operation had the effect of a pyloroplasty and seemed entirely to relieve the gastric retention from which he suffered. It seems a matter for congratulation that a gastro-jejunostomy was not done when first proposed. If perforation had occurred shortly after the symptoms might have been attributed to the operation.

Recoveries after operation for perforating gastric ulcer have of late years been comparatively common and one almost feels it necessary to apologise for publishing such cases. Yet it is worth while to remember that ten years ago such recovery was almost unknown. Mr. A. W. Mayo Robson's first successful operation for this condition was in 1897. About 16 years ago two patients suffering from peritonitis were admitted to the wards of one of the largest London hospitals. Each was operated on by a distinguished surgeon but in neither case was the existence of a perforation of the stomach discovered until the post-mortem examination. Since then abdominal surgery has made immense progress. I must own to having had three unsuccessful operations for perforating gastric ulcer before I met with a success: one of these was very disappointing and lived for nearly a fortnight after the operation, dying from gastric hæmorrhage and hypophrenic abscess. It is satisfactory to be able to say that the last three operations which I have seen for this condition at the Bolton Infirmary have all been successful.[1]

I am glad to find that Robson and Moynihan in their book on "Diseases of the Stomach" speak so decidedly on the point of "absence of liver dulness" in perforating gastric ulcer. "Its presence or absence is void of any significance, and is unreliable as an aid to diagnosis." Personally, I have never attached any importance to the absence of this sign and in at least six cases have not found sufficient free gas in the peritoneum to give rise to it. It is conceivable that absence of liver dulness may be due to any one of three conditions: (1) distension of the intestines with gas, causing them to overlap the liver; (2) the presence of a certain amount of fluid in the peritoneum allowing the bowel to float up over the liver; and (3) free gas in the peritoneum. In the first of Mr. H. S. Clogg's interesting series of perforated duodenal ulcers[2] he states that the clinical phenomena pointed to the presence of free gas and fluid in the peritoneum, but on opening the abdomen he only says that fluid escaped. If no free gas was found at the operation the signs which were considered to indicate its presence were probably due to the presence of fluid with some distension of the bowels.

ROYAL BUCKINGHAMSHIRE HOSPITAL, AYLESBURY.

A CASE OF SURGICAL EMPHYSEMA RESULTING FROM A FALL.

(Under the care of MR. HORACE ROSE.)

For the notes of the case we are indebted to Mr. Russell E. Palmer, house surgeon.

The patient, a boy, aged six years, was taken to the hospital with a history of a sudden fall over a step ten or 15 minutes previously. On admission his neck was very much swollen, the swelling extending up both sides of the face, and involving the lower right eyelid which could scarcely be opened. His respirations were 30, the pulse was 100, and the colour was good (although he was said to have been slightly "blue"). There was no wound involving the skin anywhere, the nose was uninjured, and there was no air in the pleural cavities. The swelling was soft, doughy, and gave the characteristic crepitus of air in the subcutaneous tissues. He complained at the time of the accident of pain over the trachea but afterwards of none in any particular region although he was tender over all the swelling. His voice was a little husky and he coughed but little, bringing up neither mucus nor blood. The emphysema extended rapidly and spread to the other eyelids, the whole of the chest wall, and part of the abdomen. The child was kept in bed, no special treatment being adopted. On the evening of the second day he developed a temperature of 104°F. but by the following morning it was normal again. The air was rapidly absorbed and the patient left hospital quite well at the end of a week.

Remarks by MR. PALMER.—The explanation of the emphysema seems to be that in falling the head was thrown suddenly and violently back, rupturing part of one of the intertracheal muscles with the underlying mucous membrane, thus allowing the escape of air from the trachea.

Medical Societies.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on July 12th, Professor A. R. Simpson, Vice-President, being in the chair.—Dr. F. W. N. Haultain read a paper on a series of cases of "Axial Rotation" in its Relation to the Pelvic Generative Organs. He said that the abdominal pelvic organs from their moveable character were liable to rotation of their attachments. Out of 16 cases met with in pelvic abdominal surgery two were associated with uterine growths and in 14 the ovary was implicated. The 16 cases were composed of 12 simple ovarian tumours, one ovarian cyst with pregnancy, one normal ovary, one subserous pedunculated fibromyoma, and one rotation of the entire uterus with interstitial fibroid growth. Twists of the pedicle might for clinical purposes be considered as acute permanent, acute temporary, or chronic permanent. Rotation of the pedicle must interfere with the normal circulation of the affected organ, particularly obstructing the venous return, giving rise to all the conditions associated with venous congestion. In one case intense symptoms arose from a two-thirds axial uterine rotation, yet no acute symptoms arose in another case with a narrow pedicle twisted four times. The symptoms associated with twisting of the pedicle and acute strangulation were intense pain in the abdomen, shock, fever, and rapid pulse; these were the same symptoms as those of acute strangulation of the gut without stercoraceous vomiting. Chronic or slow twists might have none of these symptoms and only became apparent during the progress of an operation. Pain, though frequently met with, might be entirely absent, even with strong adhesions to the surrounding structures. Dr. Haultain gave details of a case where acute symptoms with a temperature of 101·5°F. were produced by a congested hard fibromyomatous tumour

---

[1] Since writing the above we have had two more successful operations for perforating gastric ulcer at the Bolton Infirmary, making five consecutive recoveries. One of these was in a patient on whom I had done a gastro-jejunostomy two and a half years before.

[2] Brit. Med. Jour., Jan. 21st, 1905.

Unfertilised Starfish Eggs, and lastly in this group, the Methods and Sources of Error in Experiments on Artificial Parthenogenesis. On more general problems we find the question, "Why is the regeneration of protoplasmic fragments without a nucleus difficult or impossible?" The answer of the author is "that the nucleus is the organ of oxidation of living matter and that fragments of cells without a nucleus are not able to regenerate because their oxidative activity has fallen to too low a point. Such pieces die slowly from asphyxia." The author does not believe that without the nucleus all processes of oxidation cease in the protoplasm; it is only markedly decreased.

Amongst other questions of interest are the following. "Has the central nervous system any influence upon the metamorphosis of larvæ?" The author finds that in Amblystoma larvæ at least division of the spinal cord behind the cervical region did not have even the slightest effect in a single instance upon the processes of development. Akin to the subjects of heliotropism and geotropism is "The Theory of Galvanotropism" (1896), as exemplified on the polar stimulation by the constant current of the glands of the skin of Amblystoma. The author finds that stimulation always occurs at the anodal side of the central nervous system, an exception to Pflüger's law.

A short paper of four pages, entitled "Physiological Problems of To-day," is well worthy of perusal for its stimulating originality and condensed exposition of the fundamental problems of physiology, being the substance of an address delivered in 1897, when the speaker was limited to ten minutes.

This analysis of the chief contributions is all too short to convey an adequate idea of the wealth of interest set forth in these two handsome volumes. These "Studies in General Physiology" touch the bed-rock of the life-problem and present it from many aspects. It is not necessary to agree with the author in all his views; here can be no question that marked originality coupled with assiduous labour and inventive ingenuity characterise the work of Jacques Loeb. Imagination in the best sense of the word has played its part and subjects, at first sight far apart, have been brought together to yield their quota of evidence to support the views of the author. The students of biology, of physiology, and of psychology will find much in these volumes to excite their scientific imagination and to enlarge the horizon of their view of what is called "General Physiology," and each and all of these students must feel that the University of Chicago has conferred a boon on biologists, while "the men and women of our time and country who, by wise and generous giving, have encouraged the search after truth in all departments of knowledge," must rejoice that these decennial publications—issued in commemoration of the first ten years of the University's existence—form a noble record of work achieved and a happy augury of a rich harvest in the future.

LIBRARY TABLE.

The Annual Charities Register and Digest, 1905. London: Longmans, Green and Co., and the Charity Organisation Society. Pp. ccxxvi.-665, and Index. Price 5*s.*—We can find nothing to say about the fourteenth issue of this excellent work which we have not said about previous issues. Mr. C. S. Loch's introduction is as crammed with information as to the right and the wrong way of giving charity as ever. The body of the book contains details of all sorts and conditions of charitable institutions and organisations—both those rightly so called and a number of others which can hardly be called charities; while the index is a model of what an index should be. Armed with this work and some other of a less "official" type, such as "Charitable Relief," in the series entitled "Handbooks for the Clergy," it will be the almsgiver's own fault if he does not distribute his alms with zeal according to knowledge.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. The Specificity of Antivenomous Sera, with Special Reference to a Serum prepared with the Venom of the Daboia Russelli. By GEORGE LAMB, M.D. Glasg., Captain, I.M.S. New Series, No. 16. Calcutta: Office of the Superintendent of Government Printing, India. 1905. Pp. 18. Price 6 annas (or 7*d.*).—From the experiments recorded in this communication Captain Lamb says that the following conclusions may be drawn: 1. By injecting a horse with pure unheated daboia venom an anti-serum for this poison has been obtained. This serum is of considerable strength and has a marked neutralising effect on all the actions of daboia venom both *in vivo* and *in vitro*. It should be of considerable therapeutic value in cases of bites from this snake. 2. The serum thus obtained is markedly, but not strictly, specific *in vivo;* it had no action on the poisons of five colubrine snakes against which it was tested; it has a certain neutralising action on the venom of crotalus adamanteus but has no effect on the venoms of two other vipers—namely, echis carinata and trimeresurus gramineus. 3. When tested *in vitro* against the hæmolytic actions of the various poisons it is found that this serum has no neutralising effect on this action of any colubrine venom, that it neutralises the venom of echis carinata as well as it does that of the poison with which it is prepared, that it has a marked but not equally great effect on the venom of crotalus adamanteus, and that it has no neutralising action on the venom of another viper—namely, trimeresurus gramineus. Further, when tested *in vitro* against the fibrin ferment actions of various poisons it is found that, while this serum neutralises well its homologous venom, it has no effect on the poisons of four other species, one colubrine and three viperine—namely, (1) hoplocephalus curtus; (2) echis carinata; (3) trimeresurus gramineus; and (4) crotalus adamanteus. 4. These observations confirm the conclusion which was previously arrived at and which receives the support of Noguchi's observations—namely, that an antivenomous serum is markedly, but not strictly, specific and that in treating any case of snake bite the homologous serum must be used.

Lessons on Living. A Reading-book in Physiology and Hygiene. By H. ROWLAND WAKEFIELD, Science Demonstrator, Swansea School Board. London: Blackie and Son. Pp. 240. Price 1*s.* 6*d.*—Nos. VI. and VII. of Blackie's Science Readers are included in this little volume which is one of a series especially adapted for use in schools in which elementary science is taught as a class subject. The present volume contains simple and informal lessons in physiology and hygiene, the instruction being elaborated from a series of incidents in the holiday visit of some boys to the country house of a physician in a delightful village. The lessons are full of interest and are given in a clear and readily assimilable way. The book is well illustrated, it is very attractive, and we wish it a wide circulation. It may be read with advantage by all young people.

Hints to Nurses on Tropical Fevers. By S. F. POLLARD, Sister, Army Nursing Reserve; late Sister, Guy's Hospital. London: The Scientific Press. Pp. 57. Price 1*s.* 6*d.* net.—This little book will answer a useful purpose and will be of considerable benefit to nurses who are going to the tropics. It touches on subjects which are not generally discussed in nursing manuals. The first chapter, "Hints on Going Abroad," is a very sensible one and the advice given in it may be followed safely. The diseases which are considered from a nursing standpoint are malaria, dysentery, abscess of the liver, cholera, bubonic plague, beri-beri, yellow fever, malta fever, dengue, typho-malaria, and prickly heat. The special points to which the attention of nurses is directed are carefully selected and considered and the recommendations made are judicious. The little book may well form part of the equipment of a nurse under orders for the tropics.

Electrical Methods in the Treatment of Affections of the Stomach and Intestines: A Practical Manual for Students and Practitioners. By GEORGE HERSCHELL, M.D. Lond. London: A. Siegle. 1905. Pp. 108. Price 3*s.* 6*d.* net.—The origin of this little book was a series of papers in the *Journal of Medical Electrology and Radiology* from January to July, 1904. The book is not intended for the expert but for the increasing number of medical men who have become interested in the subject. The articles are, therefore, of an elementary character and special attention is devoted to apparatus well within the reach of the general practitioner, but it is assumed that the reader has made himself acquainted with the elementary facts of electricity. Dr. Herschell writes that in the disorders of the digestive system electricity is capable of producing the following results when applied by certain definite methods:—1. It can cure many forms of neurasthenia depending upon defective metabolism, and in consequence some functional dyspepsias associated with it. 2. It will restore tone to the nerve supply of the stomach and intestines and is in consequence the best method with which we are at present acquainted of treating gastric neurasthenia pure and simple. 3. It will diminish the secretion of hydrochloric acid in the gastric juice when in excess. 4. It will diminish hyperæsthesia of the gastric mucous membrane. 5. It will promptly cure certain forms of gastralgia and epigastralgia. 6. Slight degrees of gastric myasthenia can be absolutely cured and the severe form usually much improved—that is to say, retention myasthenia can be often converted into myasthenia without retained food débris. 7. In certain cases of functional hypochylia and anachlorhydria the secretion of gastric juice can be re-established. 8. Constipation depending upon intestinal atony can in most cases be either materially relieved or cured. 36 pages are devoted to clinical histories illustrative of the results which may be expected in properly selected cases.

The Rôle of Modern Dietetics in the Causation of Disease. By J. SIM WALLACE, M.D., D.Sc. Glasg., L.D.S. R.C.S. Eng. London: Baillière, Tindall, and Cox. 1905. Pp. 87. Price 2*s.* 6*d.* net.—This book is a collection of essays which have appeared in the various medical and dental journals. Throughout the work the author insists on the necessity of feeding children in an intelligent and natural way and he shows that many ills are distinctly traceable to defective feeding. Dr. Wallace enters a protest against the excessive use of sugar, remarking that "it has become the fashion to belaud the dietetic value of sugar and to look upon it as an important food, while in reality it should be sparingly used and regarded as a condiment." The value of milk in the diet of children has, he considers, been largely over-estimated and should be recognised as an extremely unnatural food for children over or about the age of two years. He advocates a less highly nutritious diet and a more liberal supply of acid fruits of bitter, pungent, and stimulating principles. Further, each meal, he urges, should contain a large amount of solid matter so as to stimulate the mastication. The book is well worthy of perusal, even though the reader may not be in accord with all the author's conclusions.

JOURNALS AND MAGAZINES.

Bristol Medico-Chirurgical Journal.—The June number of this journal contains some interesting papers. Dr. J. Michell Clarke calls attention to some of the symptoms of Cerebellar Tumours, especially deafness and other disturbances of hearing. Dr. Henry Waldo deals with the Causation and Treatment of Baldness which he connects with seborrhœa and infective conditions attacking the scalp. Dr. Charles Begg in a short article on Sprue records some good results attained by the use of santonin which must be of the yellow variety produced by the action of light upon the drug.

Edinburgh Medical Journal.—The July number contains an article by Dr. G. A. Gibson upon Bradycardia which has already done duty as a paper read before two societies, the British Medical Association and the Edinburgh Medico-Chirurgical Society. Dr. P. McBride writes upon some cases of Sudden Onset of Cephalic Bruit and Deafness, due apparently to aneurysmal dilatation of a cerebral vessel. Dr. Karl J. Fürth and Dr. F. Parkes Weber record a case of Malignant Endarteritis of the Pulmonary Artery occurring after Gonorrhœa, in which a fungating patch was found in the vessel after death. This lesion, which was the only one found, seemed hardly sufficient to explain the existence during life of a long diastolic murmur heard over the pulmonary region. Streptococci but no gonococci were found in the vegetations. In the concluding Morison lecture Dr. John Macpherson emphasises the need for psychiatric departments at general hospitals and also for an extension of the boarding-out system of treatment for many chronic cases.

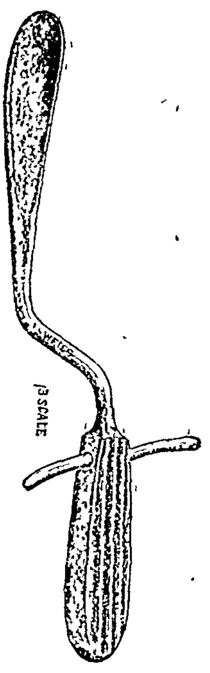
West London Medical Journal (July).—In the Cavendish lecture upon Diseases of the Heart Dr. James F. Goodhart deals, with his usual common sense, with a number of conditions which may give rise to suspicion of cardiac disease but which are in reality "functional" in character. The article is well worth careful study by all medical men and especially by those who have much to do with life insurance work. Dr. W. H. B. Stoddart contributes an interesting paper on the Recognition and Treatment of Mental Disorder in Private Practice and gives some useful advice as to dealing with such cases.

New Inventions.

A SPOON-ELEVATOR FOR RAISING THE PELVIC FLOOR.

Dr. J. G. Garson in 1878 made an important communication to the *Edinburgh Medical Journal* upon the Displacement of Bladder and Peritoneum by Distension of the Rectum. Soon afterwards the suprapubic operation for removal of vesical calculi was resuscitated and for a time Petersen's bag enjoyed great popularity for lifting the base of the bladder by distending the rectum; it was also used in operations for removal of vesical tumours but before long it was discovered that its use was not devoid of danger and that it also caused increased congestion of the bladder by its pressure on all the blood-vessels of the rectum. Owing to the recent successful introduction of the operation of removal of the prostate by the suprapubic route, the surgeon has often wished he could supplement fingers in the rectum by an instrument which would answer the same purpose, although Dr. Eugene Fuller is able to perform his prostatectomies with marked success by simply pushing his closed fist against the perineum. Nevertheless many surgeons feel that it is necessary to raise the prostate by fingers in the rectum, either the operator's or those of a skilled assistant, in order that improved conditions may be obtained for rapid enucleation of the gland; on one occasion I had the privilege of seeing Dr. Proust assist Professor Tuffier in such circumstances, but such skilled assistance is rarely available.

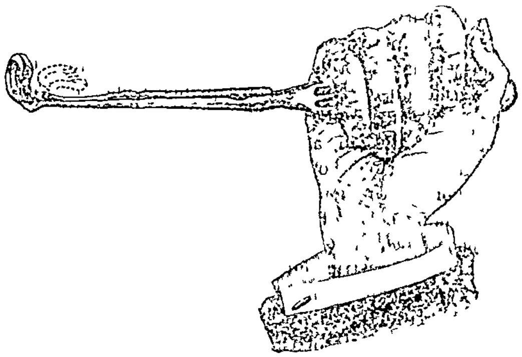
Messrs. Weiss have made for me a spoon which answers this purpose admirably. The illustration shows its chief mechanical points. The spoon is of the sixteenth and seventeenth century shape and is four centimetres across at its widest part. The spoon and the straight handle, which are inserted into the rectum, are made to imitate the length and breadth of two long and large fingers inserted into the rectum. The crank handle is made for the purpose of having the instrument conveniently at hand for manipulation in front of the patient's thigh. The curved processes, one on each side of the handle, are for the purpose of preventing the instrument rolling between the patient's thighs when the surgeon is not using it. As soon as the bladder is opened the spoon is passed into the rectum and the patient's thighs are approximated; under these conditions it will remain *in situ* and quite out of the way. The surgeon can perform all the necessary manipulations without infecting his hands and the instrument answers the purpose better, I think, than the fingers of an assistant in the rectum, because the operator acts directly on the spoon; he can push it up or draw it down to the exact position at which he requires the rectal counter-pressure; it can also be tilted to either side so that elevation of any particular area of the base and posterior wall of the bladder can be regulated to a nicety, for every movement of the handle is transmitted directly to the spoon as it is specially made in one solid piece for that purpose. I have used it in three prostatectomies and in one case of evacuation of blood clots completely filling the bladder. In the latter case the clot was cleared out through a suprapubic wound with great ease and rapidity by means of the spoon in the rectum and suprapubic massage of the abdomen. In a case of prostatectomy upon a friend of Dr. W. T. Edwards, J.P., I was able to remove 47 calculi from a large post-prostatic pouch which I could not otherwise reach with my fingers. In one of the other cases there was a calculus weighing two ounces and its delivery was facilitated by using the spoon in the rectum. In operations upon the female pelvis I introduce the spoon into the vagina and it remains *in situ* until required for lifting the uterus, Douglas's pouch, or the bladder. The particular point at which lifting of the pelvic floor is required is easily obtained. In a case of cœliotomy for soft, friable, and separate malignant growths of both ovaries secondary to carcinoma of the stomach I found it very useful as the tumours would not withstand any traction upon them for delivery. The face of a hysterectomy or of an ovarian stump can be easily manipulated so as to give a better view for its inspection by means of the spoon in the vagina. The reason that I record my short experience of the uses of the spoon is due to the fact that Messrs. Weiss informed me that they had sold several of them after I referred in a PS. to a paper on Prostatectomy to the fact that I had used such an instrument. The instrument which I had used at that time and those which have been sold are only three centimetres wide, but in practice I soon found that this was not broad enough for cases of enlarged cervix uteri or of a very big prostate to hold them firmly during lifting of the pelvic floor, as they had a tendency to slip over to one side. The instrument which is described above is four centimetres wide and is more satisfactory on account of its increased breadth.



Cardiff. J. Lynn Thomas, C.B., F.R.C.S. Eng.

AN ADENOID CURETTE.

The use of a curette for the removal of naso-pharyngeal adenoids, in preference to the various forms of post-nasal forceps, has now become almost universal. Most surgeons who have been performing this operation for more than ten years commenced with some form of Loewenberg forceps and have gradually discarded it for the curette. The curette removes a growth so rapidly and completely that the time occupied is very short and the risk from hæmorrhage is greatly lessened. For those whose dexterity is not maintained by frequent practice the curette is also a much safer instrument. Once introduced behind the soft palate and carefully maintained in the middle line of the body it can be swept backwards and downwards along the naso-pharynx without the slightest risk of wounding any important structure except the projecting adenoid mass. I have never known of any operator reverting to the older instrument when once he became used to a satisfactory form of curette. The original Gottstein form, although it detached the growth, had the drawback of not bringing it away, while there was some anxiety of the detached adenoid mass embarrassing the respiration. This objection was overcome by Delstanche's ingenious idea of connecting a hinged and toothed cage to the curette so as to receive the growth. As fitted to the original Gottstein model the toothed cage did not always appear to give sufficient space fully to receive the growth; it became too "crowded," in fact. Besides, the Gottstein form, to which it was attached, ends below in a V point, so that much of the lateral masses of a large square growth might easily escape the first stroke. The Beckmann curette, with its quadrilateral fenestra, and its curve adapted to the roof of the naso-pharynx, is better suited to embrace the adenoid mass. To this curette I have had fixed a hinged, spring frame, armed with short curved teeth set close together. This will admit a mass of any size and will prevent it from falling out of the curette. For the usual light handle I have substituted a more solid one, which can be grasped dagger-wise. Held in this position it is easier to keep the instrument all the time in the middle axis of the body; there is no uncertainty as to where the cutting edge exactly is when out of sight (which may happen if the curette is held like a pen, when it may easily become rotated in the fingers), and the growth can be more completely shaved off by one firm stroke. When the main growth has been removed an ordinary small Beckmann curette (18 millimetres across), fitted with a stout handle, will be found satisfactory for removing any lateral prolongations which have escaped the caged instrument. Thinking that better work could be done the larger the instrument employed I tried various sizes, including one measuring one inch across. But this proved useless, and one stock size, measuring three-quarters of an inch (20 millimetres) across, has been found the most satisfactory for all well-marked hypertrophies. A smaller curette, measuring 18 millimetres across, can be used for more limited growths, but the ordinary size is quite suitable for children three years of age, as well as for adolescents, the choice of instrument depending more on the size of the hypertrophy than on the age of the patient. This instrument was designed about eight years ago. I am informed that it is the one most generally used in the two chief throat hospitals as well as in many of the special clinics of the general hospitals. It is manufactured by Messrs. Mayer and Meltzer who report that they sell more of this model than of any other. It has therefore had an extensive trial before I ventured to bring it before the profession.



Queen Anne street, W. StClair Thomson, M.D. Lond.

Royal Portsmouth Hospital. — A bazaar, under Royal patronage, which extended over four days, was opened by Lady Northbrook at the Town Hall, Portsmouth, on July 11th. Apart from its success as a bazaar the effort will stand out prominently in the annals of Portsmouth, for it took also the form of a celebration of the centenary of Nelson's great and glorious victory, and the navy and army, with the representatives of civilian life, peacefully observed it by doing all in their power to increase the mayor's fund for building a new operating theatre and a block of wards at the Royal Portsmouth Hospital. It is expected that a sum of £1800 will be realised.

THE LANCET.

LONDON: SATURDAY, JULY 22, 1905.

Small-pox Hospitals in Rural Districts.

THE difficulty of adequately isolating cases of small-pox in thickly populated districts has been the subject of much discussion during the last few months and we have recently devoted two leading articles to the matter in THE LANCET.[1] But it has to be borne in mind that the difficulty of providing isolation accommodation for cases of this disease is in no sense confined to thickly populated urban districts. In so far as actual hospital provision is concerned the problem is more acutely felt in rural than in urban districts, owing more particularly to the smaller rateable value of rural districts. But all rural districts are not thus affected equally and it is in counties where general slackness in sanitary administration obtains and where that slackness is faithfully reflected by the county council that small-pox hospitals are but very inadequately, if at all, provided. An instructive example of this unsatisfactory state of affairs has recently been brought to our notice and although all the facts have not been set before us the main features stand out with sufficient prominence. The Leighton and Linslade urban, and the Wing rural, district councils in their anxiety to insure these districts against an invasion of small-pox combined for the purpose of providing a small-pox hospital. This building was duly procured and erected upon a site held apparently on a yearly lease and now, for some reason which has not come to light, the Wing rural district council has expressed its intention of withdrawing from the combination, there being, it would seem, no clause in the agreement which prevents it from doing so. The result is that the hospital will probably be sold to the highest bidder, together, we presume, with such small-pox infection as may cling to it, and the three districts concerned will be left without any provision for cases of small-pox. This impending dissolution of the combined districts has caused considerable discussion at the meetings of the joint committee and of the Leighton Buzzard board of guardians; and although the folly of the proposed dismemberment of the committee has been insisted upon by some of the more far-seeing members, the general tendency seems to be to let the districts look after themselves and to allow small-pox, should it be introduced, to run riot. The board of guardians has apparently contemplated the purchase of the hospital but, as was pointed out to it by its clerk, it is doubtful whether the purchase would be sanctioned by the Local Government Board or, if sanctioned, whether the hospital could be used for non-pauper cases. The Local Government Board holds, we believe, that it is the duty of the district councils to make the necessary provision for isolation accommodation and that it behoves the boards of guardians, when such provision is made, to arrange with the district council or councils for the isolation of pauper cases. We can only trust that in this instance the Wing rural district council will not, for a matter of some £16 annually, deprive its own district of the protection which the hospital obviously affords.

But the discussion which has arisen around this subject has resulted in other suggestions being made and as these have interest to the country as a whole reference may be made to them. It was proposed by a member of the Leighton board of guardians "that it is expedient that small-pox hospitals should be built and maintained from funds from the national exchequer," and the proposer contemplated that if some 50 hospitals were erected in different parts of the country the total annual cost would amount to between £50,000 and £100,000, an amount which, in his view, was much exceeded at the present time. Part of this proposal was that motor ambulances shou'd be provided, an arrangement which, it was urged, would enable each hospital to serve a large area. Question arose as to the suitability of motor ambulances for this purpose and, as our views are asked upon the subject in the local press, we may say that we see no objection whatever to such ambulances for small-pox provided, of course, that they are properly constructed and not driven at a speed which would be detrimental to the patients. But we are in no sense in sympathy with the proposal that the cost of small-pox hospitals should be borne by the national exchequer and we see no reason why this disease should be regarded in an economical light differently from other infectious diseases. There is already ample power to provide such hospitals and we are surprised to find in the papers which have reached us in connexion with this specific instance that no reference is made to the powers which are possessed by the Bedfordshire and Buckinghamshire county councils (the two councils concerned) for the compulsory combination of districts under the Isolation Hospitals Act, 1893, and if these two county councils are alive to their responsibilities they will, it seems to us, turn this incident at Leighton Buzzard to good account by taking steps to recombine or to group the districts of the joint committee by schemes which would embody such districts if the union is discontinued. As regards the mover of the proposal that small-pox hospitals should be a charge upon the national exchequer we must confess that we should be more in sympathy with *him if* he would use his strong personality to propose and to see carried a motion "that the National Assembly at Westminster should place on the Statute-book a measure for enforcing general revaccination and by this means render special small-pox hospitals unnecessary." In this connexion we commend to the guardian in question a perusal of Dr. R. BRUCE LOW's recent report[2] to the Local Government Board upon small-pox hospitals in Germany. He will learn from this report that owing to the protection afforded by vaccination and revaccination there is no need in the Fatherland for the provision of expensive small-pox hospitals but that when cases of this disease occur they are treated as a rule in one of the buildings of the

---

[1] THE LANCET, June 3rd (p. 1520) and

The Teaching of Hygiene in India.

WHEN we consider the high pitch of civilisation which has been reached by some of the ancient races of man it is not to be wondered at that they should have framed for themselves codes of sanitary laws but it is somewhat surprising that these codes should have contained rules so nearly analogous to those which are the result of modern scientific knowledge. The Bible has familiarised us with the sanitary code of the Hebrews and archæological research has shown us that other Eastern nations were no less advanced in the knowledge of hygiene and sanitation. In the later part of the eighteenth century and the beginning of the nineteenth some accurate knowledge of the Aryan people of India was made accessible to us by the labours of such men as Sir WILLIAM JONES and HENRY THOMAS COLEBROOK and from this time, both in this country and abroad, considerable attention has been paid to the literature of this ancient people. Among a people who had reached a high degree of civilisation and in a country where the climatic conditions were particularly favourable to the propagation and the spread of diseases disseminated both by air and polluted water, we find, as might be expected, that the priestly class, who were the learned men of the time, had laid down rules for the avoidance of disease and the preservation of health. Had the Laws of Manu been fully understood and applied by the later inhabitants of India there can be no doubt that that country would have been less afflicted than it is by many dread diseases—cholera and plague for example. But in India, as in many another country, the wise regulations laid down by the priestly caste for the guidance both of mind and body have been perverted and their original meaning has been forgotten, so that ceremonies which formerly had a meaning and a reason are now become for the mass of the people such that they but "confound and darken" counsel. Even now if the natives could be made to understand the real meaning of the ceremonies which they go through with such superstitious reverence not only would the more ignorant benefit but also the educated people of their own and other nationalities who occupy the country with them.

There are already in existence many societies the object of which is to harmonise the philosophy of the East with the science of the West, a task which, for the present at any rate, seems to be an impossible one; but there is another movement on foot and one from which, if carried out with discretion, great good may accrue—namely, the attempt to educate the less intelligent of the natives of India in the practice and principles of Western hygiene and sanitation by showing them the relation between modern science and the rules laid down in their shâstras. From the office of an Indian periodical, called the *Arya*, a monthly magazine devoted to philosophical literature and science, published in Black Town, Madras, we have received three little pamphlets, reprints from the magazine, the first of which treats of water and health by Dr. P. S. CHANDRASEKHAR of Madras Medical College, showing that the Indian sacred writings contain many passages in strict accordance with modern sanitary science, and the second by the same author dealing with personal cleanliness on similar lines. The third pamphlet, "Notes on Ancient Sanitation," written by Colonel W. G. KING, C.I.E., I.M.S., sanitary commissioner of Madras, shows how the methods of purification adopted by the religious leaders of the ancient Hindoos may be made to harmonise with the teachings of modern science, though the author rightly points out that it is well to remember that these teachings were not meant for municipalities of modern times but for individuals who were scattered throughout the land living agricultural or pastoral lives of much simplicity and by no means grouped in well-populated centres, as at the present day. It is remarkable how these methods utilised natural processes recognised by modern science as due to chemical combination and microbial action. The rules against the practice of breaking clods of earth and tearing grass with the finger-nails might well at the present day be directed against the propagation of the ankylostomum; the direction to the householder to give food very hot would tend to kill microbes and to mitigate the results of contamination by exposure to the air; and the prohibition against the use of food that had been touched by the human foot or by the beak or the feet of birds would help to prevent contamination by disease germs. Perhaps the most remarkable testimony to the wisdom of the old Aryan teachers is to be found in their rules with regard to the use of water. The test of smell, colour, and taste seems to have been recognised early, as was also the possibility of contamination if collected in an inhabited area. The directions against answering to the calls of nature on the banks of, or in, rivers and the ruling "let him not throw urine or fæces into the water, nor saliva nor clothes defiled by impure subsubstances, nor any other impurity, nor blood, nor poisonous things," though disregarded by many of the lower class of Hindoos of the present day, show that their ancestors were possessed of wisdom. No better example of the way in which this ancient wisdom has been perverted by the ignorance of the less educated natives can, perhaps, be given than their belief in the purity of running water. The shâstras teach that a river is purified by its flow, a truth which is in accord with modern science, but many a Hindoo superstitiously holding this belief without understanding its meaning will defile water in the grossest manner and not hesitate to use it for domestic purposes, notwithstanding the fact that just above the site of withdrawal the accumulated filth of all classes and castes is being discharged. Colonel KING's pamphlet is full of interest even to the general reader but we have not space to refer to it further except to say that he deals with the Mahomedan writings as well as with those of the Hindoos.

It should not, then, be difficult to teach the less intelligent of the present-day inhabitants of India that the ancient Hindoos and the early Mahomedans were well acquainted with sanitary and hygienic knowledge which has been perverted by their descendants and to show the absurdity of regarding our present teaching as the offspring of a Western craving for the introduction of new fads. Quotations from the Vedas and the Laws of Manu have been, we believe, reprinted and used with good effect during the recent epidemic of plague. If Colonel KING and those who are working to the same end can convince the less intelligent natives, quote the closing words of the pamphlet, that "it is worth remembering ...... when plague surrounds us ...... that the people who will carry sanitation into their homes and as good citizens uphold it in public must reap health and wealth, and that the penalty of neglect of sanitation is financial ruin and death as proved by the history of every people who have had the temerity to ignore it"—if he and they can do this they will have given a priceless blessing to India and the reward will be great.

Medical Men in the Armies of the Ancients.

THERE does not appear in the Roman classics any very distinct allusion to medical men in the Roman army. The only passages relating at all to the subject consist of a casual remark in one of the military epistles of AURELIAN, two incidental legal observations contained in the law writings of MODESTINUS and in the Codex of JUSTINIAN, an allusion by VEGETIUS to the medical care and expense of the sick in camp, and an expression by GALEN as to the opportunities for anatomical observation presented to the physicians during the German wars. When treating of those who by absence from Rome, and so on, were exempted from some burdens and taxes the jurist MODESTINUS, who wrote in the earlier half of the third century, mentions among others the military physicians (*medici militum*), "because," he adds, "the office which they fill is beneficial to the public, and ought not to be productive of any injury to themselves" ("Corpus Juris Civilis Digestorum," Lib. IV., Tit. 6, Leg. 33, Sec. 2). In JUSTINIAN'S "Corpus Juris Civilis" (Lib. X., Tit. 52), drawn up in the sixth century, there is a series of laws, "De Professoribus et Medicis." The first of these laws exempts the physician of a legion (*Medicum Legionis*) from civil duties when he is absent in the public service. In his work, "De Re Militari," VEGETIUS, who wrote towards the end of the fourth century, devotes a chapter (Lib. III., cap. 2) to the regulation of the health of an army, and incidentally rather than directly alludes to the cure of sick soldiers by the skill of the physicians (*arte medicorum*). Enumerating also elsewhere the duties of the prefect of the camp he states that his authority extended over his sick fellow-soldiers and the physicians who had the care of them and he regulated the expenses relative thereto (Lib. II., cap. 10).

The history of other more ancient governments than that of Rome is not without allusion to the office of army surgeons. HOMER, HERODOTUS, and PLINY each comment on the number and fame of the medical men with which the kingdom of Egypt abounded. DIOGENES LAERTIUS, in his account of PLATO, tells us of PLATO'S sickness when travelling in Egypt and adds that he remarked, like HOMER, that the Egyptians were all physicians. They had, moreover, paid medical officers attendant upon their troops in war, for in describing the status and character of the Egyptian physicians DIODORUS SICULUS specially mentions that, when engaged in military expeditions, the soldiers were cured without fees, the physicians of the army receiving a salary from the State. One instance is referred to in history in which a king of Egypt, when thrown from his horse in battle, wounded and speechless from injury of the head, had his skull trephined by his surgeons. This was PTOLEMY PHILOMETER, who defeated ALEXANDER BALAS, the pretender to the throne of Syria, in the year B.C. 146. According to LIVY the victor himself died after the battle during the attempts of his surgeons to relieve him. Nor is the old classical literature of Greece without references to surgical services rendered to the soldier in war. HOMER describes the double character of army surgeons and warriors as combined in the persons of PODALIRIUS and MACHAON. And when the latter is wounded he puts into the mouth of IDOMENEUS the well-known expression ("Iliad," Lib. XI., v. 514) that the medical man is to the army more valuable than many warriors, knowing as he does how to excise arrows and to apply soothing medications. In the course of the "Iliad" the surgical treatment followed in individual cases among the disabled Greek warriors is sometimes minutely entered upon; and thus the different modes of operation by which the transfixing arrow, dart, and lance were in those early days of surgical science removed from the bodies of the wounded may sometimes be gathered from HOMER'S lucid and minute descriptions. He mentions three different methods at least by which the weapons of war were extracted—viz., first, by evulsion or traction of the weapon backwards, as in the case of MENELAUS ("Iliad," Lib. IV., v. 214); secondly, by protrusion or pushing of the instrument forward, as in the case of DIOMEDES (Lib. V., v. 112); and thirdly, by enlarging the wound and cutting out the weapon, as was the practice of PATROCLUS in the case of EURYPYLUS (Lib. XI., v. 218). In his semi-historical or political romance, the "Cyropædia" (Lib. I., cap. 6, Sec. 15), XENOPHON makes his young and royal hero CYRUS, the founder of the Persian monarchy, speak, among other matters, of the importance of medical officers being attached to armies. "With respect to health" (says CYRUS), "having heard and observed that cities that wish health choose physicians, and that commanders for the sake of their soldiers take physicians, so when I was placed in this command I immediately attended to this point, and I believe that I have men with me that are very skilful in the art of physic."

In the earlier periods of Roman history and Roman warfare the treatment of the military sick and wounded was in all probability intrusted to the casual care of some fellow-soldiers whose tastes and inclinations had led them to pay more than usual care to the rude surgery which existed at the time. As early, however, as the commencement of the Christian era we find CELSUS laying down distinct and in many instances very excellent and practical precepts for the extraction of weapons of war from the bodies of the wounded. But neither in CELSUS nor in any other ancient medical work is there allusion to surgeons or physicians being regularly appointed as army medical officers in the Roman army for the purposes of superintending the treatment of the wounded, or of taking professional care of the soldiers disabled by sickness, whose number in ancient days was, as it now is, much greater than the number of those disabled in fight. We know from the oft-repeated anecdote regarding ARCHIGENES, as told by PLINY, that in the early days of republican Rome the practice of medicine was not encouraged among the inhabitants of the Eternal City. But in the later periods of the empire there was an abundance of native and foreign physicians in

Rome. When the Emperor SEPTIMIUS SEVERUS determined to subdue the whole of Scotland he, about the year A.D. 208, led an army of not less than 80,000 men across the Forth, marched them north, apparently as far as the Moray Firth, and thence returned to York. But though in this course the Roman Emperor nowhere met the enemy in open fight, he is stated to have lost in this single campaign not less than 50,000 of his troops. It is to be expected that common experience and losses such as SEVERUS sustained by disease would have suggested to the Romans the propriety of increasing the strength and success of their armies by having medical men to watch over the health of the soldiers who were fighting in so many different regions around the Roman standards. Some modern discoveries in Great Britain and elsewhere show that such a conjecture is not at variance with truth and that the Roman armies were provided, at all events in the time of the empire, with a medical staff although CELSUS does not happen to allude to the circumstance.

Annotations.

"Ne quid nimis."

THE SHALLOW WELL AND ITS WATER.

NOTWITHSTANDING the steady progress which is being made in most parts of the country in general sanitation the shallow well may still be found to be supplying with drinking water a very considerable proportion of the population and this is more particularly the case in rural and in small urban districts. Of these latter the Stowmarket urban district is a noteworthy example and the facts disclosed by Dr. C. W. Low, the medical officer of health, place a serious onus upon the local district council. Of the 118 wells, which are practically all at present in use, no fewer than 103 showed signs of recent pollution and are therefore, in the opinion of the medical officer of health, unfit for domestic use. The report which contains these very striking facts does not tell us whether the wells in question form, exclusively of rain water, the only supply of drinking water to the people of Stowmarket but it is to be inferred that this is the case. The pollution in the majority of instances appears to be considerable and the variation in the amount of chlorine in the different well waters seems to prove conclusively that the pollution is due to organic matter. In a sense Dr. Low is in an exceptionally fortunate position as regards the wells in his district, since he has pointed out in previous annual reports that "through the faulty construction of the shallow wells in Stowmarket and their dangerous surroundings the water in these wells is liable to pollution, especially after heavy rains, and is therefore in all cases an unsafe, and in many cases a very dangerous, source of supply for domestic purposes." It would, however, be possible for very many medical officers of health to write in similar terms of the shallow wells in their districts but few officers have, we think, been fortunate enough to find practically all such wells actually polluted when the waters have been submitted to chemical examination. Indeed, the Stowmarket experience in this respect stands, we expect, almost, if not quite, by itself, a circumstance which may possibly find explanation in the fact that the waters were examined during an exceptionally dry season. Clearly these wells ought to be closed by virtue of the fact that all of them are dry steened, unprotected from surface pollution, and presumably in dangerous proximity to pervious cesspools, but it is a little difficult to know, assuming that these wells are the only sources of supply, whence a satisfactory supply is to be procured pending the establishment of public works. If, however, there is already a satisfactory public supply there should not, in all the circumstances, be any serious difficulty in persuading all the holders of polluted wells to substitute the public supply for their polluted wells. But it has to be borne in mind that possibly analyses procured specifically for the purpose of taking legal proceedings may not yield such uniformly unsatisfactory results as analyses made during a remarkably dry period. No doubt, however, the wells most obviously liable to pollution would be taken first. What is urgently needed is a modification of the existing laws relating to the closure of wells obviously liable to pollution by the insertion of the words "likely to be so polluted ...... or dangerous to health" into the Public Health Act, 1875. It is a regrettable fact that in many parts of the country eminently unsatisfactory shallow wells are actually being provided at the present time and in only a few districts are any efforts made to induce householders and well-sinkers to provide wells which are properly protected from surrounding pollution. In some rural districts suggestions as to the proper construction of wells have, we believe, been drawn up and circulated but it appears to us that the Local Government Board might well draw up some regulations or recommendations on the subject which would have the effect of gradually doing away with shallow wells which simply invite pollution. Dip-wells and other wells from which water is raised through moveable lids should be properly steened and the walls should be raised above the ground level. In cases where water is raised by means of a pump the mouth of the well should be securely covered and the pump should be some distance from the well. It would be desirable, too, that the suggestions made by Professor Koch should be sometimes acted upon. He proposed that in the case of unsatisfactory shallow wells a pump should be provided and the well itself filled in up to the water level with coarse and fine gravel, there being at least two yards of fine sand above this. By these means any pollution in the neighbourhood of the well would be likely to undergo satisfactory purification before reaching the water level.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY OF LONDON.

AMONG the more permanent memorials of the centenary of the Royal Medical and Chirurgical Society of London is a "Chronicle" written at the request of the President and Council for the centenary festival held this year. The authors are Dr. Norman Moore and Mr. Stephen Paget and they have compiled a most interesting book. Like most other organisations the Royal Medical and Chirurgical Society arose out of the (temporary in this case) disorganisation of a similar and pre-existing society—a society which, we hasten to say, now shows no trace of its youthful disorders. The date of the foundation of the Royal Medical and Chirurgical Society was Wednesday, May 22nd, 1805, and the place the Freemasons' Tavern. The first home of the society was in Verulam-buildings where it remained from 1805 to 1810, then it moved to Lincoln's Inn-fields where, though in different houses, it remained until 1834. Then came the move to Berners-street where the society remained from 1835 to 1889, and finally the society took up its present quarters in Hanover-square in 1890. The book is divided into two parts, the first of which contains the history of the society and the second the names of past presidents with the careers of those who are dead. In the first part, also, are short notes on the proceedings at the meetings, *précis* of interesting papers, and other matters, amongst which last is one of special interest to ourselves—namely, the proposal in 1854 (the date 1852 given on p. 104 is obviously a slip) to exclude THE LANCET and the *Medical Circular* from the library. Altogether the retrospect is of great interest and should be studied not only by the Fellows of the society but by other medical men as well.

THE HYGIENE OF THE LONDON STREETS AND MOTOR TRAFFIC.

PEDESTRIANS in the streets of London are already realising that a gradual and remarkable change in the method of vehicular locomotion is taking place. The change has been more marked by the advent of the motor omnibus which represents probably the weightiest motor vehicle for passengers that has been so far employed The traffic of central London—the Strand, Holborn, Oxford-street, and the City—consists mostly of omnibuses and when these cease to run the streets appear comparatively empty. When, therefore, the horse-drawn omnibus is exchanged for a motor omnibus we may regard the motor traffic as practically established so far as the London streets are concerned. With this change of traffic there must be a change in the degree and kind of the pollution of the streets and of the air, for until the motive force for propelling traffic can be created at a distance and stored, as in the case of electricity, there must always take place some kind of pollution of the air of the streets. The old pollution, that of the excreta and emanations of horses, will give way to the new pollution—the products of perfect and imperfect combustion of the petrol of the motor. We may assume, therefore, that the pollution will increase as regards its purely chemical character and will cease as regards its biological qualities. The impurities arising from the incomplete combustion of fuel are much less likely to be pathogenic than the products of physiological combustion and in this respect the displacement of horse traffic by motor traffic is calculated to effect a sanitary improvement. The streets of London are ever full of dust and the bacteriology of this dust, derived so largely as it is from animal traffic, is appalling and decidedly sufficient to account for a number of pathological conditions in those who come into contact with it. Affections of the nose and throat are very common in the pedestrians of busy streets, though it would seem that those who are constantly exposed to the dust of traffic enjoy some immunity and become, so to speak, hardened. The man fresh from the clean country or sea air experiences an irritable condition of the nose and throat after he has been a little while in the London traffic, especially in dry weather. Similarly, on the return from his holidays the Londoner himself is often attacked in the same way. Will what we have termed the new pollution—that is, the pollution of the motor-car—remove this pathogenic factor of horse-drawn vehicles? It is probable; but only perhaps to give place to a fresh element, active in producing headache, depression, and languor. At any rate, we know that the imperfect combustion of volatile hydrocarbons gives rise to poisonous products and the vapour of the hydrocarbon itself or of petrol when inhaled causes distressing symptoms. In this sense therefore the new pollution of the streets may be worse, hygienically speaking, than the old pollution but we may fairly hope that we have not yet seen the ideal motor and that further improvements will tend to the complete utilisation or burning up of the volatile fuel. At times the trail of motor-cars, and especially of motor omnibuses, in the streets is nauseating with smoke and petrol fumes, and if this is the case when only a fraction of the traffic is motor-propelled what will it be like when the horse has been practically banished? Many of us will wish for the horse again if the methods of combustion are not improved in the direction indicated. But perhaps a new motive agent will be found; indeed, could the obvious difficulties be overcome liquid air would be ideal for the purpose, as then not only would the motor traffic not pollute the air but it would actually provide the streets with a fresh supply.

HYPNOTISED WITNESSES.

THE medico-legal relations involved by the practice of hypnotism have several times been discussed in the courts of the United States of America. Quite recently in the case The State *v.* Exum it has been decided that the statement by a witness on cross-examination that she had been thrice hypnotised by the prisoner is admissible as affecting the credibility of her evidence. It was not alleged in this case that the witness was actually in the hypnotic state, for then she would have been held quite incompetent to offer testimony. What counsel sought to prove was that she was then and there the subject of a post-hypnotic suggestion. It is admitted that proof of such a mental condition must be very difficult; the judge, whose function it is to decide the competency of a witness, would have to consider many pertinent facts. Once, however, the state of post-hypnotic suggestion is established there can be little doubt that a witness so obsessed should be ruled unable to testify on behalf of the party responsible for that condition. It must be remembered that possible actions of the victims of *suggestions à longue échéance* are still hotly debated in the French schools of hypnotism: at the Salpêtrière they hold that the educated moral sense is not annulled by a criminal suggestion; at Nancy they have several practical if reprehensible illustrations that when hypnotised the mind does not revolt at a suggestion which leads practically to the performance of a misdemeanour or a crime.

RECURRING PHLEBITIS OF OBSCURE ORIGIN.

IN the *Johns Hopkins Hospital Bulletin* for June Dr. J. B. Briggs has described a form of phlebitis affecting the veins of the extremities which occurs without apparent cause and has received little attention from systematic writers. The cases are rare and show many striking features in common, so that they form a well-defined group. They are characterised by a progressive and relapsing course. They resemble in their main features those described by Sir James Paget and others as gouty phlebitis. But in Dr. Briggs's cases no evidence whatever of gout could be elicited. The following is an example. A healthy student, aged 23 years, who gave no history of gout or rheumatism, awoke one morning in May, 1901, with a sensation of stiffness at the inner side of the left ankle. The sensation disappeared during the day but recurred next morning with increased severity. Examination on the fourth day showed that the left internal saphenous vein formed a firm and tender cord in the lower part of its course. There were in the malleolar region slight superficial redness and œdema. The symptoms subsided in about a fortnight and a tough cord three centimetres in length remained. Careful examination failed to show any infectious process and the general health was excellent. Early in July the patient awoke one morning with sharp pain in the left leg and found a thrombotic cord continuous with the first one extending about six inches above it in the course of the internal saphenous vein. There were considerable œdema of the inner part of the leg and some redness and heat. Tenderness was extreme. Prolonged immersion in a stream of cold water was performed several times a day which relieved the pain and enabled the patient to walk about. After two weeks the symptoms had disappeared and there remained only the firm cord of the occluded vein. The general health was unimpaired even when the pain was greatest, there was never any pyrexia, and the leucocytes were below 8000 per cubic millimetre. A characteristic feature was that the pain was diminished by exercise and increased by rest. Thus on awaking in the morning it was always intense. On walking about it diminished and in the afternoon the patient could play tennis. In August there was another attack affecting the vein as high as the knee; in October one occluding the saphena vein to a point five centimetres above the knee; and in December one continuing the process nearly to Poupart's ligament. The attacks were all precisely similar; they began during the night and the thrombosis never extended beyond the point which it reached at the beginning of the attack. Œdema was never marked and appeared only on the inner part of the leg corresponding to the thrombosed vein. It is noteworthy that embolism did not occur, although the patient walked about even when the inflammation was at its height. Three years after the last attack the obliterated internal saphenous vein could be traced as a fibrous cord up to the middle of the thigh. In April, 1905, another attack occurred. Dr. Briggs describes two other cases and cites five similar ones. In two cases the arms were affected but these cases differed from the others in the fact that there were no relapses. Dr. Briggs does not agree with the view of some writers that this phlebitis is a manifestation of gout, as there was no evidence of this disease. He suggests that it may be due to a sclerotic change in the veins analogous to arterio-sclerosis.

THE UNRESTRICTED SALE OF DANGEROUS DRUGS.

AN inquiry was held recently in Guernsey into the circumstances attending the death of a lady named Bird, when the following facts were elicited, to which attention may well be drawn. Mrs. Bird had been ill for some time and had been treated by Dr. E. V. Gibson who regarded her as on the road to recovery; in fact, she was, in the words of a nurse who had left her on May 11th, nearly convalescent. She had, under the directions of Dr. Gibson, taken veronal but he had not ordered her any for some days previously to her death. It was proved, however, by her letter giving the order that she wrote to Messrs. John Barker and Co. of Kensington for veronal and received from them on a Thursday morning a packet containing an ounce of the drug. On the following Saturday a nurse who was then attending her found her trying to get into bed, when she explained her position by saying that she had fallen out of it and after this she was observed to be drowsy. On the following day her condition attracted the attention of Dr. Gibson who examined her and ordered a search which resulted in the finding of the packet containing veronal. He then did all that was possible to avert death which, however, took place on the following Tuesday. It was shown from the amount remaining that between Thursday and Saturday, probably on Saturday morning, the unfortunate lady had taken about half an ounce of veronal. Not unnaturally Dr. Gibson called attention in his evidence to the fact that so large a quantity of veronal as an ounce, invoiced at 6*s.* 6*d.*, could be transmitted without restriction of any kind to anyone sending an order by post, and the court, very properly, adjourned the inquiry in order that further particulars with regard to the purchase might be proved. This resulted in the production of the letter written by the deceased, together with evidence by His Majesty's Comptroller, who obtained it for the purpose of the inquiry, that he had also received a box of veronal of the kind sent to Mrs. Bird. The important point with regard to this, and one not less serious than the free and unrestricted sale of so large a quantity of the drug, consisted in the fact that the box was stated not to have been accompanied by any instructions or warning with regard to its contents. It is hardly necessary to point out how dangerous the sale of medicinal compounds may be without strict directions as to dosage and it must also be remembered that what may happen in such circumstances is that a medical man may order a medicine to be made up in a mild form suitable to the case of a particular patient and may direct a certain bulk of it to be taken. The patient, however, who happens to have learnt in general terms the description of what has been prescribed may purchase for himself unknowingly a much stronger preparation. If he does so the result of taking the same quantity in bulk that he swallowed before with beneficial result is likely to be serious. We should recommend druggists to exercise discretion in the sale of drugs an overdose of which is likely to lead to fatal results and to refrain from selling them except in accordance with a medical man's prescription. If they decline to do this they should indicate a dose, taking good care to fix it on the safe side; otherwise they must not be surprised to find their names mentioned at inquests and disapproval of their methods expressed. In the case of Mrs. Bird a verdict of "Death by misadventure" was returned, the jury no doubt attaching weight to the omission of directions as to dosage proved before them. Dr. Gibson did good service in calling attention to the matter.

ACETONURIA IN SURGICAL CASES.

ACETONURIA is well known as one of the phenomena of diabetic coma. It has also been observed under a number of other conditions of which the best known is the administration of an anæsthetic. Recently we called attention to a series of cases in the Boston Children's Hospital in which death occurred in peculiar circumstances and acetonuria was present.[1] In most of them an operation had been performed under anæsthesia. The condition in which acetone and diacetic acid appear in the urine has been described as acid auto-intoxication but our knowledge of it is most imperfect. The *Boston Medical and Surgical Journal* of June 29th contains an important contribution to the subject by Dr. J. C. Hubbard. He shows that, like many other conditions described as rare, acetonuria is considered so only because it has not been looked for. His attention was drawn to the subject by the series of cases referred to above and he examined the urine of a number of patients on admission to the Boston City Hospital. The urine of 110 patients was examined for acetone and diacetic acid, that of 35 for acetone alone, and that of five for diacetic acid alone Acetone was found in nine cases, in four of which it was associated with diacetic acid. The following is an outline of the cases. 1. A girl, aged 16 years, had chronic tuberculous adenitis of the neck. The glands were dissected out and the wounds healed. 2. A boy, aged seven years, was admitted with symptoms of concussion of the brain on the day after he was thrown on his head. He was discharged on the following day. 3. A woman, aged 50 years, had an appendicular abscess which was successfully drained. 4. A man, aged 26 years, was admitted with chronic appendicitis and inguinal hernia. An interval operation for appendicitis and Bassini's operation were successfully performed. 5. A boy, aged 10 years, was admitted with symptoms of concussion after falling from a wagon on his head. There was slight mental confusion for 12 hours. 6. A girl, aged eight years, sustained fractures of the humerus and clavicle and vomited much fluid containing blood. 7. A man sustained fracture of the pelvis. 8. A woman, aged 21 years, had symptoms suggesting salpingitis. 9. A woman, aged 21 years, had fracture of both bones of the leg. In none of these cases did the urine contain albumin or sugar. All ran an ordinary course. Thus acetonuria was found in nine out of 135 surgical cases and it must be a much more frequent condition than is generally supposed. In another series composed of five cases the urine was found to contain acetone or diacetic acid on being examined to furnish an explanation for some irregularity in the course of convalescence. The following are two examples: 1. A boy, aged four years, had a fracture of the femur which was set on April 21st, 1904. An attack of measles began on June 18th. On the 20th he was drowsy and there had been an odour of acetone from the breath for five or six days. On May 20th the urine did not contain acetone or diacetic acid; on June 19th both were present. 2. A girl, aged 11 years, had her appendix removed on May 11th. On the 23rd a secondary abscess discharged. On June 17th the urine contained no albumin, sugar, acetone, or diacetic acid. Vomiting began and on June 30th the urine contained a trace of albumin, hyaline and fine granular casts, blood, numerous polynuclear leucocytes, acetone, and diacetic acid. In these five cases the symptoms yielded readily to the administration of bicarbonate of sodium. What the course would have been had the acetonuria not been recognised cannot be said. In two other cases acetonuria was found and death ensued.. 1. A boy, aged nine years, was operated on for appendicitis on May 16th, 1904. The appendix, which was injected and swollen, was removed. Vomiting occurred after the operation and on the following days. On the 18th there was a sweet odour from the breath. On the 28th the temperature was irregularly elevated, nothing was retained by the stomach, and death occurred. Acetone and diacetic acid were found in the urine on the 19th and persisted until death. A girl, aged 12 years, had acute osteomyelitis of the lower end of the right femur. An operation was performed on April 4th, 1904, and pus was found in the medullary cavity. Abscesses developed in various bones which were trephined as follows: April 6th, right femur; 10th, left femur; and 13th, left fibula. On the 25th an abscess of the right parotid was opened. After this convalescence seemed to progress until vomiting began and acetonuria was found. The vomiting persisted until death which occurred on May 20th. In none of the cases was there any glycosuria. Dr. Hubbard concludes that three forms of acetonuria may be distinguished: one without symptoms in which the prognosis is not affected; a second with moderate symptoms and of only slight importance; and a third with severe symptoms and a grave prognosis. Acetonuria occurs most frequently in the young. It is noteworthy that in the two fatal cases the ages were only nine and 12 years. The most prominent symptoms observed in the recorded cases were vomiting, apathy, and the odour of acetone in the breath. The treatment usually adopted was the administration of bicarbonate of sodium in 30-grain doses thrice daily or every four hours.

---

[1] THE LANCET, Sept. 17th, 1904, p. 846.

THE SOCIETY OF CHEMICAL INDUSTRY.

DURING the past week a convention was held in London which represents the twenty-third annual meeting of the Society of Chemical Industry and the first international meeting held in this country. The election of Mr. William H. Nichols, M.S., LL.D., D.Sc., a distinguished manufacturing chemist of New York, to the office of President attracted a number of American guests. Amongst many entertainments provided for the visitors was a day at the Wellcome Club and Institute at Dartford, Kent, the meeting serving also to commemorate a quarter of a century's work of the firm of Messrs. Burroughs, Wellcome, and Co. The visitors included a number of distinguished workers in chemical science and in chemical industries throughout the British Empire and America, and the medical profession was also largely represented. The main object of the society is to encourage the application of chemical science to industry and during the 23 years of its existence the progress which has been made in this direction has been very satisfactory. Its extension happily threatens to destroy root and branch the "rule of thumb" methods of antiquated manufacturers. The position which the society takes is that pure science must be the handmaiden of industry if progress is to be made and if our position as an industrial nation is to advance and not to fall back. Money must be spent in training men for the work of special research bearing upon the nature of the industry pursued and trained men of science should in future occupy something more than a mere academic position and should fill the post of adviser, investigator, and controller in the various manufactures of the country. An excellent example has been set in this direction by Messrs. Burroughs and Wellcome who have instituted in connexion with their manufactures admirably equipped chemical and physiological research laboratories. Apart altogether from the decided advantage which the possession of research laboratories gives to the preparation and manufacture of medical and pharmaceutical preparations results are gained also which are from time to time communicated to the learned societies and which are calculated to spread a more exact knowledge of the pharmacology of drugs. Professor H. E. Armstrong, F.R.S., who has pleaded so eloquently for the application of science to industry in this country, in a speech made at the meeting paid a warm tribute to Mr. H. S. Wellcome for his enterprise. It was evident also to the visitors on Saturday that the latter gentleman does not forget that success depends on a harmonious relationship subsisting between the employer and the employé. Every consideration had been extended to the employés as regards their comfort and well-being, as evidenced in the foundation of the club and institute and the spacious and pretty grounds provided for their recreation.

LONDON'S FOREIGN MEAT-SUPPLY.

THE existence of the huge organisations controlled by the Corporation of London in connexion with the importation of live cattle, sheep and oxen, for the supply of the London markets was emphasised recently by a visit of inspection to Deptford made by the Markets Committee which is responsible for the work, and at this visit one of our commissioners was privileged to be present. The dockyard and abattoirs, where the cattle are slaughtered within ten days from the date of landing, are situated in a remote, but extremely picturesque, corner of Deptford. The abattoirs were erected some few years ago upon lines embracing the best features of continental models then extant and, it is almost needless to say, are kept scrupulously clean. The large cattle-boats now running chiefly from America and Canada (the Argentine boats having ceased within the last two years) anchor off Gravesend, seldom coming as far as Deptford owing to the difficulties of navigation. The cattle are transhipped to boats kept for the purpose belonging to the corporation and so expert have the crews become in the work that 500 or 600 head of cattle are transferred from one boat to another in an hour, while the same number can be landed from the boat at Deptford in 50 minutes. The boats have two lower decks divided into compartments fitted with light- and air-shafts and, in addition, possess an electric installation. These cattle decks are lime-whited throughout after each trip. In the centre of the boat is the cattle ladder or gangway by which the beasts reach the lower deck after the reluctance of the leader to descend the ladder has been over-ruled, the others following without much hesitation. Notwithstanding the apparent difficulty attending transhipment accidents to the men employed or to the animals are rare. There is one point, it seems to us, which admits of improvement. The cattle decks might be formed of some impervious material such as asphalt (corrugated) draining into a sump or portable tank. This would permit of these decks being flushed with a hose and would prevent the possibility of the bilge becoming contaminated. The beasts on arrival are duly examined by the veterinary officer in charge. On the occasion of the recent inspection the members of the committee of the three markets—viz., the Central, the Caledonian, and Leadenhall—attended by various officials, including the port sanitary officer, dispersed and inspected the vessel in sections, afterwards meeting in committee on one of the boats to compare notes.

MEDICAL EXCURSIONS FOR STUDENTS OF MEDICINE.

WE are enabled this week to lay before our readers some further information concerning the "Voyages Médicaux" organised by M. E. Bazot. Names should be sent to him at the Service Annexe de l'Œuvre des Voyages Médicaux, 1, Rue de l'Echelle, Paris, as soon as possible, the latest day for their reception being August 2nd, but subscriptions need not be sent in before that date. The money may be sent by money order. The committee of the Association Corporative des Étudiants en Médecine is taking all the measures necessary for the welcome of British fellow students and has organised an informal and friendly reception which will be held on the evening of the day of arrival at Paris. Besides this reception another one is offered by the administrative committee of the Voyages Médicaux. Time, however, is short and as we said last week we greatly fear that but little can be done this summer.

A CASE OF ANGINA PECTORIS WITH UNUSUAL SYMPTOMS.

WE have received a reprint of a paper published in the spring number of *Brain* by Dr. G. A. Gibson of Edinburgh on Some Hitherto Undescribed Symptoms in Angina Pectoris. The case was most carefully observed and presents some features of interest from which Dr. Gibson deduces certain noteworthy conclusions relative to the innervation of the heart. The patient was a strongly built labourer, 45 years of age, with a healthy florid complexion, and was admitted to the Royal Infirmary complaining of pain in the chest and left arm which dated from five weeks before admission and was associated with some breathlessness on exertion. There was no history of alcoholism and the patient's home conditions were healthy and comfortable but his work was heavy. The pain after a time began to show paroxysmal exacerbations, during which the face became pale and the arteries small and hard. The cardiac impulse was situated in the left nipple line four and a half inches from the mid-line of the sternum; there was some enlargement of the area of cardiac dulness. The heart sounds were clear but the aortic second sound was much accentuated. All the superficial arteries were thick and tortuous and the arterial pressure, estimated by Hill and Barnard's sphygmometer, was found to vary between 160 and 170 millimetres of mercury. The unusual features of the case consisted chiefly in the character and distribution of the sensory changes. There was constant pain over the back on the left side as far down as the ninth intercostal space and extending up to the back of the neck, over the clavicle, and down the front of the chest as far as the eighth space. It involved the whole of the shoulder and extended down the outer aspect of the arm and forearm so as to reach the thumb, index and middle fingers. Over the greater part of this area there was hyperæsthesia to all forms of stimuli except over the radial portion of the hand where there was absolute anæsthesia bounded by a small zone of analgesia without anæsthesia. The sterno-mastoid, trapezius, pectoralis, deltoid, biceps, and supinator muscles of the left arm were tender and there was great weakness of the left hand. All these muscles showed a condition of increased electrical excitability when tested by faradism and galvanism. The left eye was more prominent than the right and the left pupil was larger than its fellow. The diagnosis made was that of early arterial sclerosis, probably implicating the coronary arteries and associated with some interstitial changes in the myocardium. The changes in the muscles were attributed to afferent impulses and were regarded as analogous to those seen in arthritic muscular atrophy. The sensory changes found their explanation on Head's well-known law of referred pain. From a consideration of the symptoms Dr. Gibson regards them as confirming conclusions which he has published in his Morison lectures as to afferent impulses from the heart, that they travel by the inferior cardiac nerve to the inferior cervical ganglion of the sympathetic and thence by the grey rami to the seventh and eighth segments of the spinal cord.

RE-AFFORESTING THE APENNINES.

ONE of our correspondents in Italy writes:—"The function of forest growth in maintaining the balance between moist exhalation and beneficent rainfall was nowhere more strikingly illustrated than in Italy, whose 'waving woods' and exuberant soil were among her 'praises' commemorated by Virgil. For centuries, however, persistent tree-felling uncompensated by collateral tree-planting has robbed her of that enviable distinction, and so we find denuded hillsides annually visited by prolonged drought and torrential downpour with progressive injury of agricultural and industrial interests till, all too tardily, the legislature has had to intervene with such remedies as it can devise. Mainly under medical inspiration and initiative societies 'Pro Montibus et Silvis' have cropped up in the present generation and the 'Legge Forestale' of Baccelli marked a step to be followed by others towards the 'consummation devoutly to be wished'—the reclothing of the naked uplands and the return to the normal interchange of gentle evaporation and fertilising shower. Just before Parliament rose for the summer one of its ablest members, Dr. Antonio Celli, professor of hygiene in the Roman University, put a series of questions to the Ministers of Agriculture and Public Works tending to stimulate the 'ricostituzione idraulica forestale dell' Apennino,' but received answers so unsatisfactory that he gave notice of a motion to be tabled at the next meeting of the legislature. It is to be hoped that Dr. Celli's interpellation will bear fruit, there being few reforms so urgent as that contemplated by his motion if Italy is to retain her chief industry—the vine and olive culture—at its normal standard and is not to lose her 'amenity' so seriously compromised in the year now passing."

CONVALESCENT HOMES ASSOCIATION.

THE constitution and rules of this new association were settled at a recent meeting of the council. The object of the association is to coördinate the work of public convalescent homes receiving London convalescent patients, whether from their own homes or from the metropolitan hospitals; to obtain and to disseminate information on the needs of London in respect of convalescent relief and on all other matters of interest or importance to the members of the association; to advise them on equipment, management, and maintenance; to watch over and to protect their rights and interests as they may be affected by legislation or otherwise; to serve as a means of communication and to assist coöperation between convalescent homes and hospitals and other public institutions; and generally to take such action as may be desirable in any matter in which convalescent homes are interested. The council, which is to be the governing body of the association, is to consist of a certain number of representatives according to the number of beds in each convalescent home, representatives of the metropolitan hospitals, and a representative of each of the following public bodies: the Metropolitan Hospital Sunday Fund, the Hospital Saturday Fund, the Central Hospital Council, the Charity Organisation Society, and the Invalid Children's Aid Association. An executive committee will be a committee of the council and will transact the main business of the association. Each convalescent home becoming a member of the association is to contribute a small subscription, the amount depending on the number of beds possessed by the home. All institutions and individuals, not being already subscribers, applying for information or otherwise making use of the association are to pay a minimum fee of 1*s.* for each application. The President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England are to be *ex officio* vice-presidents of the association. We think that there are very evident uses for such a body as the Convalescent Homes Association and we are glad to see that it is getting into working order. The starting of such an association is an exceedingly troublesome matter, as there are many difficulties to be overcome. Some of the convalescent homes see no need for the new body and fear to do anything which may sacrifice any part of their independence. They need have no such fears, for the association should prove of the greatest assistance to the individual homes and should tend to coördinate them so as to increase greatly their influence and value. We shall look forward with interest to the work of the Convalescent Homes Association.

THE first congress of the International Society of Surgery will be held in Brussels in September under the patronage of His Majesty the King of the Belgians. The congress will be in session from Monday, Sept. 18th, to the following Saturday inclusive, under the presidency of Dr. Theodor Kocher, professor of surgery in the University of Bern. All further information can be obtained from Mr. Reginald Harrison, F.R.C.S., the British delegate, 6, Lower Berkeley-street, London, W.

THE French Académie de Médecine has awarded, through the Minister of the Interior, a silver medal to Dr. Alan B Green, bacteriologist in charge of the vaccine lymph department of the Lister Institute of Preventive Medicine, for his work on "Vaccine," published in the Proceedings of the Royal Society and in the Report of the Medical Officer to the Local Government Board.

THE first International Congress of Physical Therapy will be held at Liége from August 12th to 15th, under the patronage of the Belgian Government and a number of eminent medical men and men of science of all nations. Communications should be addressed to the secretary of the English committee, Mr. W. Deane Butcher, M.R.C.S., Holyrood, Ealing, W.

Professor D. I. Mendeléeff, the distinguished professor of chemistry at the University of St. Petersburg, completed the fiftieth year of his public professional services on June 13th and a celebration of his half a century in Government service will take place on August 30th.

UNIVERSITY OF OXFORD.—An examination for the Radcliffe Travelling Fellowship of the annual value of £200, tenable for three years, will be held in Hilary term, 1906.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 21, 1827.

THE RESPECTABILITY OF THE COLLEGE OF SURGEONS, AND ITS USEFULNESS IN THE SUPPRESSION OF QUACKERY.

IT has often been observed, that visitors can readily detect abuses, when those who are living within the sphere of their operations are blind to their turpitude. It would appear, from the indifference manifested by some, that the march of improvement in the legislation of corporate bodies, had been so rapid as to leave little to reform; and that our College of Surgeons had really accomplished all that it was designed to do; that it had become the sole protector of "sound chirurgical knowledge;" and that it discountenanced and suppressed everything which had a "contrary tendency."

On looking over a work recently written by a German physician, (Dr. Casper,) describing the state of medicine in England and France, we felt, as we have no doubt others will feel, ashamed of the testimony he has given to his countrymen; but at the same time, being convicted of its truth, we were ashamed that we belonged to a body permitting such dissolute and unrestrained quackery. Having spoken of the excessive disproportion of practitioners to the requirements of the population, he says,

"I was shown an address-book of about the thickness of my two fingers, containing the names of those only who were inscribed as Members of the 'Royal College of Surgeons!' It was by no means rare to find on the house doors, the names of two or more surgeons, with the appendix of a Co., as 'Philips, Sumpton, and Company, surgeons, &c.' My readers will probably not be less surprised than myself at these ostentatious displays, and will be disposed to inquire, as I did, what they could mean; whether the gentlemen treated their patients conjointly; whether it was so contrived that one of the Co. should always be at home, in case of accidents, and so forth? At length the riddle was solved. The whole concern was only a branch of the London quackery. Among the common sort of English, in whom a commercial spirit is not less innate than that of 'Freedom,' the word 'Company' is considered a good assurance for the solidity of a firm; and, by analogy of reasoning, two or more surgeons are supposed to possess more skill when practising in 'Company,' than if alone.

"In London, as in Paris, the punctum saliens of medical quackery is *syphilis*, and here again we find 'Consultation Houses,' and the usual nostrums. But it would offend the vision of the modest and bashful Englishman if such things should be announced on hand-bills at the corners of streets; the quacks in London have therefore invented a different plan to disseminate their boasted skill among the multitude: they employ men to distribute little advertisements to the foot passengers, who at their leisure may read the disgusting contents. Some of them have some enticing motto prefixed, as 'Speedy cure on moderate terms!' others are said to be 'For the benefit of the army, navy, and the public in general!!' I was informed that there were certain 'Medical establishments where men are rescued from perilous diseases without the use of mercury, which has proved the death of thousands, in the hands of *ignorant quacks!*'

"Just in the same style hundreds of similar forms of deceiving the public practised in the capital of a country, which may be proud to call a Hunter, an Abernethy, a Lawrence, a Bell, and a Cooper her sons. According to the pretentions of the advertisers, what wonders are not 'Leake's justly famous pill' capable of accomplishing? Prepared and sold, as the dirty paper announces, by the Taylors, in a street leading to Blackfriars-bridge, who say they are *Members* of the *Royal College of Surgeons!*" Dr. Casper then goes on to sneer at the contents of the papers, detailing the marvellous efficacy of these pills of "immortal and universal fame," and concludes his remarks by congratulating his countrymen on their being free from such disgrace. "Luckily," says he, "Germany can look down upon and laugh at these disgraceful fooleries of her *enlightened* neighbours!!"

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH, 1505-1905.

THE Royal College of Surgeons of Edinburgh, which has during the present week been commemorating with suitable ceremonial and social entertainment the 400th anniversary of its incorporation, is the oldest surgical or medical corporation in the United Kingdom. The Royal College of Physicians of London, the next in order of age, dates its official birth 13 years later, in 1518. All the other colleges date from a century to three centuries later. There is thus a very special interest attached to the celebration of the fourth centenary of this College, and the readers of THE LANCET will be interested in a sketch, brief though it may be, of its history during the eventful 400 years of its existence.

The precise date of the birth of the College as a corporate body is July 1st, 1505, a date which places it eight years before the battle of Flodden, at a time when Edinburgh was a walled city and when Scotland had not passed through the turmoil of the Reformation.

The charter was granted by the town council of Edinburgh as the result of the presentation of a "Bill of Supplication" to that body by "the kirkmaister and brethren" of the "Surregeanis and Barbouris" within the Burgh of Edinburgh. The charter, or "Seill of Cause," appears to have been granted readily. The main supplication of the surgeons and barbers was that they should be incorporated as one of the burgh crafts, so that they must have formed by that date a considerable body, associated in some way and acting together with some measure of *esprit de corps*. They, however, not only sought incorporation as a craft but in their petition applied for power to admit others into their craft after examination. The inclusion in their petition of the request for an examination to be held by the masters of the craft has been much dwelt upon by some of the historians of the College not only as a praiseworthy arrangement but as a novel and unique condition at the time. The examination, however, was only a means of securing that the monopoly of practising the craft within the burgh should be in the hands of competent men. This is brought out in the words of the petition "thatt na maner of persoun occupie nor use any poyntis of oure saidis craftis of surregerie or barbour craft within this burgh bott gif he be first frieman and burges of the samyn and thatt he be worthy and expert in all the poyntis belongand the saidis craftis deligentlie and avysitlie examinit and admittit be the maisteris of the said craft." That the examination was intended to be a test of such knowledge as the candidate could acquire from the masters of the craft in Edinburgh is evident from the wording of the petition, for it is there specified that "he knaw anatomea nature and complexioun of every member in manis-bodie and in lykewayes he knaw all the vaynis of the same thatt he may mak flewbothomea in dew tyme and als thatt he knaw in quhilk member the signe hes domination for the tyme for every man aucht to knaw the nature and substance of every thing thatt he wirkis or ellis he is negligent." It is thus quite evident that what we now call "professional knowledge" was required of the candidates and that this is to be regarded as the earliest beginning of the system of examination still guarding the portals to the practice of surgery. That those early masters of the craft valued in some degree a knowledge of anatomy is shown by the further request in their petition "that we may have anis in the yeir ane condampnit man efter he be deid to mak anatomea of quhairthrow we may haif experience, ilk one to instruct uthers." And there is added the promise, "And we sall do suffrage for the soule."

SIR PATRICK HERON WATSON,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH

While this examination was necessary before admission to the craft it was preceded by a period of apprenticeship to one of the masters extending over a period of five years. Even at the early date of which we write there was what may be taken as the equivalent of the present preliminary examination, for no master was allowed to take an apprentice unless the proposed apprentice could "baith wryte and reid." The charter thus granted by the civic authorities was confirmed in the following year by Royal authority.

For three quarters of a century there appear to be no records of the doings of the newly incorporated craft, but by the year 1589, according to Dr. John Gairdner's investigations, a practice had sprung up of separating in some measure the barbers from the surgeons. By that date it appears that "single" barbers were admitted to the corporation, but not to its full freedom, and were forbidden to practise any "point of chirurgie under pain of tinsell of their fredome."

In the time of the Protectorate there existed outside the surgeons and barbers craft a body both of unincorporated physicians and unincorporated apothecaries who threatened to invade the domain which the incorporated craft claimed as their own. There seems to have been great alarm aroused by the aggressive action of those two bodies but the alarm was allayed by the apothecaries abandoning their allies the physicians and coming to terms with the surgeons. The outcome of this was that a "brotherhood of apothecaries and chirurgeon-apothecaries" was constituted. The town council Act establishing the brotherhood bears date Feb. 25th, 1657, and was confirmed by Parliament on August 22nd, 1670. Another Act in 1695 constituted the surgeons "chirurgions and chirurgion apothecaries."

This Act of 1695 was the Parliamentary ratification of a Royal grant received from William and Mary the previous year. It made very important concessions, for whereas by the first charter the privileges of the surgeons and barbers were confined within the city walls this Act empowered the combined surgeons and apothecaries to examine all who practised anatomy, surgery, and pharmacy within the greatly extended bounds of the three Lothians and the counties of Peebles, Selkirk, Roxburgh, Berwick, and Fife.

The year 1694 is a memorable one because of other important developments, for at this date it is clear that the idea of a medical school had definitely appeared. An active member of the incorporation, by name Alexander Monteith, applied individually to the town council for a grant of dead bodies for the purpose of dissection. This petition was granted and also a room in which to make the dissections. The regular apprentices of the surgeons were to be admitted to the dissections at half fee. Following immediately upon the granting of this personal application the incorporation made a like request and was equally successful in having it granted. An important condition was attached to the grant to the surgeons—namely, "that the petitioners shall, before the terme of Michallmes 1697 years, build, repaire, and have in readiness ane anatomicall theatre, where they shall once a year (a subject offering) have ane public anatomicall dissection, as much as can be showen upon one body."

Monteith in the action which he took was prompted by, or at all events associated with, Dr. Archibald Pitcairn who held the nominal office of professor of practice of physic in the University and had recently returned from Leyden imbued with the idea of seeing a school established in Edinburgh. The action of these two men must be regarded as having been the means of initiating a definite school of anatomy in Edinburgh. In December, 1697, the surgeons' anatomical theatre was reported to the town council as completed and the council confirmed its grant of 1694 already mentioned.

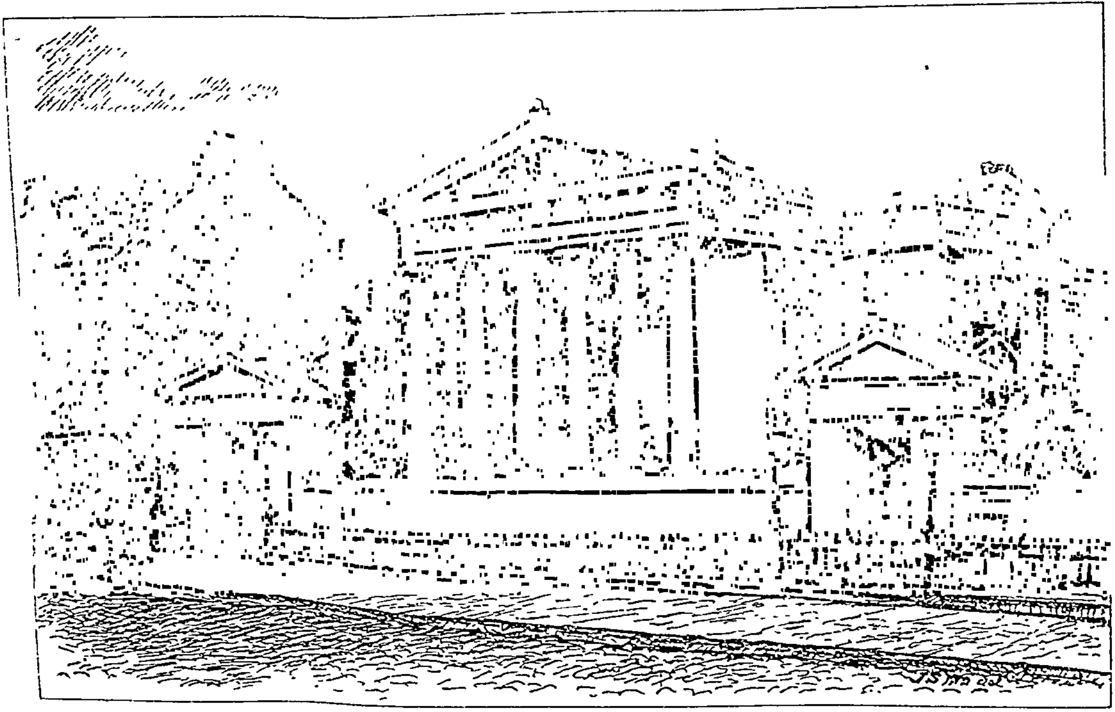
Old Surgeons' Hall from the north, 1697 (from a drawing by Paul Sandby). The figures are from Kay's portraits.

FIG. 2.



Royal College of Surgeons of Edinburgh, 1905 (from a pen-and ink drawing by J. Smith, M D.). Reproduced with the kind permission of the artist.

The surgeons further appointed a committee to arrange "the methods of the public dissections and the operators." The "operators" were those selected to give the formal course of anatomical instruction and an interesting minute indicates a course extending over ten days, each day being taken by a different "operator."

A new order of things was begun in the year 1705, 200 years after the date of the first charter, by the introduction of a system which doubtless indicated that anatomical and surgical knowledge was advancing too rapidly to be dealt with in the primitive fashion described. In this year the surgeons intrusted the entire duty of teaching to *one* of their members, while the town council conferred upon the same surgeon the appointment of professor of anatomy in the University together with a salary of £15 per annum. For the next 15 years this dual appointment was held by

Robert Elliot, Adam Drummond, and John McGill. In 1720 Drummond and McGill, who had been joint teachers, resigned in favour of Alexander Monro. Up to this time, owing to the close and friendly relations subsisting between the town council and the Incorporation of Surgeons and to the fact that the town council appointed the professors in the University, the arrangement indicated above was evidently carried on to the satisfaction of all concerned.

Following the appointment of Alexander Monro medical education rapidly advanced. Although Monro was only 22 years of age when appointed lecturer on anatomy, he had been under the guidance of his father carefully prepared by study, both in Britain and on the continent, for the post he was called to occupy. He gathered round him at the surgeons' theatre four members of the College of Physicians (established by Royal Charter in the year 1681) who taught the theory and practice of medicine and chemistry. Five years after Monro's appointment he, for reasons which need not be dwelt upon, applied to the town council to be provided with room in the University in order to teach there. This request was granted and soon afterwards his four colleagues at the surgeons' theatre applied to be made professors in the University, a request which was also granted. This was practically the beginning of the medical school of the University.

In the meantime other changes were steadily taking place in the older incorporation. After the union of the surgeons and apothecaries the surgeons drifted apart from their brother craftsmen the barbers, although they retained their former rights as barbers and surgeons. The barbers, as has been already stated, had been for some time admitted to the craft without enjoying the full privileges of barber surgeons; in fact, on their admission they bound themselves not to practise surgery. It was not, however, until 1722 that a definite and formal separation was effected on terms mutually arranged and thereafter accepted and approved by the Court of Session. One of the curious terms in this dissolution of co-partnery was the transference to the barbers of the right to make *aqua vitæ*. This right had been one of the privileges granted to the barber-surgeons by their 1505 Charter, so it was at this time lost to the surgeons. The giving of the privilege to the barbers was regarded as compensation to them for the severance of their surgical connexion. It is of interest to note that a similar separation of the barbers and surgeons in London was effected in 1745.

The year 1778 was signalised by the granting of a new charter by which the Incorporation of Surgeons was raised to the dignity of a Royal College with the designation, "The Royal College of Surgeons of the City of Edinburgh." This charter gave the College a national position, while it did not dissolve its connexion with the civic authorities. The origin of this connexion has been indicated in the foregoing account of the origin of the barber-surgeons' craft. The civic authorities, who had granted the charter of incorporation, continued to have an important voice in the affairs of the College and even had control over the choice of the president. For many years there appears to have been little, if any, friction between the civic authorities and the College or the University, in both of which bodies they held the patronage. In the early part of the nineteenth century, however, the town council exercised its right by excluding from the presidential chair the nominee of the College and this because his politics were not acceptable. In 1833 after much striving, this connexion between the civic authorities and the College was finally severed. The town council could no longer dictate to the College and the College president was no longer required to be a member of the town council, which hitherto he had been.

Even after this separation the surgeons continued to be one of the city incorporations. Indeed, it was not until the comparatively recent date of 1851 that by Act and charter all trace of the civic character of the Royal College was swept away and its position as a national college was secured beyond dispute.

It is of interest to inquire how the College has been housed from the time of its incorporation down to the present time. In the earliest days the meetings of the craftsmen were held in the house of the "deacon," as their chairman or president was then designated. In a very short time, however, they are found renting premises to serve as a special meeting place and paying £40 a year as rent. In 1669 they built for themselves a "convening house," which was altered, added to, and, in part at least, rebuilt in 1697. The Surgeons' Hall of that date is represented in the accompanying illustration (Fig. 1). This building was erected within the south-east angle of the city wall on ground originally belonging to the Dominican Friars and overlooking what is still called "The Pleasance." Other buildings were in process of time added, the whole forming three sides of a square and for many years known as Surgeons'-square. The old "Surgeons' Hall" is properly regarded as the birthplace and the nursery of the Edinburgh Medical School. This venerable building with its curious historical associations was superseded in 1832 by the handsome building represented in another illustration (Fig. 2). The Surgeons' Hall of to-day was designed by W. H. Playfair. It contains a large and valuable museum, the gathering of generations of anatomists and surgeons, including the collections of Bell, Wilson, and Barclay. On the ground floor is the large hall in which the meetings of the College are held, also library, writing, and committee rooms. Some of these rooms are fitted with the oak panelling taken from the older hall, while the valuable portraits belonging to the College adorn their walls. The lecture rooms attached to the College are not seen in the accompanying illustration as they are situated behind the main building.

The relations of the surgeons to medical teaching in Edinburgh are deserving of some special notice. It has already been recounted how the Incorporation of Surgeons came to be the parent of the Medical School in the University by the transference of the lecturers from the one to the other. For some time the University professors continued to deliver their lectures in the theatre attached to Surgeons' Hall, but in the time of the first Monro they removed from there. In 1788 the College of Surgeons feued a piece of their ground adjoining their Hall to John Bell for the purpose of building thereon an anatomical school for himself, granting him permission to use their theatre until his own was built. John Bell was a pupil of the second Monro and was the first to start lecturing on anatomy as a rival to the recognised teacher of that subject. For years the building then erected continued to be a centre of anatomical teaching. The extra-mural teachers, as they are now frequently designated, include the names of John and Charles Bell, of Barclay, Gordon, Cullen, and Knox. It was in the rooms connected with, or gathered round, Surgeons' Hall that the extra-mural school which began with John Bell, and still continues to do so much for medical education in Edinburgh, at first found a home.

Before leaving those old times altogether it will interest some of the readers of this historical sketch to know the position which the surgeons took up in such an important national movement as the Protestant Reformation. An oath was required on entrance to the College binding them to "continue in the profession of Christ's blessed evangell as the same is publicly preached within this realm," and Dr. Gairdner thinks that "these words were clearly intended to exclude Roman Catholics." However that may be, the surgeons of Edinburgh signed the Covenant on August 25th, 1638, and "ordained their haill prenteisses and servands to subscryve the same als weill as themselfis, and that there sall be in no tyme cumming any freeman admittit, either chirurgeon or barbour, nor any buike prenteisses or servands, but sic as shall subscryve the Covenant." Needless to say, these tests have for long been things of the past.

Turning our attention now to more modern times, it is to be noted that the Royal Charter of 1851 not only finally freed the surgeons from their civic thraldom and gave to their corporation the name and title of "The Royal College of Surgeons of Edinburgh" but defined the mode both of admission to its Fellowship and of granting its Licence and gave disciplinary powers over both its Fellows and Licentiates. As a result of the Medical Act of 1858 the Royal College of Surgeons united with its sister college in Edinburgh to confer, after a united examination, a medical and surgical diploma which is still widely known as the Edinburgh double qualification. This conjoint examination was inaugurated at the Royal College of Surgeons in 1859 when the late Sir Douglas Maclagan occupied the presidential chair. In 1884 a further change in the same direction took place. This was the inclusion of the Faculty of Physicians and Surgeons of Glasgow in the foregoing arrangement and the institution of a common examination, the successful passing of which conferred upon the candidate the licences of the three corporations. This is known as the Scottish triple qualification.

After the passing of the Dentists Act of 1878 the College established a Dental Examining Board and a diploma in dental surgery conveying the designation of "Licentiate in Dental Surgery" (L.D.S.) to successful candidates. 11 years later, in 1889, the College, in conjunction with the Royal College of Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, instituted a qualification in public health making successful candidates "Diplomates in Public Health" (D.P.H.).

A few words regarding the Fellowship will complete the account of the College as a diploma-granting body. For many years the Fellowship of the College was conferred only on prominent licentiates, or on men who had attained local success or some degree of distinction in the practice of medicine or surgery. It was conferred by the vote of the Fellows. There was no intermediate stage between the Licence and the Fellowship. After discussion, spread over a number of years, the College determined in 1883 to open its Fellowship to examination and this was first acted upon in the following year. The College reserved, however, the power to dispense with the examination in notable and exceptional cases.

The list of distinguished men who have lectured at Surgeons' Hall is a long one and includes the name of Lister. The professoriate of the medical school in the University has been largely supplied by men who have lectured in the extra-mural school of which, as has been said, Surgeons' Hall was the centre. The freedom granted by the University to its students to attend a proportion of their classes under extra-mural lecturers has acted as a great stimulus to teaching in that school, which has reacted beneficially upon the University. The long list of "Deacons" and Presidents contains many names still held in reverence by Edinburgh men and not a few names of men who have left their impress deeply in the annals of progressive medicine.

Such is briefly the history of the College which has this week been celebrating its fourth centenary under the presidency of Sir Patrick Heron Watson, one of the most courtly men in the profession in Scotland and one of the last of the leading surgeons of the Edinburgh School who have practised both as surgeons and as physicians.

In the preparation of this sketch we desire to acknowledge our obligations to the historical researches of Dr. Gairdner, who was President of the College when its present Hall was opened; to Sir John Struthers's account of the Anatomical School of Edinburgh; and, lastly, to the interesting memento of the fourth centenary of the College written by Dr. John Smith, one of the past presidents of the College, and just published. Dr. Smith placed other literary material at our disposal and kindly granted permission to reproduce the view of Surgeons' Hall as it at present appears, which is from his facile pen.

Much might be written on the social qualities of successive generations of Fellows, of their song-writing and their song-singing, their wit and their humour, but those things are of local interest only, though by lightening the daily burden of professional life they have not been without influence on the progress of medical science in Edinburgh.

THE PREVENTION OF EPIDEMIC SMALL-POX.

A Conference on the Prevention of Epidemic Small-pox, which was attended by a great number of provincial mayors and representatives of municipal and rural authorities from all parts of the United Kingdom, was held at the Mansion House, London, on July 18th, the Lord Mayor being in the chair.

Mrs. Elizabeth Garrett Anderson, M.D., the honorary secretary of the Imperial Vaccination League, introduced the subject of the conference to those present in a few words. She stated in detail how extensively a memorial to the Government urgently pleading for obligatory revaccination had been signed by a great number of chief magistrates of towns in England, Scotland, and Ireland, and by chairmen of urban and district councils of places that had suffered from epidemic small-pox in the one and a half years ending July 1st, 1905.

Briefly stated, the reasons put forward in support of systematic revaccination at school age are that by the age of 12 years the protection against small-pox afforded by primary vaccination is in large measure worn out and children of that age when exposed to the contagion of small-pox are liable to take the disease, though for many years longer they would probably only have it lightly. The task of providing an adequate amount of glycerinised lymph would be much simplified by the demand for such lymph being nearly the same year by year. At present there is an enormous demand in epidemic years and a comparatively small demand at other times. Lymph is not prepared quickly or cheaply, and it does not keep for indefinite periods of time. If the Government knew approximately the number of tubes that would be wanted each year the problem of providing what is required would be much simpler than it is at present. Protection from small pox by systematic revaccination would be cheaper and very much more successful than by providing costly small-pox hospitals and attempting to deal with epidemic small-pox by the isolation of patients. There would not be any great practical difficulty in organising general revaccination. In the schools under the London County Council the number of children of the average age of 12·8 years forms 6·25 per cent. of the whole number of children in the schools. This percentage amounts to about 34,000 children who would have to be revaccinated in London each year in 521 separate schools. With whole-time officials the work could be done gradually and without any difficulty. Systematic revaccination has been the rule in Germany for many years, with the result that epidemic small pox is not known there. It has now been adopted also in France. No other means of prevention can be relied upon. The cost of providing isolation hospitals for small-pox patients is enormous and it tends always to increase, owing to the difficulty of getting sites and of working the hospitals at a considerable distance from all other houses. The great economic advantage of preventing the occurrence of epidemic small-pox by the general revaccination of children at school age was therefore urgently pressed upon the attention of the Government.

The conference emphatically endorsed the view expressed in the memorial that epidemic small-pox during the past 18 months had caused much suffering, destruction of property, increase of municipal expenditure, and interference with trade, and discussed from many points of view the great importance attached to the prevention of epidemic small-pox by the systematic revaccination at school age of all but the children relieved under the exemption clause and of those who for a time are excused on the ground of ill-health.

The Lord Mayor of York moved a proposition declaring that the continued recurrence of epidemic small-pox involved much needless suffering, waste of public money, and increase of municipal expenditure, and Sir William Broadbent, in seconding this, observed that if there were vaccination and revaccination as proposed small-pox would become unknown.

The Lord Provost of Glasgow gave statistical reasons in support of the proposition and Dr. J. G. Glover added to the information supplied to the conference by giving details concerning the outbreak of small-pox at Leicester.

After the proposition had been carried unanimously Sir William S. Church found no difficulty in showing that epidemic small-pox ought to be prevented in this country as it has been since 1875 in Germany by the systematic revaccination of children in their thirteenth year and his motion to that effect was seconded by Alderman J. Kilburn of Dewsbury and agreed to by the meeting unanimously.

The Duke of Northumberland, who was announced on the agenda paper as the proposer of a vote of thanks to the Lord Mayor for presiding at the meeting, was the next speaker, but instead of moving the vote of thanks he submitted the following motion which was carried unanimously:—

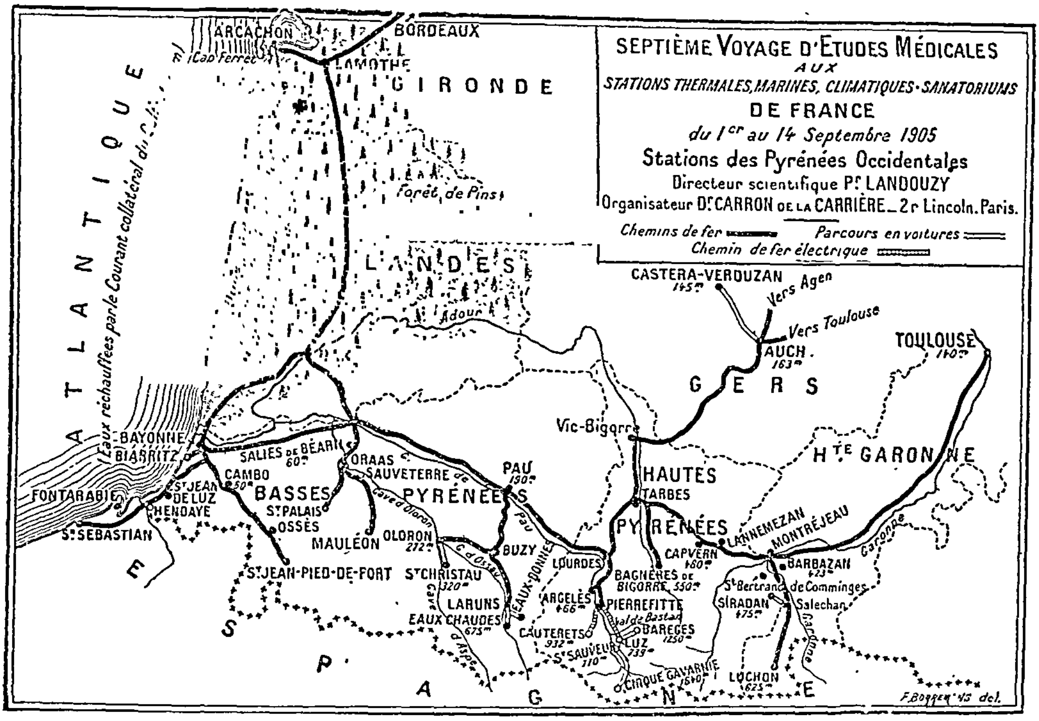
> That this meeting of Lord Mayors and Mayors, Lord Provosts and Provosts, and chairmen of the urban or rural district councils of such towns and localities in Great Britain and Ireland as have suffered collectively from upward of 480 separate epidemics of small-pox within the last 18 months, ventures to urge upon his Majesty's Government the great importance of preventing the recurrence of such epidemics by the systematic revaccination at school age of all but the children relieved under the exemption clause and of those who are for a time excused on the ground of ill-health.

This motion received hearty support from the Mayor of Preston and the Mayor of Birkenhead whose efforts were seconded by Mr R. Brudenell Carter who considered that the amount of security afforded by what were called sanitary precautions taken at Leicester was very inadequate for the requirements of the public. The motion was also supported by Dr. H. E. Armstrong of Newcastle-upon-Tyne.

This influential and important meeting terminated with a cordial vote of thanks to the Lord Mayor for presiding, which was proposed by Dr. E. J. Edwardes, seconded by Mrs. Garrett Anderson, and carried with acclamation.

VOYAGES D'ÉTUDES MÉDICALES.

THIS sketch map of the Western Pyrenees district illustrates the annual "voyage" arranged for Sept. 1st to 14th next and described in THE LANCET of June 24th, p. 1739. Anyone desiring full details of this journey should write to Dr. Leonard Williams, 8, York-street, Portman-square, London, W.



ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on July 13th, Mr. JOHN TWEEDY, the President, being in the chair.

The PRESIDENT reported that at a meeting of the Fellows held on July 6th Mr. Edmund Owen and Mr. R. J. Godlee were re-elected, and Mr. C. H. Golding-Bird and Mr. Harrison Cripps were elected members of the Council, as already reported in THE LANCET.

The PRESIDENT further stated that Mr. Cripps being fourth on the poll would become substitute member of Council for Sir Alfred Cooper.

Mr. Owen, Mr. Godlee, Mr. Golding Bird, and Mr. Cripps were introduced, made declarations in the terms of the oath prescribed by the Charter of 1800, and took their seats as members of the Council.

It was resolved that the museum should be closed during August and September to allow of the cleaning and re-painting of several of the rooms.

On the recommendation of the Library Committee it was resolved that £100 should be allowed for the repair of bindings of books in the library.

In accordance with the recommendations of the Committee of Management it was resolved that, subject to the condition that a visitor appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England should periodically inspect the examinations, candidates who have received the diploma in medicine and surgery of the Egyptian Government, after passing the required examinations and completing the curriculum of professional study at Cairo extending over four years, shall be admitted to the final examinations of the London Conjoint Board on the completion of one year of additional study at a recognised medical school and hospital in the United Kingdom, during which they shall complete the courses required by the regulations of the Conjoint Board.

The following professors and lecturers were appointed:—Hunterian professors (three lectures each): Mr. J. Warrington Haward, Mr. Arthur Henry Cheatle, Mr. Herbert J. Paterson, and Mr. Charles Gabriel Seligmann. Arris and Gale lecturers: Mr. J. H. Watson (two lectures) and Dr. S. W. Curl (one lecture). Erasmus Wilson lecturer (three lectures): Mr. James Sherren.

It was resolved to direct the removal from the roll of a Member who had previously been removed from the Medical Register.

The PRESIDENT reported the holding of the Fellows' dinner on July 6th and stated that Mr. Thomas Bryant, on behalf of the surviving members of the permanent committee of the Fellows' dinner, formerly held outside the College premises, had presented a loving cup to the College, together with the minute book of the committee giving particulars of the dinners held between 1846 and 1897. A vote of thanks to the permanent committee for these gifts was carried.

The PRESIDENT reported that the College had purchased from Mrs. Trimmer a silver tankard and two goblets, formerly owned by Sir Erasmus Wilson and presented by his executors to the late Mr. Edward Trimmer.

The PRESIDENT reported that as the representative of the College on the court of the University of Sheffield he had attended the opening of the University by His Majesty the King on July 12th and that in his absence the members of the Atlantic Union and other guests of the College had been received by the Vice-Presidents on the occasion of their visit to the museum.

The SECRETARY suggested that the names of the following Fellows, about whom nothing had been known for many years and who were probably dead, should be omitted from future editions of the College Calendar: Theophilus Miller Gunn, Member 1842, Fellow 1858; William Major, Member 1833, Fellow 1853; Frederick John Robinson, Member 1842, Fellow 1859; Thomas Seagram, Member 1833, Fellow 1856; Joseph Webb, Member 1839, Fellow 1856; and Frederick Whitfield, Member 1825, Fellow 1859.

The PRESIDENT reported that questions had recently been raised as to the eligibility of a dental surgeon for call to the Bar but that in the case in question the dental surgeon, who was a Licentiate of the College, was duly called to the Bar on July 5th by the benchers of the Middle Temple.

The Council then proceeded to the election of officers for the ensuing year and (as announced in our columns last week) Mr. Tweedy was re-elected President and Mr. H. T. Butlin and Mr. Owen were elected Vice-Presidents.

A letter was read from Sir Henry G. Howse resigning his membership of the Committee of Management and Mr. Godlee was appointed in his stead.

A letter was read from Dr. S. H. Habershon stating that by the rules of the Convalescent Homes Association it was proposed that the President of the College should *ex officio* be a vice-president of the association and inquiring whether the College would assent to this proposal. It was resolved to approve of this.

It was resolved to send an address of congratulation to the Royal College of Surgeons of Edinburgh on the occasion of its fourth centenary celebration.

It was decided that the next meeting of the Council should be on July 27th.

THE ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS: ANNUAL DINNER.

THE annual dinner of this association took place at the Whitehall Rooms, Hôtel Métropole, London, on July 13th. Dr. J. Walton Browne, ex-President, in the unavoidable absence, through an accident, of the President, occupied the chair. After the toast of "The King" had been duly honoured that of "The Imperial Forces" was proposed by Mr. Joseph Walton, M.P., in a vigorous and, as it was afterwards alluded to by Mr. Wason, semi-political speech. Referring to the recent sad accidents to submarines, he thought that their use should be prohibited by international consent as barbarisms. The toast was replied to by Captain Hamilton, R.N., chief officer of the London Fire Brigade, who thought that so long as submarines were used England must have the very best, and by Surgeon-General A. H. Keogh, C.B., Director General of the Army Medical Department, who said, in view of a recent statement given in evidence by a highly competent medical witness that 40 per cent. of the Volunteers were unfit for war, it was necessary to ascertain undoubtedly whether that statement was true. For his own part he did not know but it would certainly be necessary to find out all the facts, for a war taking place in this country would be very different from those with which we had had hitherto to deal. The purpose of the Army Medical Service was to maintain the fighting efficiency of the army and an inefficient Medical Service meant disaster. Efficiency was the thing to be looked for and must be attained at any cost. He referred to the Commission appointed to inquire into and to report upon the care and treatment of the sick and wounded during the South African War and its recommendations and said that every one of those recommendations was being carried out. He gave high praise to the Treasury, remarking that the proposals had received from the Treasury every possible support. He was glad to think that the Army Medical Service was progressing satisfactorily but he would remind the country and he would remind the medical profession that in times of peace no interest was taken in the medical department and he trusted in future that that would be remedied. Colonel S. Raffles Thompson, late assistant secretary to the General Post Office, also replied and strongly supported Mr. Arnold-Forster's recently issued circular with regard to the Volunteers, remarking that it was simply common sense. "The Houses of Parliament" was proposed by Mr. Stanley Leathes, secretary of the Civil Service Commission, and replied to by Mr. J. Henniker-Heaton, M.P. The toast of "The Postmaster-General, the Secretary, and other Executive Officers of the Post Office" was proposed by Dr. R. Paramore and responded to by Mr. C. H. Bundy, assistant secretary to the Post Office, who remarked that in 1854 there were no postal medical officers whatever. In 1855 one was appointed. In 1859 the capitation system came into existence and medical officers were appointed in London. In 1870 this was extended to the provinces. Last year—viz., 1904—however, there were 1830 postal medical officers and 800 more were about to be added, probably in the course of the present year. "The Association of British Postal Medical Officers" was proposed by Mr. Eugene Wason, M.P., who referred to the medical officers as the Intelligence Department of the Post Office and rendered a high tribute to their work and value. The Chairman, in reply, paid a well-deserved compliment to Dr. R Ritchie Giddings, the honorary secretary, and alluded to the social advantages of the Association. "Our Guests" was proposed by Dr. E. L. Adeney and replied to by Sir Robert Hunter, solicitor to the Post Office. During the dinner a programme of music was performed by the Imperial Quintet and the intervals between the speeches were enlivened by songs by Miss Esther Franklin, Miss Clara Walker, and Mr. George Burdge.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances and Administration of the Urban District of Nantyglo and Blaina and on Prevalence of Infectious Disease in the District, by Dr. W. W. E. FLETCHER.[1]—This report relates to a Monmouthshire colliery district, with a population of about 13,500, in which a variety of difficulties appear to have arisen in connexion with sanitary administration. Notification of infectious diseases did not come into operation here until 1900. During the five years 1900-04 the notified cases of scarlet fever, diphtheria, and enteric fever have been exceptionally numerous—respectively 558, 1174, and 207. Dr. Fletcher gives the figures for notifications and deaths from each of these diseases during various periods in considerable detail and he has also classified them by age groups. These data show that the district must be included among those with a persistently high attack rate from enteric fever and corresponding mortality from this disease. They show also that the scarlet fever prevalence, though noteworthy in certain years, has not been excessive when the whole period is taken. But with regard to diphtheria the conclusions are much more doubtful. Dr. Fletcher raises the question whether this disease has not been notified in a somewhat loose manner by certain of the medical practitioners in the neighbourhood. Five out of 32 practitioners were responsible for the notification of 949 of the 1174 cases of diphtheria; one practitioner alone notified 429. Dr. Fletcher is of opinion that a strong probability that many of these were not diphtheria is afforded by the low case mortality. Antitoxin seems to have been employed freely but the Metropolitan Asylums Board, with all its resources, added to the use of antitoxin, has only succeeded in reducing the case mortality of the county of London to 10·8 per cent. in 1901 and 1902 and to 9·6 per cent. in 1903, whereas, on the notification figures, Nantyglo and Blaina during a period of four and three-quarter years showed a case mortality of only 4 per cent. It should be noticed also that swabbings from the throat were examined bacteriologically in only one instance. Dr. Fletcher is of opinion that although it may be proper to regard every case of throat illness during the prevalence of diphtheria as a potential source of diphtheria, capable of conveying infection, and consequently requiring isolation and careful watching, yet it would be difficult to justify the notification of every such case, and adds that he feels sure that local medical practitioners will agree on studying the facts set forth that diphtheria cannot have been as prevalent as the notifications suggest. Another difficulty in this district is occasioned by the large scale on which works of sewerage have to be undertaken. The district is now to be drained by the Western Valleys Sewerage Board and it is estimated that its share in the scheme of this board will entail a cost of about £45,000, a heavy burden to be placed on an assessable value of £41,000, even when spread over a long period of years.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on July 13th, Mr. JOHN TWEEDY, the President, being in the chair.

The PRESIDENT reported that at a meeting of the Fellows held on July 6th Mr. Edmund Owen and Mr. R. J. Godlee were re-elected, and Mr. C. H. Golding-Bird and Mr. Harrison Cripps were elected members of the Council, as already reported in THE LANCET.

The PRESIDENT further stated that Mr. Cripps being fourth on the poll would become substitute member of Council for Sir Alfred Cooper.

Mr. Owen, Mr. Godlee, Mr. Golding Bird, and Mr. Cripps were introduced, made declarations in the terms of the oath prescribed by the Charter of 1800, and took their seats as members of the Council.

It was resolved that the museum should be closed during August and September to allow of the cleaning and re-painting of several of the rooms.

On the recommendation of the Library Committee it was resolved that £100 should be allowed for the repair of bindings of books in the library.

In accordance with the recommendations of the Committee of Management it was resolved that, subject to the condition that a visitor appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England should periodically inspect the examinations, candidates who have received the diploma in medicine and surgery of the Egyptian Government, after passing the required examinations and completing the curriculum of professional study at Cairo extending over four years, shall be admitted to the final examinations of the London Conjoint Board on the completion of one year of additional study at a recognised medical school and hospital in the United Kingdom, during which they shall complete the courses required by the regulations of the Conjoint Board.

The following professors and lecturers were appointed:—Hunterian professors (three lectures each): Mr. J. Warrington Haward, Mr. Arthur Henry Cheatle, Mr. Herbert J. Paterson, and Mr. Charles Gabriel Seligmann. Arris and Gale lecturers: Mr. J. H. Watson (two lectures) and Dr. S. W. Curl (one lecture). Erasmus Wilson lecturer (three lectures): Mr. James Sherren.

It was resolved to direct the removal from the roll of a Member who had previously been removed from the Medical Register.

The PRESIDENT reported the holding of the Fellows' dinner on July 6th and stated that Mr. Thomas Bryant, on behalf of the surviving members of the permanent committee of the Fellows' dinner, formerly held outside the College premises, had presented a loving cup to the College, together with the minute book of the committee giving particulars of the dinners held between 1846 and 1897. A vote of thanks to the permanent committee for these gifts was carried.

The PRESIDENT reported that the College had purchased from Mrs. Trimmer a silver tankard and two goblets, formerly owned by Sir Erasmus Wilson and presented by his executors to the late Mr. Edward Trimmer.

The PRESIDENT reported that as the representative of the College on the court of the University of Sheffield he had attended the opening of the University by His Majesty the King on July 12th and that in his absence the members of the Atlantic Union and other guests of the College had been received by the Vice-Presidents on the occasion of their visit to the museum.

The SECRETARY suggested that the names of the following Fellows, about whom nothing had been known for many years and who were probably dead, should be omitted from future editions of the College Calendar: Theophilus Miller Gunn, Member 1842, Fellow 1858; William Major, Member 1833, Fellow 1853; Frederick John Robinson, Member 1842, Fellow 1859; Thomas Seagram, Member 1833, Fellow 1856; Joseph Webb, Member 1839, Fellow 1856; and Frederick Whitfield, Member 1825, Fellow 1859.

The PRESIDENT reported that questions had recently been "fever," and one to diphtheria, but not any to small-pox or scarlet fever. In all 55 deaths resulted from these principal infectious diseases last week, against 60, 65, and 57 in the three preceding weeks. These 55 deaths were equal to an annual rate of 1·6 per 1000, which was also the mean rate last week from the principal infectious diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 18, 31, and 26 in the three preceding weeks, declined again last week to 25, of which 15 occurred in Glasgow, four in Edinburgh, two in Dundee, and two in Aberdeen. The deaths from measles, which had been 13, 17, and 14 in the three preceding weeks, rose again to 19 last week, and included 11 in Glasgow, six in Edinburgh, and two in Perth. The fatal cases of diarrhœa, which had been 15, 14, and 13 in the three preceding weeks, further declined last week to seven, of which three were registered in Leith and two in Glasgow. The deaths from "fever," which had been three, two, and none in the three preceding weeks, rose again to three last week and all occurred in Greenock. The deaths referred to diseases of the respiratory system, which had been 74, 68, and 65 in the three preceding weeks, were again 65 last week, and were 16 above the number in the corresponding period of last year. The causes of 13, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17·9, 14·9, and 16·9 per 1000 in the three preceding weeks, rose again to 19·7 per 1000 during the week ending July 15th. During the past four weeks the death-rate has averaged 17·4 per 1000, the rates during the same period being 11·7 in London and 15·1 in Edinburgh. The 143 deaths of persons belonging to Dublin registered during the week under notice were 20 in excess of the number in the preceding week and included 17 which were referred to the principal infectious diseases, against six, seven, and eight in the three preceding weeks; of these, 14 resulted from diarrhœa, two from whooping-cough, and one from measles, but not any from small-pox, scarlet fever, diphtheria, or "fever." These 17 deaths were equal to an annual rate of 2·3 per 1000, the death-rates last week from the principal infectious diseases being 1·3 in London and 1·5 in Edinburgh. The fatal cases of diarrhœa, which had been two, two, and six in the three preceding weeks, increased last week to 17. The 143 deaths in Dublin last week included 45 of children under one year of age and 28 of persons aged 60 years and upwards; the deaths of infants were considerably in excess of the number in the preceding week, while those of elderly persons showed a slight decline. Four inquest cases and six deaths from violence were registered; and 61, or more than two-fifths, of the deaths occurred in public institutions. The causes of nine, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: E. B. Pickthorn to the *Iris*; G. H. Foott to the *Venerable* and C. G. Matthew to the *Resolution*, both on recommissioning: C. Strickland to the *Amphitrite*, on recommissioning; and J. W. O. Underhill to the *Hindustan*, on recommissioning. Staff Surgeons: A. Maclean, to the *Sappho*; B. F. Parish to the *Ariadne*, on recommissioning: and F. H. A. Clayton to the *Victory*, lent to the *Brilliant*. Surgeons: A. A. Chancellor to the *Venerable*, on recommissioning; J. W. Myles to the *Flora*, on completing; and W. G. Edwards and W. E. Ormsby to the *Victory*.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Arthur Stanley Nance has been placed on the retired list, at his own request (dated July 8th, 1905).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majors to be Lieutenant-Colonels (dated May 30th, 1905):—Brevet Lieutenant-Colonel Samuel Hickson, Henry J. Fletcher, Edward Davis, Simpson Powell, Frederick W. C. Jones, James Meek, Arthur E. Morris, Robert E. Molesworth, Charles L. Josling, William T. Swan, Robert L. R. Macleod, Gofton G. Adams, James M. F. Shine, William B. Day, Charles T. Blackwell, Nicholas C. Ferguson, C.M.G., Samuel R. Wills, Michael L. Hearn, Richard H. Hall, Richard G. Hanley, Gerald Cree, Samuel C. Philson, John M. Nicolls, Frederick W. H. D. Harris, and James H. Curtis. The undermentioned Lieutenants are confirmed in that rank:—Robert G. Anderson, Charles P. Thomson, Robert J. B. Buchanan, George B. F. Churchill, George S. Wallace, William S. Nealor, Richard G. Meredith, Frederick E. Roberts, Arthur A. McNeight, Thomas H. Gibbon, James E. Hoar, Ernest B. Booth, Wilfred Parsons, Cecil D. M. Holbrooke, Ernest G. R. Lithgow, Pierce Power, James S. Pascoe, Charles W. O'Brien, George G. Tabuteau, Richard E. Humfrey, and William G. Maydon. Lieutenant-Colonel Frederick W. H. D. Harris retires on retired pay (dated July 19th, 1905).

INDIAN MEDICAL SERVICE.

A Royal Warrant has been issued, dated June 28th, amending the rules for promotion and precedence in the Indian Medical Service. The Royal Warrant dated Nov. 28th, 1903, is to be amended thus:—

The following is to be added to Article 1: "The Director-General of Our Indian Medical Service shall hold the substantive rank of surgeon-general, but may rank as lieutenant-general when approved by Our Secretary of State for India in Council."

The following is to be substituted for Articles 3 and 4:—"3. Except as otherwise herein provided, a captain shall be promoted to the rank of major on completing 12 years' full pay service, but this period may be reduced by six months in the case of an officer who produces satisfactory evidence of progress in any branch of knowledge which is likely to increase his efficiency. 4. Except as otherwise herein provided, a major shall be promoted to the rank of lieutenant-colonel on completing eight years' full pay service in the rank of major."

The following is to be added to Article 10: "An officer below the rank of colonel, who may be appointed as Our honorary physician or surgeon after retirement from the Service, shall be granted the honorary rank of colonel."

The following is to be inserted in Article 12 at the head of the table of ages at which officers shall be placed on the retired list: "Director-General, 62."

ROYAL ARMY MEDICAL CORPS (MILITIA).

Supernumerary Lieutenant (Honorary Lieutenant in the Army) W. H. G. H. Best to be Captain and to remain seconded (dated April 30th, 1905); Supernumerary Lieutenant (Honorary Lieutenant in the Army) H. Fox to be Captain and to remain seconded (dated May 28th, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain J. T. K. Thomson, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated July 19th, 1905).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Ayrshire and Galloway: Surgeon-Lieutenant R. C. Robertson resigns his commission (dated July 15th, 1905). 2nd Lancashire: Surgeon-Captain H. R. Jones resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated July 15th, 1905).

Royal Engineers (Volunteers): 1st Middlesex: Surgeon-Lieutenant T. H. Chittenden to be Surgeon-Captain (dated June 26th, 1905).

Rifle: 2nd Volunteer Battalion the Loyal North Lancashire Regiment: Surgeon-Lieutenant H. J. Taylor to be Surgeon-Captain (dated July 15th, 1905).

DEATHS IN THE SERVICES.

The *Army List* for this month contains a notice of the death of an army medical officer who may be correctly termed a veteran of that department, Deputy Surgeon-General Andrew Semple, M.D., who died at Edinburgh on May 16th at the age of 76 years. This officer, who was a man of kindly disposition, had led since his retirement from the service a very quiet and unobtrusive life but, as will be noticed from the following record, he had seen a good deal of active service in his time. Deputy Surgeon-General A. Semple, Army Medical Department, joined the army in November, 1854, and retired in 1881. He served in the Crimean campaign, 1854–55, and was present at the siege and fall of Sebastopol and at the attacks on the Redan of June 7th and 18th (mentioned in despatches, medal with clasp). He also served in the

Practically all the old privies in the district have been replaced by water-closets but the district council has not insisted upon satisfactory closets being provided. Most of the latter are "hand flushed" and nearly all have been put in by unskilled workmen. The result has been the comparatively recent creation of a series of nuisances which in their degree are as objectionable as those which were caused by the privies. Dr. Fletcher points out the necessity of better administration in these and many other matters, such as housing, both for the general improvement in the sanitary state of the place and for diminution in the prevalence of enteric fever. The office of medical officer of health is miserably paid and Dr. Fletcher urges the advantages of a combination of districts in this part of Monmouthshire to secure the services of a health officer who is independent of private practice.

On an Outbreak of Enteric Fever at Denaby Main, in the Doncaster Rural District, by Dr. R. A. FARRAR.[2]—Denaby Main is a colliery settlement near Doncaster, occupied mainly by men employed at the Cadeby and Denaby Main Collieries. It consists of two portions, separated from each other by a wide open space—New Conisborough, with 936 houses and a population of 4830; and Denaby, with 698 houses and 3490 inhabitants. The houses are of good and comparatively modern construction; there is a constant and satisfactory public water-supply from deep wells at Cadeby Pit; an efficient system of sewers has been provided. In the autumn of 1904 enteric fever was prevalent in certain villages in the Doncaster rural district and attacked Denaby Main with considerable intensity. In New Conisborough 59 cases were notified between August 4th and Nov 6th—one other had been notified on July 16th. Of these 60 cases 43 were males and 17 were females; nine deaths occurred. In Denaby 25 cases occurred between August 16th and Oct. 7th. The interesting point of these outbreaks is their limited range. In New Conisborough nearly all the cases occurred in dwellings situated in two adjoining and parallel streets and in Denaby a similar limitation to a small portion of the settlement was noted. Dr. Farrar discusses the etiological questions involved in considerable detail. At first it appeared possible that the local water supply of the two streets affected in New Conisborough was at fault. These streets, or parts of them, receive their water from a branch main which, near its origin, was found to have been left exposed for several months before August, when a small portion of it was relaid and it was covered up. The result of Dr. Farrar's inquiries as to the opportunities of insuction of infectious matter into this branch main, in consequence of this interference or otherwise, was, however, negative. He was also able definitely to exclude milk as a source of infection. The probable origin of the New Conisborough outbreak, he concludes, was the presence in certain of the capacious privy middens of the affected streets of specifically infected matters derived from the earliest cases which occurred. There was evidence that flies were present in great abundance in the village during the autumn months and Dr. Farrar suggests that the effect of flies settling on these middens and afterwards carrying infection to articles of food may have been limited in its results to the houses near the middens in question. As he says, our knowledge of the range of flight of the house fly is very limited, but it is possible that when food is abundant this range is very short. Something of the kind has been shown to occur in the case of mosquitoes. Dr. Farrar finds that the second localised outbreak, in Denaby, would be explicable in a similar way. In the affected streets at Denaby the privy-midden nuisance was as great as in New Conisborough and the testimony of householders to the unusual prevalence of flies was still more emphatic.

Reports on the Sanitary Circumstances and Administration of Districts appointing more than one Medical Officer of Health.—It is the custom of certain rural district councils to divide the area under their control between two or more medical officers of health, usually paying small or nominal salaries in each case. The Local Government Board appears recently to have given special attention to the sanitary conditions and the administration of rural districts in which these arrangements are made and has lately issued reports on inquiries by Dr. L. W. Darra Mair in respect of the Wrexham district (No. 210), by Dr W. W. E. Fletcher for Halstead district (No. 211), and by Dr. R. A. Farrar for Durham district (No. 213). In each of these reports the system of multiple medical officers of health is considered to be unsatisfactory and recommendations are made either for the appointment of a single health officer, or preferably for combination of the rural district with its neighbours for the purpose of securing a medical officer of health who is not also in private practice and is able to give sufficient time to public health duties.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8196 births and 3860 deaths were registered during the week ending July 15th. The annual rate of mortality in these towns, which had been 12·9, 12·7, and 11·6 per 1000 in the three preceding weeks, rose again to 12·9 per 1000 last week. In London the death-rate was 11·7 per 1000, while it averaged 13·4 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·7 in Hornsey, 4·5 in Kings Norton, 5·0 in Burton-on-Trent, 7·2 in Walthamstow, 7·4 in Reading, 7·6 in Handsworth (Staffs.), 7·7 in Southampton, and 8·0 in Great Yarmouth; the highest rates were 18·2 in Barrow-in-Furness, 18·4 in Merthyr Tydfil, 18·5 in Salford, 18·6 in Stockport, 19·1 in Bootle, 20·5 in Burnley and in Sunderland, and 23·1 in West Bromwich. The 3860 deaths in these towns last week included 486 which were referred to the principal infectious diseases, against 348, 371, and 388 in the three preceding weeks; of these 486 deaths, 241 resulted from diarrhœa, 99 from measles, 70 from whooping-cough, 34 from scarlet fever, 26 from diphtheria, and 16 from "fever" (principally enteric), but not any from small-pox. In Brighton, Reading, Coventry, St. Helens, Cardiff, and in nine other smaller towns no death from any of the principal infectious diseases was registered; among the other towns they caused the highest death-rates in Wolverhampton, West Bromwich, Aston Manor, Stockport, Birkenhead, Bootle, Barrow-in-Furness, Middlesbrough, and Rhondda. The greatest proportional mortality from measles occurred in Bristol, West Bromwich, Barrow-in-Furness, and Sunderland; from scarlet fever in Devonport and in Blackburn; from diphtheria in Barrow-in-Furness; from whooping-cough in Hornsey, Walthamstow, Aston Manor, and West Hartlepool; from "fever" in Devonport; and from diarrhœa in Norwich, Aston Manor, Stockport, Birkenhead, Liverpool, Bootle, Middlesbrough, and Rhondda. No fatal case of small-pox was registered either in London or in any of the large provincial towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been six, four, and five at the end of the three preceding weeks, had declined again to four at the end of last week; two new cases were admitted during the week, against one, one, and two in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2520, against 2427, 2473, and 2499 at the end of the three preceding weeks; 356 new cases were admitted during the week, against 325, 334, and 354 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 144, 140, and 90 in the three preceding weeks, rose again last week to 104, but were 51 below the number in the corresponding period of last year. The causes of 50, or 1·3 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bradford, Leeds, Hull, Newcastle-on-Tyne, and in 47 other smaller towns; while the largest proportions of uncertified deaths were registered in Brighton, Norwich, Birmingham, Leicester, Liverpool, St. Helens, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 15·1, 16·5, and 14·7 per 1000 in the three preceding weeks, further fell to 14·3 per 1000 during the week ending July 15th, but was 1·4 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·2 in Leith and 11·5 in Aberdeen to 22·9 in Perth and 29·7 in Greenock. The 481 deaths in these towns included 25 which were referred to whooping-cough, 19 to measles, seven to diarrhœa, three to does, exist without any of these properties. That the particular gametoid tissue associated with cancer possesses them no one, we think, is likely to dispute. Thirdly, it is stated that "they particularise their meaning by drawing an analogy with what they have described in apospory where the new prothallus (reduced tissue) is said to eat its way backwards along the fern frond from which it has arisen." With regard to the first part of this statement the General Superintendent is obviously under some misconception. We have never made any original contributions to apospory in *this relation. The phenomenon* has been generally described by Professor Bower and others. It is well known to fern fanciers and Dr. E. F. Bashford is apparently not acquainted with the fact that prothallial tissue is sometimes formed without any reduction taking place. With regard to the latter part, we have pointed out that in different parts of certain tumours cells of somatic, heterotype, and homotype characters are markedly in evidence, which is something very different in form and in substance from the above assertion. Besides which, all these facts were subsequently confirmed by the observations published by the Superintendent of Research himself. Fourthly, it is stated that:—

---

[2] Ibid., No. 216, price 9d.

> An integral part of their explanation of cancer is based upon their view that the reproductive tissues proper arise merely by a transformation of somatic tissue. A similar change occurring at abnormal sites and times gives rise to the modified reproductive 'gametoid tissue, which is cancer.

To begin with, the discovery that reproductive tissue arises by a transformation of somatic cells is in no way due to us. In the young soma of various animals the reproductive tissue becomes differentiated from it at various periods. With regard to the latter part of the above statement, we never supposed, since it does not appear to be the case, that similar changes in abnormal sites necessarily give rise to cancer, for example, Bidder's organ in the male toad. It will thus have become obvious that instead of the epitome of the gametoid theory contained in the report under consideration presenting an accurate statement of our views, of the four principal statements into which it is divisible it may be said: The first is inaccurate. The second is inaccurate. The *third* and fourth are equally inaccurate and that together they constitute nothing more nor less than a complete misrepresentation of the position we have taken up.

These somewhat necessary corrections having been accomplished we would gladly have left the whole report for some more edifying occupation, but, as will be found in its concluding pages, the General Superintendent posts up a number of alleged characteristics which *he definitely states* collectively embody the fundamental characters of cancer and to which all hypotheses and theories whatsoever must necessarily conform. Without more than stopping to suggest the fact that where observations do not agree with the alleged characteristics of anything it is generally so much the worse for the alleged characteristics, we append these statements as they stand with the author's comments upon his own misrepresentation of our views on the right-hand side and lettered A to H for reference.

A.	Circumscribed nature of primary area or areas.	This was not clearly realised by the authors. The hypothesis implies a progressive transformation of somatic into modified reproductive tissue.
B.	Relative independence.	Tissue, with half the somatic number of chromosomes has this property in plants, and independence is postulated *for* the similar tissue alleged to constitute the essential part of malignant new growths.
C.	Power of continuous growth.	Postulated for the "gametoid tissue" of cancer.
D.	Infiltrative and destructive character.	The authors recognise an analogy for the infiltrative and destructive character of cancer in the similar behaviour of tissue with half the normal number of chromosomes in plants, and at the same time admit that the infiltrating margin of malignant new growths in man consists of cells with the normal number of chromosomes.
E.	Metastasis formation.	It is said to be due to the continuous introduction of cells which have undergone the change into "gametoid tissue."
F.	Age incidence.	This is not explained by the hypothesis.
G.	Single differentiation.	This has not been realised by the authors. The cells are stated to *assume the appearance of indifferent germ tissue.*
H.	Transmission with all its limitations.	Its limitations and nature are not taken into account. Actual contact. Continuous introduction of cells. Continuous application of suitable stimulus under very peculiar conditions.

(A) This was, and is, one of the characters of cancer with which we have been primarily concerned. After much consideration we are not clear what hypothesis is meant, but no suggestion of ours implies anything of this sort.

(B) Tissue with half the somatic number of chromosomes has sometimes, but not always, this property in plants. Reduced tissue is not regarded by us as constituting the essential part of malignant new growths.

(C) Power of continuous growth is not a peculiar property of cancer. Poplar and pear tree grafts exhibit it admirably. Consequently, in accordance with the dictates of prudence and discretion, no such postulate was made by us. In this connexion one may go further. The unlimited powers of growth, recognised by everyone in cancer, are paraded through the long length of the report as one of the chief attributes of the disease and the discernment of it as one of the chief results of the work in the laboratory of which Dr. Bashford is in charge. To us this so-called discovery seems nothing better than a needless recognition of what has been known to biologists for years.

(D) This paragraph might stand, but it would be better were the word "state" substituted for the word "admit."

(E) No statement that we have made involves "continuous introduction of cells."

(F) One was under the impression that the researches of Maupas, Hertwig, and others on the senility occurring under certain conditions in protozoon swarms brought this matter into conformity with the interpretation that we have put upon our observations.

(G) This matter was fully considered and whether as in some cases the cells do or do not assume the characters of young tissues is from our point of view of no importance.

(H) Its limitations are interesting in themselves, but in no way affect our position.

It might seem that since the epitome of the gametoid theory was previously shown to contain nothing but an inefficient travesty of the views it professes to portray comment upon the involved statements in the above table was unnecessary. A little consideration will, however, show that this is not the case. In the table hypotheses attributed to us are criticised in relation to a number of *formulæ*, some of which, like the continuous growth statement, have no significance and all of which are open to the most obvious objections. Consequently it is most necessary to make clear the manner in which assumptions that are not ours are made to appear as if governed by criteria we should instantly repudiate. In other words, the Superintendent criticises as ours statements we never made, and then tries them by tests which, had we made such statements, we should certainly not admit as having any value. Moreover, it appears that Dr. Bashford cannot have apprehended the logical termination of his own assertions. It should be pointed out that, provided his own observations upon the alleged fusion of the nuclei of cancer cells be valid, his acceptance of the gametoid theory is a logical necessity. Such fusions, preceded by the heterotype and homotype mitoses we originally observed, observations which he himself has subsequently figured and confirmed, are without meaning unless the original tissues in which reduction has occurred are assumed to have acquired the characters of reproductive elements, to be able to fertilise each other—that is, to have become gametoid in process.

Either Dr. Bashford and Dr. J. A. Murray are wrong in their observations upon nuclear fusion, or they have themselves produced the trump card in the gametoid theory they

Abyssinian campaign, 1867–68 (medal); and in the Zulu campaign, 1879, when he was present at the battle of Ulundi (mentioned in despatches, medal with clasp). Deputy Surgeon-General Semple was unmarried and, owing to his modest and retiring habits, was a man of far more learning and culture than might have been supposed by those who did not know him well.

THE QUEEN AND THE RED CROSS.

It having been recently decided, at the suggestion and under the auspices of their Majesties the King and Queen, that it was most desirable to form a new Red Cross Society, in view of coördinating all existing societies which are concerned with the succour of the sick and wounded in war, a council under the presidency of the Queen has been appointed for that purpose. On the occasion of the first meeting of this council at Buckingham Palace on July 17th, at which the Queen personally presided, Her Majesty made a very graceful speech setting forth the nature and the objects of the new scheme. The Queen appealed to all the women of the empire to assist in carrying it out on the ground of its being essentially a woman's mission and work and the only practical way in which they could lend aid and succour to the army and navy in time of war. The purpose of the new movement is to incorporate the Red Cross Society, established some 35 years ago, with the National Aid Society. There is no need at the present time to set forth the vast benefits which have accrued from such societies. Their aims naturally appeal to our instincts of humanity. But to get the best obtainable results from them it is essential that there should be careful preparation and organised unified effort beforehand. The council appointed by their Majesties, under the presidency of the Queen, has Lord Rothschild as chairman and Lord Knutsford, Lord Esher, Lord Cheylesmore, and Mr. A. K. Loyd, M.P., as vice-chairmen.

THE QUEEN'S VISIT TO THE ARMY HOSPITAL, MILLBANK.

The Queen paid a surprise visit to the military hospital at Millbank on the afternoon of July 18th. Her Majesty was accompanied by their Royal Highnesses the Princess Victoria, the Duchess of Sparta, and Princess Frederick Charles of Hesse. The Hon. Sidney Greville was in attendance.

MEDICAL HISTORY SHEETS IN USE IN THE ROYAL NAVY.

In view of the importance of the medical history sheet for the purpose of diagnosis and of deciding claims for pension or gratuity in the case of invaliding the Admiralty has approved of the following rules being observed for the better security of these documents: "1. The medical history sheet should always accompany the parchment certificate until the man has been discharged from the service, when the history sheet should be sent to the Medical Department of the Admiralty. If a history sheet is missing the fact is to be at once made known to the ship or depôt whence the history should have been received, which will be held responsible for its being replaced. 2. All ships, depôts, and hospitals not already having them will in due course be supplied with locked cupboards, with pigeon-holes alphabetically arranged, for the custody of the medical history sheets. 3. Medical history sheets are never to be allowed in the possession of any petty or non-commissioned officer, man, or boy. 4. At inspections the senior officer is to insert on the paper of inspection a note as to whether the rules respecting medical history sheets are properly observed."

THE WAR IN THE FAR EAST.

All that need be said regarding the news, which is mainly of a military and non-medical nature, from the theatre of war is that the island of Sakhalin is once more in Japanese hands, that General Linievitch's forces in Manchuria are stated to have been reinforced strongly, that Marshal Oyama's forces still remain relatively inactive, and that their Russian adversary is said to have relinquished the idea of making a big offensive movement in favour of one of a defensive character and has accordingly been concentrating his efforts in strengthening the works and position in this respect. It is feared that the railway from Harbin to Vladivostok will be cut within a short time by the Japanese. The heat is at present described as being great and the rainy season, so inimical to any active military operations, has set in. So far as we have any statements about the sanitary and health conditions of the enormous armies in the field the soldiers comprising General Linievitch's forces are said to have been suffering of late a good deal in health but the accounts are conflicting and untrustworthy. There would seem to be a widely prevalent and possibly growing feeling of disaffection and unrest in Russia and Russian Poland, and it is not to be wondered at that under existing conditions fears of coming famine and epidemic sickness have been expressed. Meanwhile arrangements are going on for the projected peace conference with varying statements from time to time, hopefully confident or otherwise, as to their progress.

Correspondence.

"Audi alteram partem."

SCIENTIFIC REPORT OF THE IMPERIAL CANCER RESEARCH FUND.

To the Editors of THE LANCET.

SIRS,—It is in no way our present purpose to comment upon the long statistical sections of the report recently issued by the executive committee of the Imperial Cancer Research Fund, for these, though of no special import in the present, will undoubtedly be useful at some future time. In the concluding paragraphs, on the other hand, we find what professes to be an epitome of the work of various authors, and here the matter is of a very different kind. The General Superintendent of Research produces a number of short statements which are intended to convey, for reference and for study, the conceptions of individual investigators, and these are prefaced by the following remarks:—"It will serve to delimit the directions in which the explanation of the growth of cancer must be sought if we review the various theories and hypotheses which still find currency as explanations of the nature and origin of cancer, and incidentally of its powers of growth." That such an undertaking is desirable no one is likely to dispute, but in order that it may have any value it is necessary that it should be not only an accessible, but also an accurate, statement of the works with which it deals. In view of the importance of the last condition it consequently appears necessary to draw the attention of your readers to the manner in which it is fulfilled in what professes to be a statement of the conceptions of Professor J. B. Farmer and ourselves regarding the "gametoid" nature of malignant growths. In thus limiting the discussion it is not in any way implied that we agree with the preceding matter of the report. We desire simply to draw attention to the character of a single section. After quoting a portion of a preliminary communication made in 1903 in the Proceedings of the Royal Society and without any reference to subsequent papers by ourselves, the General Superintendent proceeds as follows:—

> The views Prof. Farmer and his colleagues have elaborated amount to stating that malignant new growths arise by the transformation of the differentiated body tissues into reproductive tissue of modified character, which they specify by the term "gametoid," to distinguish it from the true gametogenic or reproductive tissue. They ascribe powers of proliferation, independence, and malignancy to this "gametoid tissue," whic [illegible] tissue, i.e., with half the somatic num [illegible] the surrounding tissues. [illegible] an analogy with what they [illegible] prothallus (reduced tissue) is said to eat its way backwards along the fern frond from which it h [illegible] detail in a malignant new growth three zo [illegible] to the spermatogonia, spermatocytes, and [illegible]

Firstly, then, and this is a very minor point, we are stated to ascribe the origin of malignant new growths to the transformation of differentiated body tissues into reproductive tissue of *modified* character. That is to say, we regard cancerous tissue as transformed reproductive tissue, for to be "modified" is to be altered or transformed. We may say that we never entertained any such idea. What we did say was that on the assumption of malignancy, tissues presented some of the characteristic features of reproductive cells—i.e., heterotypical and other mitoses with reduced numbers of chromosomes. In itself the use of the term gametoid implies that we regard these cells of malignant tissue as like, but not identical with, reproductive cells. Secondly, we are said to ascribe powers of proliferation, independency, and malignancy to gametoid tissue. We make no such general postulate. For anything that our observations indicate, gametoid tissue might, and possibly

THE USE OF PHENYLHYDRAZIN IN THE EXAMINATION OF URINE.

To the Editors of THE LANCET.

SIRS,—Dr. P. J. Cammidge in his recent paper[1] discourages the use of the water bath in using the phenylhydrazin test. This is an attitude not to be lightly assumed by one in the position occupied by Dr. Cammidge, for the water bath method has been so strongly insisted on by von Jaksch, Hirschl, and other authorities as a means of preventing the osazone compound of glycuronic acid from being precipitated in a crystalline form—a compound so likely to be mistaken for dextrosazone. According to Dr Cammidge this adventitious precipitation occurred in 4 per cent. of his cases when the water bath was used and only six times with the free flame. This experience is quite contrary to mine, for although I have not kept statistics on this point I find that I practically never meet with it since using the water bath, whereas when I used the free flame I used to meet with it occasionally. That the water bath method has advantages over the rapid method he admits when dealing with the microscopic examination of the crystals, for in referring to lactosazone he says: "In preparations made by the rapid method the individual crystals are not usually as distinct as those formed after prolonged heating in the water bath," and with regard to maltosazone he also says "preparations made by heating in the free flame are less characteristic." Both of these statements I can vouch for; indeed, the same is true of all the sugars. Surely the method whereby the best crystals are obtained is the one to adopt, for the identification of a sugar by means of the microscopic appearance of its osazone is practically relied on by clinicians. This, I need not add, does not apply to lævulosazone, for lævulose is the isomer of dextrose and their osazones are indistinguishable.

Dr. Cammidge also says that "in the water bath even an hour is not sufficient to obtain a satisfactory yield with maltose, lactose, and pentose, an hour and a half or two hours being required to demonstrate their presence satisfactorily, especially when the solution is weak." Here I quite disagree with him, for I find that half an hour in the water bath gives a good crop of crystals on cooling with aqueous solutions of these bodies of only 0·3 per cent. strength. Dr. Cammidge contradicts himself when dealing with the rate of osazone formation, for he says that "the osazones of maltose, lactose, and the pentoses only form after much more prolonged heating," whilst in the next sentence he says: "In my experience the rapid method of performing the phenylhydrazin test gives a reaction with all sugar." In dealing with the melting points Dr. Cammidge omits to give that of the glycuronic acid compound and the comparatively low melting point of 115° C. is one of its most distinctive features. I am, Sirs, yours faithfully,

L. C. S. BROUGHTON.

Langley Green, Birmingham, July 11th, 1905.

MOTOR SIGNALLING.

To the Editors of THE LANCET.

SIRS,—Will you give your valuable help towards getting an extended mode of signalling between drivers of motors and riders and drivers of horses? At present, in the day-time, there is only one signal—the uplifted hand. At night, the most important and dangerous time to the medical profession, there is none. When riding or driving a nervous horse in the day-time one does not want to bring every motor-car to a dead stop. It is often easier to drive such a horse past a slowly moving car than past one which is stationary and which has its engine going. I suppose the horse, like some sanitarians, thinks a moving smell less objectionable than a fixed one. In the day-time when meeting a driver I know I extend my arm at right angles to the trunk if I want him to slow down. At night the best way I have found for attracting a driver's notice is by covering the right lamp with the hand, using it like a "flash light" at sea. When meeting a motor in the dark this could be made to signify: right lamp covered once, go slow; twice, stop. In the case of a car coming up behind, the red light at the back could be used in the same way. It should now be made compulsory for all gig lamps to show a good red light behind. By a very simple method the driving lamp could be made to show any coloured light "fore and aft" and could be easily worked by the driver. There is no reason why good feeling should not exist between all users of the King's highway. Motors mean to stay, so we must make the best of them. If we can create a healthy public opinion the road hog (the present curse) will die of inanition.

I am, Sirs, yours faithfully,

Thrapston, July 17th, 1905. T. W. BUCKLEY, M.D. Durh.

THE PREVENTIVE TREATMENT OF CONSUMPTION IN AUSTRALIA.

To the Editors of THE LANCET.

SIRS,—I ask for a small part of your space to correct an error in the letter of "your own correspondent" in Australia published in THE LANCET of April 22nd. In a paragraph headed "Prevention and Treatment of Consumption" he writes, "Dr. Philip Sydney Jones recently gave an address ...... in which he advocated the isolation of every consumptive." I did not recommend so sweeping a measure as the isolation of *all* consumptives. What I did say was that the Government of the State should make provision for the isolation of advanced cases occurring among the poorer classes of the people and thus remove from our midst dangerous foci of infection. Your correspondent probably derived his information from one of our local newspapers which fell into the same error.

I am, Sirs, yours faithfully,

Sydney, May 30th, 1905. P. SYDNEY JONES, M.D. Lond.

FREEMAN *v.* APPERLY.

To the Editors of THE LANCET.

SIRS,—I am anxious through the medium of THE LANCET to thank most heartily those members of the London and Counties Medical Protection Society who have so kindly contributed to the fund raised to help me with the very heavy expenses entailed by the recent action for damages brought against me in the Gloucester county court. Though not a member of the above society until after the operation which resulted in this action I received most valuable help from its officers, both in advice and in the matter of witnesses, and now the society, though not liable in any way, has raised a fund among its members as a help towards my expenses. I do not wish what I intend as a letter of simple but warmest thanks to the generous members and officers of the society who have done so much to help me should resolve itself into a eulogy of the society itself, but I feel that it is only right that I should publicly acknowledge the kindness and generosity of its committee and officers, especially mentioning the names of Mr. A. G. R. Foulerton and Mr. C. W. Glassington, who have given so much time and have taken so much trouble on my behalf.

I am, Sirs, yours faithfully,

Mandeville-place, W., July 12th, 1905. E. APPERLY.

THE INFLUENCE OF FRUIT ON THE PRECIPITATION OF THE URIC ACID OF THE URINE.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will do me the favour of allowing me to state in your next issue that, through an oversight on my part, the word *is* appears instead of *may be* in the passage "the quantity thrown down *is* independent of this" (page 142) in my article with this title. I am, Sirs, yours faithfully,

Oxford, July 17th, 1905. WILLIAM J. SMITH JEROME.

MOUNT VERNON SANATORIUM AT NORTHWOOD.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 8th you say with reference to the report of Dr. A. W. J. MacFadden, medical officer of health of Edmonton, that "it seems almost a pity that some of the beds at the Mount Vernon Sanatorium at Northwood cannot be utilised by the sanitary authorities in Middlesex." As there it is, it does seem a great pity for some reasons that the whole of the Northwood institution is not set apart for are attempting to repudiate. In these circumstances it is not without a sensation of amusement that we offer them our opinion upon this matter, since it may deliver them from the horns of a dilemma between which they are at present absolutely pent up. We have never encountered anything in the least suggesting the fusions they have described and the figures and preparations of this process they have hitherto exhibited would convince no one who, having dealt with similar cytological matters, is familiar with the immense difficulty of observation and the abundant sources of misconception that are involved. On the other hand, the extraordinary behaviour of certain leucocytes in the earliest examples of malignant growths appears to supply this missing term in the gametoid theory. They are, however, wholly dissimilar in nature and position to the processes referred to above.

---

[1] THE LANCET, July 1st, 1905, p. 14.

Here, again, we would gladly have broken off and left others to form their own opinion of the final passages of this singular report, but since in these general biology is involved it seems necessary to lodge some protest against statements the true perspective of which may not be apparent to those who have assailed the cancer problem from its medical approach. It is here, moreover, that a curious unintelligibility often characteristic of the verbiage of the report breaks into full bloom. For example, on page 95 we read :—

Circumscribed nature of primary areas or area.	Proved to be an adequate explanation, by the reproduction of all the characters of sporadic growths by transplanted tumours.

On the left we have a statement posted as embodying an attribute of cancer. In the comment on the right this attribute is said to be an explanation of itself. One has encountered the apostle of the obvious but without exaggeration the present statement is equivalent to saying :—

Copper kettles have the characters of kettles made of copper.	Proved to be an adequate explanation by the production of copper kettles out of copper.

Again, on the same page—

Power of continuous growth.	Experimental propagation is a manifestation of this power of the parenchyma. Its unlimited, nature has been revealed by propagation, and indicates that an explanation of the amount of growth which suffices to kill the individual primarily affected, may be inadequate to explain the power of cell division which resides in malignant tissue as such.

We freely admit our limitations and state frankly that much study has failed to enable us to make out any kind of meaning in what is written in the right-hand column. One can only protest again that continuous growth is *not* a special character of cancer cells.

Again, on the same page :—

Infiltrative and destructive character.	Shown to be separable from mere growth of which it is probably a consequence.

To most people the assertion that thing B is a consequence of thing A implies that they are bound together, while mere growth, as in the case of a fibroma, does not of itself endow cells with the properties of infiltration and destructiveness.

It would be quite unnecessary, and certainly tedious, to go further, and there remains only the necessity to draw attention to one final passage of the report in which the author says :—

> The fresh light thus thrown on all the features of cancer has enabled us to prove what has long been surmised. The attributes of cancer are the mere consequences of its growth, which is its only constant property.

There is a triumphant and prophetic ring about the former of these statements, yet we have looked in vain through the pages of the report for the promised light. All that one finds is, "The attributes of cancer are the mere consequences of its growth"! We readily credit Dr. Bashford with the possibility that this sentence as it stands does not express his actual meaning. If it does we can only remark that it appears to be a wholly erroneous assertion. Surely the reducing divisions, the existence of "Plimmer's bodies" corresponding to the archoplasmic vesicles of sperm cells, and so on, are all attributes of cancer, but in what possible way can these be regarded as "mere consequences of its growth"? The statement is unintelligible.

In conclusion, let us, however, say that we regret, as much as any of your readers can do, the necessity for these criticisms, and that though sorely tempted we have endeavoured to keep what has been said within the limits of propriety. Some explanation is, however unavoidable. The reports of the Imperial Cancer Research Fund are widely read and nothing sticks like the mud of misconception when it is allowed to creep unchallenged into the publications of what ought to be an authoritative source.

We are, Sirs, yours faithfully,
J. E. S. MOORE,
Director of the Cancer Research, University of Liverpool.
C. E. WALKER.
July 10th, 1905.

THE PRINCIPLES OF HEREDITY.

To the Editors of THE LANCET.

SIRS,—In his recent Romanes lecture, entitled "Nature and Man," Professor Ray Lankester (page 28 and note 7) points out that in extra-human nature disease is a minor phenomenon; that individuals alone survive who can tolerate disease without injury, thus establishing immune races; that diseases are unknown as constant and normal phenomena except in man and domesticated races; that when diseases do become prevalent in nature they have been introduced by man or his domesticated herds. Thus the trypanosome lives in the blood of wild game and rats without producing mischief: the hosts are tolerant of the parasite. It is only when domesticated races are introduced, say into Africa, that disease becomes mischievous, so much so as in some regions to exterminate the big game. The disease does not establish itself as a scourge against which the diseased organism incessantly contends. It either obliterates its victims or settles with it into relations of reciprocal toleration.

In dealing with malaria Mr. D. M. Eder[1] says that it was formerly prevalent in England and that it is not now so presumably because, if Dr. Archdall Reid's reasoning be correct, the food-supply of the parasite has been exhausted and thus all Englishmen should be immune. That they are not immune is proved by Englishmen still suffering from malaria in our colonies. Without questioning what extent of England formerly suffered from malaria, nor whether the banishment of the disease is due to drainage, one is led to question whether Mr. Eder has really tried to understand the subject. Dr. Reid has pointed out that there are two diseases (tuberculosis and leprosy) immunity against which is inborn. For the other zymotics evolution has proceeded along lines of "an inborn capacity of acquiring capabilities for making resistance." This does not imply that those who are capable of acquiring immunity are insusceptible to infection. What it does imply is that those who have this power, other things being equal, are more likely to survive and continue the race. Nay, more, Dr. Reid has explicitly stated that though immunity against malaria may be acquired it is swiftly lapsed and thus re-infection is perhaps the normal condition. That immunity is not a question of food-supply is proven by microbes flourishing in the serum withdrawn from the body of an immune animal. As presumably each individual in West Africa suffers from malaria Mr. Eder's argument as to the food-supply breaks down. Again, surely Mr. Eder forgets or ignores the law enunciated by Dr. Reid that sexual reproduction is for the production of regression and if this is so how can a race become so immune that any disease by which it was formerly afflicted dies out?

Mr. Eder, in support of his contention that the Spaniards of unmixed descent are heavy drinkers—that is, drink for the mental effect—quotes the British Vice-Consul as saying "that intemperance is general among the working classes" of Oruro, Bolivia.[2] Yes, but Mr. Eder forgot to quote the preceding sentence that "the *half-breed* is the labourer of the country." With regard to the Jews Mr. Eder's experience seems to be unique. It is certainly the opposite of my own many years ago in Old Ford, and it is the opposite of those who practise largely in the Jewish district in Liverpool. If Mr. Eder has met so many Jewish alcoholics surely others must have met them also. Against a mass of evidence that can be adduced we have Mr. Eder's assertion. Which are we to believe?—I am, Sirs, yours faithfully,

C. R. NIVEN.
Liverpool, July 9th, 1905.

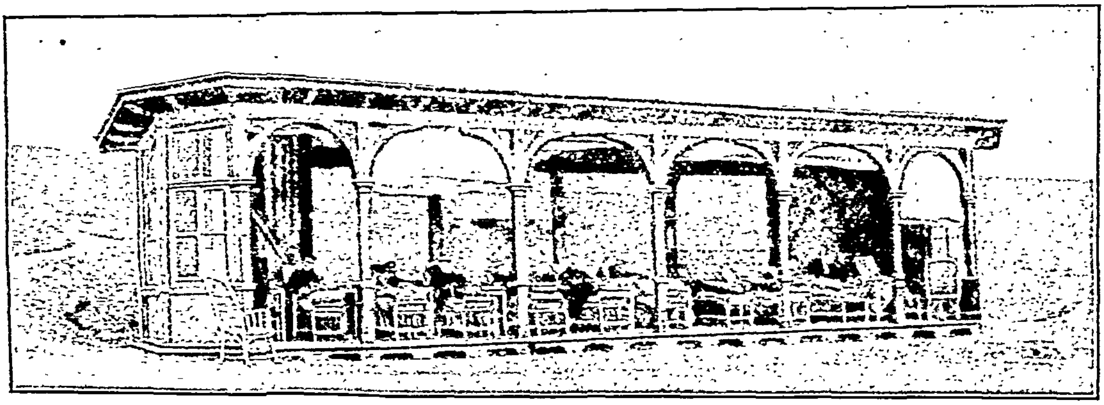
[2] THE LANCET, June

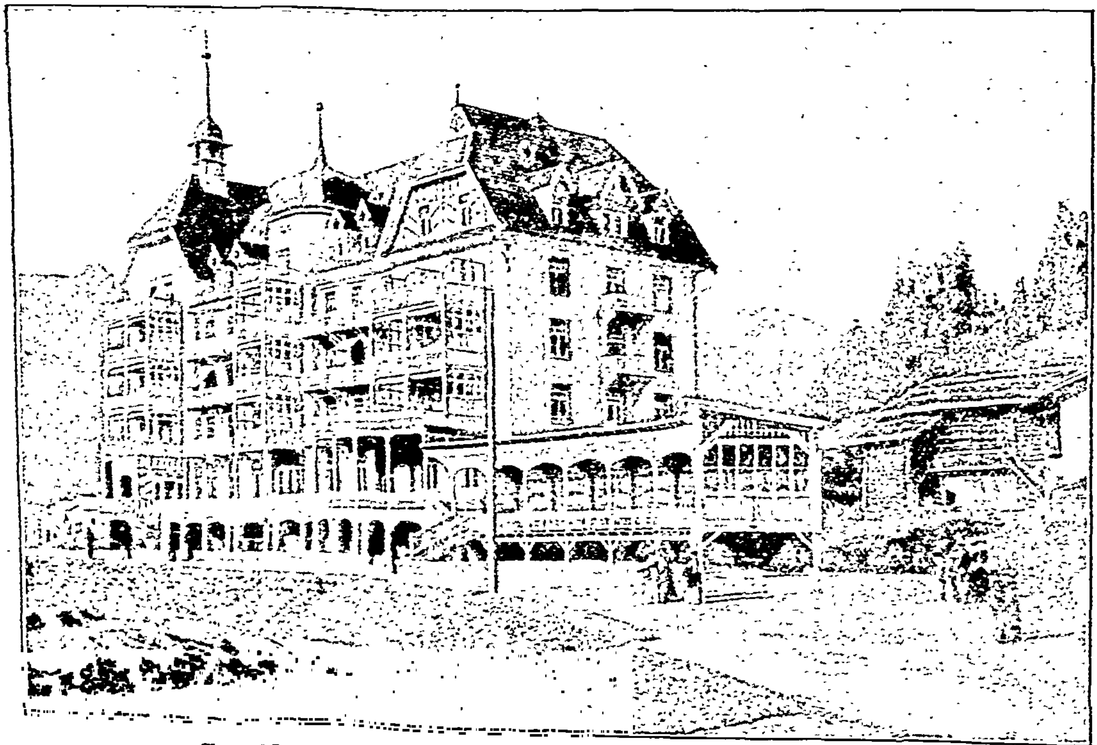
be opened or shut according to the direction of the wind. Thus while the amount of exposure to wind can be modified and the scorching rays of sunshine checked by canvas blinds, still the open air is enjoyed by the patients as they lie on good horsehair mattresses spread over their couches. Altogether in this sanatorium there is room for 90 couches in the open air and above them there is an electric light and by their side an electric bell. The estate on which the sanatorium stands consists of some 28 acres d there paths are carefully measured and have a fall rying from 4 to 10 per cent. Every 300 feet there are mbered benches for rest and the exercise prescribed can ns be measured out very accurately. The patient is told e number of the bench to which he must walk. On turning from this exercise he enters the cloak room where e hangs his overcoat or wraps in a partition made of well-led, pine-wood. Here the clothes of the different patients are kept apart; there is no contact. Under the clothes in the partition there is a zinc tray for damp boots or goloshes. The floors of the sanatorium are covered with linoleum resting on felt which deadens the sound. The walls are enamelled and only wet or moist dusting is allowed. The principle is that of the exaggerated washing of occupied rooms and of immediate disinfection when the patient leaves. What, however, impressed me most favourably was the kitchen. It may be said that as much—indeed, more—care has been bestowed on the kitchen than on the drawing room. In any case it is on the same floor, is quite as lofty, has, if anything, more windows, and is certainly quite as clean and bright in appearance. Two sides are all window, there is a window in the third wall, while the fourth wall separates the kitchen from the dining room.

FIG. 1.



Dr. Turban's Sanatorium at Davos-Platz: a shelter placed some distance in front of the main building.

FIG. 2.



Clavadel Sanatorium, Davos-Platz, showing broad balconies for the treatment of patients.

One and a half miles to the south of Davos-Platz, where the valley of the Sertig meets the Davos valley and at an altithe county in which it is situated. Middlesex could support it if it were placed under the management of its supporters but such control is a *sine quâ non*, as without it the support could not be obtained, nor if the money were available could the desired end be carried out. The worst of it is that Northwood is not an "open-air" sanatorium properly so-called; it is far too sumptuous to be suitable for working-class patients and it must be far more expensive to carry on than a more suitable building.

I am, Sirs, yours faithfully,
GERARD CLARK,
Honorary Secretary, Middlesex Open-air Sanatorium.
Ealing, W., July 12th, 1905.

PREGNANCY LATE IN LIFE.

To the Editors of THE LANCET.

SIRS,—Your article last week has suggested this communication, bearing mainly on the legal side of this matter.

Contrary to many foreign codes the common law of England allows no presumption that a woman (be she a spinster, a wife, or a widow) has passed an age when she can procreate and bear children. To the physiologist this is a matter of fact, dependent in most cases upon the menstrual climacteric, a phenomenon which is never "judicially noted as the invariable course of nature." For the purposes of forensic construction a woman, like a man, must be treated as capable of procreating children all her life, for the courts boast in this matter that they will never deprive a single living person of a possible interest or benefit. Lord Coke in 1624 stated a case relative to certain dowers which accrued if issue was born "albeit the wife be 100 years old ...... or the husband at his death was but four or seven years old, so as she had no possibility to have issue by him; yet seeing the law saith, that if the wife be above the age of nine years at the death of her husband she shall be endowed, and that women in ancient times have had children at that age whereunto no woman doth now attain, the law cannot judge that impossible which by nature was possible. And in my time a woman above threescore years old hath had a child—*ideo non definitur in jure.*" Lord Coke would have us refer apparently to Genesis xviii. 11, and I. Timothy v. 9. In legal practice the question arises to-day in several classes of cases. It may be requested that money shall be paid out of court to those contingently entitled to it in the event of a certain woman not having children, she being well past the alleged age of child-bearing; as a matter of practical convenience the court has gradually recognised the high degree of improbability of issue and early last century, in the case of a woman aged 69 years, a trust fund was disbursed, "the parties entering into sufficient security by recognisances." Gradually the age limit has been reduced until it is now about 54 years and lately security has been dispensed with. The plea, however, is never allowed to infringe the inviolable "rule against perpetuities." A similar question arose in the old ecclesiastical courts where a husband pleaded sterility in his newly married but aged wife; he was not allowed a decree of nullity of marriage, as it was affirmed that he had presumably taken her *tanquam soror*. Actuaries meet the problem in insurances against child-birth and policies taken out by women under 50 years of age. Cases of pseudocyesis are pertinent, as with Joanna Southcote in 1814, who was 64 years old when she claimed to be supernaturally pregnant. Disputes as to legitimacy and supposititious children occasionally occur in connexion with women past mid-age. To the medical mind it appears *primâ facie* that a medical certificate could, as a rule, summarily settle the facts. But the legal mind considers the admission of such a practice as well indecent as capable of too wide extension. In 1787 Lord Kenyon, then Master of the Rolls, when asked to declare that a septuagenarian couple were past the age for procreation, declared: "If this can be done in one case it may in another, and it is a very dangerous experiment, and introductive of the greatest inconvenience to give a latitude to such sort of conjecture." He was evidently suggesting that should medical evidence be admissible the principle could be applied to much younger women, sterilised perhaps by surgical means, and *pro tanto* to men. In matters marital the law will not often inquire beyond *habilitas ad matrimonium*, the practical test of which is mutual ability to consummate marriage.

I am, Sirs, yours faithfully,
LEGALIS.
July 18th, 1905.

DAVOS-PLATZ.

PRIVATE SANATORIUMS; PUBLIC AND POPULAR SANATORIUMS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

II.[1]

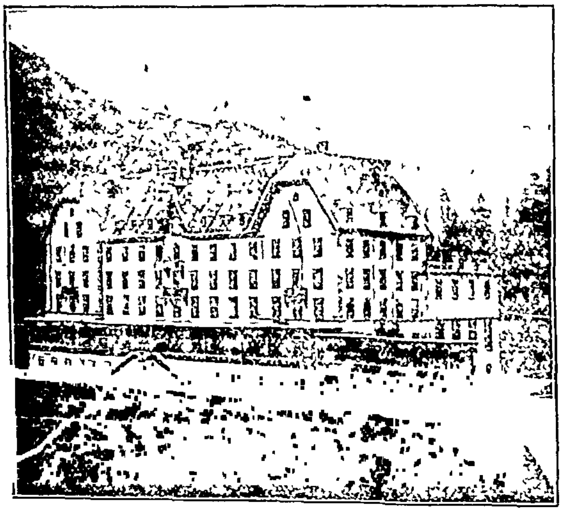
IN dealing with the sanatoriums at Davos it is not my purpose to criticise at any length those numerous and luxurious establishments which cater for paying patients. Doubtless they are open to not a few abuses but in any case if, in the desire not to displease good customers, patients are allowed more freedom than is good for their health, the law, as already described, takes care that they shall not injure or imperil others than themselves. There is at Davos-Platz and Davos-Dorf a great variety of hotels and sanatoriums. There are, as already mentioned, hotels for the exclusive use of healthy travellers and tourists, and these may be distinguished by the fact that they have no verandahs or broad balconies for patients to lie out in the open air and sunshine. Indeed, what is called at Davos "the cure" seems to consist, in the main, of what on the Riviera is called "a sun bath." The principal difference is that in the former place there is generally an accompaniment of snow. As a consequence, the method of taking the "sun bath" differs. On the Riviera the patient simply strolls out, generally to the sea front, takes his seat on a bench, faces the south, and allows the hot rays of the sun to pour down upon him. At Davos there is a verandah or balcony which shelters him from the cold wind but is open in front to the rays and the heat of the sun. Therefore the sanatoriums have to be built facing the south. Then in the verandah there are deck chairs or couches. But the cold is so intense that ordinary rugs do not suffice and very generally a sort of fur bag is employed in which the patient places his legs. The lying out in the cold, freezing air, with the bright sunshine in mitigation, is the main feature of the cure. There are therefore hotels and boarding-houses which simply provide their lodgers with board, bedroom, and a balcony or verandah where the patients may lie down in the open as long as they like. Such places can hardly be called sanatoriums. A patient may do well there if he receives good advice and carries out the instructions but there is no discipline or surveillance. These are merely hotels which admit patients. Other establishments are genuine sanatoriums under the direction of a medical man who has a staff of medical men and trained nurses to assist him. In fact, they are hospitals, luxurious hospitals, with drawing room, billiard room, music room, and library, with everything that can help to render life pleasant, but where, nevertheless, a strict discipline is enforced and the patients are only allowed such pleasures and relaxation as will not interfere with their cure.

Of these, one of the largest and best known is Dr. Turban's Sanatorium. Here every minute of the day is provided for. When not taking his prescribed walk the patient must be lying down in one of the "cure galleries" or sitting out in the garden, or else he is partaking of one of the six meals served during the course of the day. Of these two are heavy meals and, contrary to the practice at Nordrach Colonie, no exercise is allowed immediately after the more substantial meals. The *régime* is one of moderate overfeeding. The galleries, or verandahs, where the patients lie and breathe the open air measure in all some 330 feet in length. In front there is a band stand, so that occasionally music is provided as a diversion. Some years ago the air in these "cure galleries" was examined and it was not found to be affected by the presence of the patients. The ideal gallery is that which is built away from the main building. (Fig. 1.) On the southern side there are blinds only; on the northern side there are wooden partitions or shutters that may be lowered or closed according to the weather or the condition of the patients. In one part of the shelter the back wall, so to speak, may be lowered altogether, so that the patient may be left with only the roof over his head and the dry wooden floor beneath his feet which is raised a little above the ground. The next patient may have the partition raised above his body but still open overhead and this opening may be more or less wide or closed altogether. At the two extremities there are glass windows which may found disobeying orders in this or other respects run the risk of being expelled from the sanatorium and a threat to this effect generally suffices to secure the necessary obedience and discipline. They would not easily find elsewhere equally beautiful and healthy surroundings, medical care, and generous diet. They have two breakfasts—coffee, milk, bread, jam, and butter at 7.30 A.M.; and more bread, butter, cheese, and milk, alone or with a little coffee, at 10.30 A.M. Then there is dinner at 1 P.M., which consists of soup, meat, potatoes, and green vegetables, followed by stewed fruits and a special cake or pudding on Sundays. At 4 P.M. there are afternoon coffee, milk, and, on this occasion only, dry bread. At 7 P.M. they have supper consisting of soup and hot meat. The object is to make the patients eat a great deal.

---

[1] No. I. was published in THE LANCET of July 8th, 1905, p. 113.

FIG. 4.



The Basle Popular Sanatorium at Davos Platz.

As far as possible only patients in the early stage of disease are taken in, nevertheless some are sent who have already reached an advanced stage but who are without fever. The sanatorium has been open both summer and winter for eight years and excepting during the first few months has always been quite full. The strongest patients are given douches in the morning in a well-fitted bathing room, and at fixed hours, especially before meals, they are made to lie in the shelters and breathe quietly the pure air. Those who have no throat trouble may lie out of doors until 10 P.M. Indoors they sleep with their windows open and it is only when the weather is intensely cold that the lower part of the window is closed. Some of the bedrooms contain four patients but a separate room is given to natives of Basle for whom a payment of 4*s.* per day is made. For others the payment is 5*s.* 7*d.* All the walls are oil-painted and can be washed easily, though they are not enamelled. There is no difference in the food whatever payment may be made for the patients, the only difference being in the bedroom accommodation. In the dining room there are three rows of tables and the paying patients sit at the middle table. The medical and the managing staff and chaplain all take their meals with the patients and are content with the same food. There are always two—sometimes three—resident physicians. The kitchen has windows on both sides. The ceiling seemed rather low but the kitchen is above ground and large with plenty of room and air. The dining room also has windows on both sides so that a through draught can be easily established. There are several sitting rooms and a reading room. The partition can be removed in one case so that two rooms can be thrown into one, thus giving space enough for a prayer meeting or a concert or other entertainment. Outside there are a tennis ground, a shooting range, places for various games, and a carpenter's shop for those who wish to divert themselves by a little handicraft work.

FIG. 5

The Basle Popular Sanatorium at Davos Platz, showing surrounding scenery.

There now comes the great question of cost. It has been calculated that in 1902 and 1903 the average consumption of meat per day per head was 364 and 362 grammes respectively; bread, 224 and 221 grammes; butter, 28 and 26 grammes; cheese, 36 and 40 grammes; milk, 1·8 and 1·8 litre; and egg, 0·5 and 0·4. Thus, with the exception of milk and cheese there was a slight reduction in the amount consumed in 1903 as compared with 1902. The milk costs 2*d.* per litre and some 68,000 litres are consumed in the course of the year. The food actually eaten is supposed to cost on an average 1*s.* 8¾*d.* per day, but the general working expenses are put down at 3*s.* 0½*d.* per day per head. Though here and there a patient may pay 4*s.* a day most of the institutions that send patients to this sanatorium can only pay less than 3*s.* a day. 2*s.* a day is more like the usual figure, so that there is a constant deficit. The deficit would be still greater if an adequate sum was paid for interest and a sinking fund in regard to the capital expenditure. Consequently, frequent appeals have to be made for donations and charitable contributions. In 1903, 99 male and 102 female patients resided in the sanatorium. The proportion of deaths was equal to 0·9 per cent. and of those who derived no benefit 7·3 per cent. Of the 91·7 per cent. of those who were benefited 66·6 per cent. experienced what is described as the full economical effect of the cure. This means that they were able to return to their usual work. Others, to the extent of 20·2 per cent., were able to work but in a much less satisfactory manner, while 12·3 per cent. were not able to work at all.

It is satisfactory to know that an attempt is now being made on behalf of the English-speaking people to imitate the example given by the Germans, Dutch, and Swiss. A site has been purchased on which will be built what has already been denominated the Queen Alexandra Sanatorium. The cost of the land was £2918 and at the commencement of this year £7882 had been collected. It will be necessary to obtain more donations before a suitable structure can be erected; however, this will doubtless be accomplished in time and the British sanatorium will be able to profit by the experience already acquired in the immediate neighbourhood. Nor should there be any delay in the accomplishment of so useful and humane a work.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Royal Visit to Manchester and Salford.

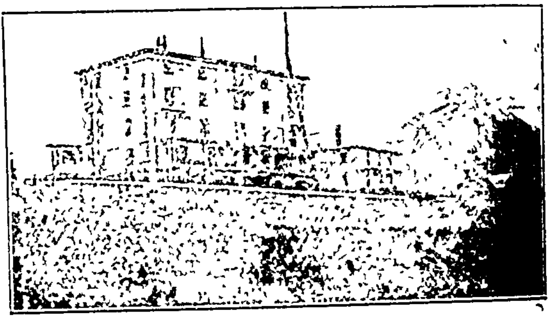
AFTER a most successful visit to Sheffield the King and Queen honoured Manchester and Salford with their presence on July 13th, where the whole population had for some time been full of eager and loyal expectation. London, tude of 5530 feet above the sea, is the ideally situated sanatorium of Clavadel. (Fig. 2.) The beauty of the surrounding scenery, the climatic advantages, the innumerable walks in the pine and larch forests, and the shelter which the mountains give are all topographical advantages that can only be found in these favoured Alpine valleys. At this spot the native population consists of five persons, aged from 70 to 91 and whose aggregate age is 407 years. This seems to speak well for the climate. The question, however, was to see what could be imitated elsewhere and especially in popular sanatoriums. First, I would say that here, as at Dr. Turban's Sanatorium, I was delighted with the kitchen which was above ground, lofty, and bathed with light. Here the cutlery was pointed out to me as of special make. The arrangement for the handles is such that repeated exposure to jets of steam under pressure will not make them fall to pieces. Thus the knives, the spoons, and the forks are not only washed but disinfected. The same naturally may be said of the plates and the cups. Excepting the hall and the dining room, where there is an oak parquet, the floors are made with a coating of cement, some felt, and then linoleum with three inches of excess in size so as to turn up on nearing the walls and thus to round off the angles. The walls and the ceilings are varnished and painted so as to be washable and the wood of the furniture is painted with white enamel. But here there is an important omission. Underneath and inside the chairs, tables, or drawers in the dark, shaded, and unseen places, where particles of dust are more likely to be dangerous, there is no enamel paint but the bare porous wood. It is difficult to make an ordinary upholsterer understand that from the health point of view it is precisely what cannot be seen that is the most important. The rooms are without hangings or carpets and that is a very good thing. Then the windows are large and lofty and can be opened at the top when the patient cannot endure the throwing open of the entire window.

The rooms looking in a southerly direction have balconies but some of them have balconies of exceptional size. Indeed, they constitute a sort of supplementary room which may be considered as being partially out of doors. But excepting at the top floor, where there can be no balcony overhead, these very broad balconies throw their shade on the window of the floor below and, to a large extent, prevent the rays of the sun entering the room beneath. (Fig. 2.) It is true that at Clavadel these very broad balconies are only attached to large corner rooms which have two windows but elsewhere this is not always the case. It is therefore not amiss to notice the fact that while it is very tempting to offer a patient the great convenience of full outdoor treatment on a balcony outside his own bedroom window, this may have the serious inconvenience of preventing the full light of the sun penetrating the room below. The gallery built as a wing on one side of the sanatorium is admirably placed and is not in the way of any inhabited quarters. Yet it can be reached from the main building without leaving the cover of a roof, though the patients are in the open air.

The sanatorium is intended for the serious treatment of patients. It is not a pleasure resort and is so far from the dances, theatricals, concerts, and sports of Davos-Platz that there is no chance for reckless patients to commit an imprudence. On the other hand, the isolation is not absolute. There is some 300 yards away the "Curhaus Clavadel" with 27 bedrooms and two pensions of from six to seven rooms each, which do not profess to be sanatoriums but where the friends of patients and ordinary tourists can board for from 5*s*. to 8*s*. a day. Then there are the three or four peasants' cottages where the natives live to such a ripe old age. At the sanatorium board and medical advice, baths, douches, and massages are charged 8*s*. 10*d*. per day, but this does not include the cost of wines, mineral waters, medicines, or of the rooms. The rent of the rooms is charged separately and varies from 1*s*. 8*d*. to 5*s*. a day. Then every patient must pay 8*s*. for the disinfection of his room when he leaves. The fact that this last item is marked down in all the prospectuses is decidedly encouraging. It shows how thoroughly the necessity of disinfection is recognised and has become a part of the everyday customs and habits of the people.

Having thus said a few words concerning two well-known and typical private sanatoriums for paying patients, there remains the more complicated and more important question of the popular sanatoriums. Outside Davos-Platz, at some considerable distance and on the farthest side of the beautiful Davosersee, the Germans have established a popular sanatorium with 80 beds. In Davos itself, perhaps too near the centre of the town, is the Dutch popular sanatorium. (Fig. 3.) This, so far as the building is concerned, cannot be considered a model institution. It is not very far from the main road close to the point where Davos-Platz merges into Davos-Dorf, and though the building stands by itself with a good sized field before and behind nevertheless there are other houses close at hand. The invalids when they go out are near the main street, cafés and small taverns, and the other disturbing influences of town life. This, I take it, is not the ideal. On the other hand, there is nothing to prevent the patients enjoying the full advantages of the Alpine climate. The hills, mountains, and pine forests are close at hand, and those who have come all the way from Holland to this beautiful place must indeed deem themselves fortunate. The house is a great square building evidently not constructed for a sanatorium though it might suit as a hotel. Terraces or broad balconies have been built in front to enable the patients to lie in the open air and sunshine but there are bedrooms at the back where little or no sun can be enjoyed. Nevertheless, and reckoning this sanatorium as containing 50 patients, the cost of the building amounted to £150 per bed. The cost of maintenance is estimated at 5 fr. 56 c. (4*s*. 5½*d*.) per day. The patients are charged 4 fr. 90 c. (3*s*. 11*d*.) per day, which they pay themselves either out of their own pockets or through a benefit fund, or else by the intermediary of some charity. It will be seen, therefore, that there must be a deficit and consequently appeals for help have constantly to be made. There is but one resident physician who has, however, to see each patient at least once every day and more frequently when necessary. There are a few small rooms with but one bed but the majority of the rooms are larger and contain two or three beds. The usual diet consists of tea, milk, bread-and butter, and cheese, or some sort of porridge made with boiled milk, given at 8 o'clock in the morning. At noon dinner is served and consists of soup, meat, vegetables, a sweet dish, and dessert. At 3 P.M. there is afternoon tea or a glass of milk. At 6 P.M. supper is served, which consists of meat, bread, butter, cheese, jam or honey, with coffee and milk. At 8 P.M. more milk is given. The diet, therefore, seems plentiful and the cost of the establishment moderate.

FIG. 3.



The Dutch Popular Sanatorium at Davos-Platz.

But more interesting, and serving better as a model, is the sanatorium founded by the Society of Public Utility of Basle. (Figs. 4 and 5.) This was opened on Dec. 14th. 1896. It contains 86 beds and cost £22,642, or £263 pe bed. Here we have a vast building erected especially a a sanatorium and this on an ideal site. It is away from the town on the other side of the Davos valley. It nestle under the shelter of a pine-covered hill which supplies not only shelter but the best of exercis and close at hand. In front there is the open valley with the su pouring its vivifying rays on to the façade of the building. Here the vast terraces form arms on each side of the building that stretch out as if to embrace the light and warmth. There is no lack of room for the patients to lie out unde shelter and yet be in the open air. They will not inconvenience anyone. They are well out of sight nor will any nois or dust reach them. Of course the more healthy and stron could walk as far as the main street of Davos-Dorf or Davos-Platz and even without going that distance might find café or taverns to their liking. The patients, however, who ar to the industrial school. Of the 64 boys examined there were six with sound mouths and the remainder had an average of three decayed teeth each. It is of interest to compare these results with those found among the boys attending the public elementary schools. In the industrial school 9·3 per cent. of the boys had sound mouths while in the public schools the percentage was 3·3. The public school boys averaged 3·7 decayed teeth per boy, compared with 2·7 in the case of the boys in the industrial school. Mr. Morgan expresses the opinion that this difference is due to the fact that the boys at the latter school are less pampered than the children attending the public schools, that they have harder food to eat and thus make use of the muscles of the jaw to a greater extent, so improving the nutrition of the gums, and that they rarely have any spare cash to spend at the sweetstuff shop. In view of the fact that many of the industrial school boys will enter the army and the navy he urges the importance of a periodical examination by a dental surgeon.

Winsley Sanatorium.

At a meeting of the Bristol and Bath branch of the British Medical Association which was held at the Winsley Sanatorium on July 12th Dr. Lionel A. Weatherly gave some interesting details of the institution since the first patients were received last December. During the period indicated 57 of the 60 beds have been occupied. Altogether 85 patients have been treated and 31 have been discharged. Of the latter number seven have returned to their ordinary employment and 11 have found lighter work than they had previously been accustomed to. Eight patients were sent home without any signs of improvement, nine were very much improved, and in 14 instances the arrest of the disease was practically complete. Dr. Weatherly stated that the cases were roughly classified as (1) those in which they expected to get complete arrest of the disease; (2) those in which they might reasonably expect to get what would be practically a cure; (3) those in which they could hope for some little improvement and help the patients on for a few years; and (4) those which were unsuitable and for which from the moment they came in it was seen that little good could be done. He also spoke of the difficulty there was in finding suitable work with proper surroundings for those who had been treated in the sanatorium and suggested the formation of an after-care association for the purpose of dealing with such cases as needed to be dealt with.

Careless Conveyance of Arsenic Ore.

At the meeting of the Redruth (Cornwall) rural district council held on July 14th a discussion occurred in reference to the danger caused by the dropping of arsenic ore on the public roads from wagons belonging to a local mining company. The clerk stated that the attention of the company had been drawn to the matter but the nuisance had not been abated. It was eventually decided to invite the Redruth and Camborne urban councils to take joint action in the matter.

Taunton Isolation Hospital.

At the meeting of the Taunton town council held on July 11th a discussion took place in reference to the management of the isolation hospital. The subject has been already alluded to in THE LANCET. Eventually the council members of the hospital committee declined to serve on the joint committee with the rural district council any longer and the whole matter was adjourned pending the decision of the Local Government Board as to whether the town council or the rural district council would carry on the hospital as a single authority.

July 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The late Principal Sir William Muir.

Sir William Muir, K.C.S.I., late Principal of the University of Edinburgh, died at his residence, Dean Park House, Edinburgh, on July 11th. Until about a fortnight previously to that date he had been able to take regular carriage exercise but had latterly been confined to his bed. Sir William Muir was 86 years of age at the time of his death, having been born in Glasgow in 1819. His father, who was a merchant in that city and a member of the town council, died in 1821 and his widow with her four young sons then removed to Kilmarnock. Each of the four boys subsequently entered the service of the East India Company. Sir William Muir studied in the Universities of Edinburgh and Glasgow and subsequently spent two years in the East India Company's College at Haileybury. He then proceeded to India where he remained for 39 years. From the outset his administrative abilities were recognised and they were increasingly demonstrated as the appointments which he held became more important. As a young lad he was employed in connexion with the land assessment in Cawnpore and Bundelbund. In 1843 he was appointed to the magistracy and collectorship of Suttehpore, where he remained until 1846. During the Mutiny Sir William and Lady Muir, with some of their children, were among the Europeans shut up in the fort at Agra. After the Mutiny was subdued he became secretary to the Viceroy, Lord Canning, at Allahabad. In 1864 he was appointed a member of the Imperial Legislative Council of India and soon thereafter he became Secretary for Foreign Affairs to the Government of India. From 1868 to 1874 he held the important office of Lieutenant-Governor of the North-Western Provinces. During his rule over this district he made his influence strongly felt, especially in the departments of public instruction, sanitation, and economic progress. The Muir College and Allahabad University stand as monuments to his memory. In 1874 he became finance member of council. After holding this post for two years he retired from the Indian service, but for the following nine years he continued to work as a member of the Indian Council in London. He very much disliked the opium trade and strongly opposed the extension of opium cultivation. When the office of Principal of the University of Edinburgh became vacant on the death of Sir Alexander Grant the curators in 1885 elected Sir William Muir and for 18 years he exerted in Edinburgh the influence which intellectual ability combined with courtesy of disposition and a genuine uprightness of character is bound to produce. During his period of office various important developments occurred. The Universities Act of 1889 and the Universities Commission made alterations respectively in the constitution of the University and in the scheme of studies. Further, the Students' Union was built and the Students' Representative Council was formed. Later, by the erection of the M'Ewan Hall the University was provided with a building suitable for public ceremonial occasions. In 1902, after a period of ill-health, he intimated his resignation of the principalship and the University Court in accepting it entered on its minutes a high appreciation of the services which he had rendered in that capacity. Sir William Muir produced a number of important literary works, among which may be mentioned "The Life of Mahomet," "The Caliphate," "Mameluke Dynasty," "The Coran, its Composition and Teaching, and the Testimony it bears to the Holy Scriptures," "The Mohammedan Controversy, 1897," "The Apology of Al-Kindy," "The Rise and Decline of Islam," and "The Lord's Supper; a Witness to the Death of Christ." In recognition of his literary eminence he received honorary degrees from the Universities of Edinburgh, Glasgow, and Oxford. He also had the degree of Ph.D. of Bologna. The funeral, which took place at the Dean Cemetery, Edinburgh, on July 15th, was, in accordance with the wishes of the family, as far as possible of a private nature. The University Court, the Senatus, the Students' Representative Council, and the University Union were the only public bodies formally represented. On Sunday, July 16th, a memorial service, conducted by Professor W. P. Paterson, D.D., and the Rev. John Kelman, M.A., was held in the M'Ewan Hall under the auspices of the Students' Representative Council. It was attended by a large number of the professors of the University, by the executive committee of the Students' Representative Council, and by a large number of students.

The School of Medicine of the Royal Colleges, Edinburgh.

At a meeting of the governing board of the School of Medicine of the Royal Colleges, Edinburgh, the secretary and registrar, Mr. R. N. Ramsay, reported that the number of students attending the school during the winter session, 1904–05, was 1122 and during the summer session, 1905, the number was 1237.

University of Aberdeen: Interesting Memorials.

The portrait medallion, in marble of the late Principal with its frequent opportunities of seeing royalty both informally and in all the pomp of ceremonial pageantry, can perhaps scarcely enter into the feelings and emotions of our far-away northern towns when the pent-up loyalty of the people finds expression on the rare occasion of a Royal visit. In Manchester everything had been put aside so that full and fitting preparation could be made for showing the fervent loyalty pervading all classes of the people. Without attempting any explanation of the fact, it is as true in these democratic days as in old times that there is something in the associations surrounding an ancient reigning family which touches the imagination and the emotions; and when to this are added the respect and affection inspired by lives dedicated to the good purposes which have ever held a foremost place in the careers of King Edward VII. and Queen Alexandra, all such sentiments are deepened and intensified. The one event in the undistinguished and but too sombre lives of many of the tens of thousands who looked on their King and Queen probably for the first and last time that will never be forgotten is the glimpse they had of them on Thursday last and they will, perhaps, cherish the conviction that a smile or a bow was specially for them. It was a busy day. From the station at Hunt's Bank the procession drove up Market-street and in front of the infirmary in Piccadilly 30,000 children and more cheered and waved 30,000 flags, blue, white, and red. In Princess-street 8000 more children gave joyous evidence of their presence and in Albert-square as the King and Queen entered the town-hall the thousands of people assembled cheered again and again. Here addresses were given and responded to. Near the entrance to the town-hall 200 old soldiers of the Crimean war were drawn up. Among them were the halt, the lame, and the blind, but almost all of them marched past and saluted their Majesties as they were about to start for the Ship Canal. With half a dozen sergeants the King and Queen shook hands while "Where are the boys of the old brigade?" was asked musically by the volunteer band. Of course there were children everywhere and in front of the blind asylum there were some thousands and at the deaf and dumb school one of them who, though deaf, had been taught to speak, presented the Queen with a bouquet and the youngest child in the blind school, who was lifted up to the carriage, asked the Queen's acceptance of a "bunch of flowers" on behalf of the inmates of the blind asylum which she took with "tears in her eyes." After the ceremony of opening the new dock, said to be one of the largest in existence, the procession went on to Peel Park in Salford, where an address was presented, and at Oldfield-road, opposite the Salford Royal Hospital, the King, at the request of Colonel Sir Lees Knowles, M.P., unveiled a memorial erected by Salford to "many brave men who served their sovereign and country in South Africa in 1899-1902, and particularly in honour of the Volunteer Active Service Companies of the Lancashire Fusiliers." The next move was to the Victoria station, which was left by the Royal train at 4.45 for Knowsley. There was no hitch in the proceedings and no serious accident occurred in the seven miles of the route traversed by the Royal procession.

The Case of Plague at Manchester.

All cause of fear that the case of plague which recently occurred at Manchester would be followed by others seems now to be removed. The medical officer of health reported to the Tees port authority at a meeting held last week that on hearing of the death at Manchester he again inspected the ship in which the man who died came over and found all well. He also found the men who had been paid off and had gone into the town quite well and the inquiries he had made as to those who had gone to their homes were satisfactory. The man who had accompanied the poor fellow who died to Manchester returned to Middlesbrough wearing the dead man's silk scarf and a few days afterwards fell ill and, "showing all the symptoms of plague, was removed to the isolation hospital." Blood taken from this man was sent to London for examination and was reported free from any signs of plague. Shortly afterwards he and the others in the hospital were discharged and the ship left a day or two later for London. All on board the ship and those of the crew in the town had been removed to the hospital and a rat-catcher had cleared the ship of rats both dead and alive. These were sent to London for examination and were also reported to be healthy—i.e., free from any signs of plague.

Degree Day at the University of Manchester.

The conferring of degrees at the University of Manchester took place on July 8th in the Whitworth Hall. Lord Spencer, the Chancellor, was resplendent in Court dress with Garter and Ribbon and over it the violet gold-braided robe of the Chancellor with a violet and gold academic cap. This magnificence of attire, with "the splendid dignity of the Chancellor's entry," is supposed to have filled the students with awe as they were not so frolicsome as usual, only manifesting the spirit within them by giving a cheer when the Chancellor said he did not intend to make a long speech. The Bishop, with other members of the University Court, was on the platform, and also a distinguished American authority on education, Dr. Nicholas Murray Butler, President of the Columbia University of New York, upon whom was conferred the degree of Doctor of Laws. The passage of the Chancellor's address most interesting to the medical profession was that in which he spoke of the great scourge—yellow fever—which year after year carried off hundreds and thousands of victims in the West Indies. But now a work which can be traced directly to educational influences has been done by the American Government which has freed Cuba from the scourge, so that now it can be said that yellow fever no longer exists there. Lord Spencer was frank enough to say that he had "only this morning" heard of that great work and one wonders, therefore, whether he has heard of the self-denying and devoted labour by British workers, not by the British Government, in the investigation and treatment of tropical diseases. After receiving his degree Dr. Butler gave an eloquent address, in which he spoke of the two chief aims which he thought a university should serve in such a population as that of Manchester. "First to keep lighted the fires of letters and scholarship and to make plain that the vast material growth and expansion that we see on every hand has but added to the value of the old truths and ideals that have elevated mankind out of his barbarism to the civilisation of which we are so justly proud. ...... And next ...... to show the urban community and those depending upon it how their interests, their health, their growth, their education, and their prosperity may best be increased and furthered by the application of scientific truth and scientific method to the needs and necessities of the moment." The degree of Doctor of Medicine was conferred on the following gentlemen who were presented by the Dean of the Faculty of Medicine:—Miles Bracewell Arnold, Andrew Campbell Clarke, Mercier Gamble, Edmund Albert Goulden, John Percival Handel Greenhalgh, Charles Paget Lapage, Arthur Francis Martin, Samson George Moore, Harry William Russell, Claude William Scott Saberton, Samuel Woodhouse Thomson, and Thomas Tierney. A graduate scholarship in medicine was awarded to Thomas Wingate Todd and the gold medal among the Doctors of Medicine to Mercier Gamble and Harry William Russell. In the afternoon a garden party, largely attended, was given at Fallowfield.

Would-be Suicides.

At the Salford borough sessions the other week the Recorder stated that out of the 18 names on the calendar eight of the number were charged with attempted suicide. Family troubles, lack of employment, ill-health, and drink were the causes given for these attempts. He thought that this state of things was very serious and not creditable to the borough, while the problem of how to deal with the people was a very difficult one. In some places, both in this country and on the continent, the hot weather seems to have driven people to suicide and, of course, the accidental deaths from drowning have increased, as they usually do.

Cumberland Hospital Sunday and Saturday.

The total amount collected for the Cumberland Hospital Sunday and Saturday Funds is £1406.

July 18th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Teeth of School Children.

SOME time ago Mr. E. Rice Morgan, one of the medical officers of the Swansea education committee, prepared a report upon the teeth of boys and girls attending five of the public elementary schools in the borough (an account of this report appeared in THE LANCET of Feb. 4th, 1905, p. 328), and at the end of last June he published the results of more extended observations in the same direction applied very serious and expensive problem. Two courses are open: one is to continue to construct bacteria beds with the idea of purifying the sewage before it enters the lough, and the other is to carry a sewer down on each side of the lough for miles so as to open into the sea at the mouth of the lough. The latter is the more expensive but it is really the only thorough solution of the question.

The Central Midwives Board.

The reply given by Mr. Long, Chief Secretary for Ireland, in the House of Commons to Mr. C. C. Craig, M.P., on July 6th in answer to a question asking why the Central Midwives Board of England had refused to place upon the roll of certified midwives nurses trained at the Belfast Maternity Hospital previously to March 31st, 1905, while it had placed on this roll nurses trained under similar conditions and up to the same date at the Dublin Maternity Hospitals, at the Cork Maternity Hospital, and at the Maternity Hospital in Limerick, has excited considerable surprise in Belfast. The Belfast Maternity Hospital was not recognised, he said, owing to its failure to apply in time. Now in the memorial presented to the Central Midwives Board by the board of governors and medical staff of the Belfast Maternity Hospital it is stated: "We have been informed that our request has been refused because it ought to have been made earlier. In reply, we beg to state that the delay arose on our part owing to the building of our new maternity hospital—the largest of its kind in Ireland outside Dublin—and in reply to a letter written to the chairman of the Central Midwives Board by a member of the medical staff, asking if it would do to apply after we had entered our new hospital, he was informed in a letter dated Oct. 14th, 1904, 'If you apply when your new hospital is ready the Board will consider the matter without delay'; we entered our new hospital at the end of last year and on Feb. 14th, 1905, we made formal application, so that the argument of not having applied in time does not hold." The date up to which nurses could apply was March 31st, 1905, so that the reason furnished to the Lord President of the Council for the Chief Secretary as an answer to Mr. Craig's question is totally inaccurate. But the Central Midwives Board will now have to reckon not only with the Belfast Maternity Hospital but with the Ulster Hospital for Women and with the maternity associated with the Belfast union infirmary, the authorities of all of which are complaining at the extraordinary action of the Central Midwives Board, and at a meeting of the Council of the British Medical Association held in London on July 5th it was decided to request the Central Midwives Board to reconsider the question "so that nurses trained in the Belfast Maternity Hospitals prior to March 31st, 1905, and who present certificates of having passed the examination at the end of their practical training shall be placed in the same position as nurses trained under similar conditions in the Dublin Maternity Hospitals and in the Lying-in Hospitals of Cork and Limerick, and who, up to March 31st, 1905, have been placed on the roll of certified midwives." The Central Midwives Board is by its action in this matter raising a great deal of opposition both among the public as well as among the members of the medical profession.

The Belfast Court-house.

A proposition was adopted by the Belfast grand jury on July 17th expressing gratitude to the high sheriff (Dr. H. O'Neill) for his efforts to bring about a better state of affairs in the building, sanitary and otherwise, for the accommodation of judges, advocates, jurors, and witnesses. The Lord Chief Baron endorsed the vote of thanks to the high sheriff.

July 18th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Watering place Committee.

THE Minister of the Interior has just issued an order by which there is constituted as part of his department a permanent committee dealing with the watering places and climatic stations of France. This committee's duty will be to examine into the general needs of such places, to be, so far as it can, a body devoted to their interests, and generally to protect and to develop them. The Minister of the Interior is the honorary president of the committee. The mayors and the medical men of the various watering places, the directors and the committees of *sociétés thermales* are liable each in his turn to be summoned to serve on the committee but only for a period of three years. Extraordinary meetings may be summoned by the minister or on the demand of one-third of the members. The president of the committee is M. Armand Gautier, member of the Academy of Medicine; the vice-presidents are M. A. Carnot, inspector-general of mines; M. Cazeneuve, deputy; M. Chautemps, senator; and Dr. Lannelongue and Dr. Robin, both of whom are members of the Academy of Medicine. The secretary-general is Dr. Huchard and there are some 60 ordinary members of committee.

Municipalities and the Public Health.

At the meeting of the Academy of Medicine held on July 4th Dr. Poupinol, mayor of the commune of Saint-Arnoult, and Dr. Camescasse, a local medical man, contributed a most interesting paper showing how the public health law is administered in some districts. An epidemic of diphtheria broke out and Roux's serum was used with such success that there were no fatal cases. Of the total number of cases in which it was used 29 were undoubtedly diphtheria, nine were doubtful, and in 89 the serum was used as a prophylactic. The municipality refused to help in defraying the expenses of the treatment and the sub-prefect who in a preliminary note recommended the use of the serum, in a second note refused to procure it saying that the method was a private therapeutic method and not a means of protecting the public health. The mayor, being a medical man, was naturally annoyed and brought the contents of the note before the Academy of Medicine.

A Case of Relapse in Pneumonia.

At the meeting of the Hospitals Medical Society held on July 7th M. Antony reported the following case. The patient was a *garde républicain*, aged 29 years, who developed an ordinary pneumonia of the base of the right lung. Consolidation gradually extended upwards and forwards and the crisis arrived on the eighth day, being accompanied with polyuria. Eight days later the base of the left lung became affected and four days after this the second crisis took place also accompanied with polyuria. The patient completely recovered by the twenty-first day after invasion.

White Swelling of the Knee successfully treated without Resection.

At the meeting of the Surgical Society held on July 5th M. Walther showed a young girl who had been under his care for 18 months suffering from white swelling of the knee with almost complete backward displacement of the tibia. The patient was treated with simple extension, continued for some time together with the application of the *méthode sclérogène.* The result was eminently satisfactory, the tuberculous process being apparently quite extinguished and the patient was able to walk well with a stiff joint, the limb being quite straight. M. Lucas-Championnière, M. Arrou, and M. Routier, however, gave it as their opinion that although the result obtained by M. Walther was so good, it would have been better and quicker to have resected the knee-joint.

Sympathetic Ophthalmia.

At a recent meeting of the Ophthalmological Society M. Chevallereau reported the case of a child, aged 11 years, who six weeks after receiving a severe injury to the left eye presented marked symptoms of sympathetic ophthalmia of the right eye. The injured eye was removed and by the second day after the operation the right eye cleared up. The mercurial innunctions which had been begun before the enucleation were continued and in a very short time the eye recovered all the visual acuity which it had possessed previously to the onset of the sympathetic ophthalmia. M. Chevallereau drew attention to the two most noticeable points, first, the successive appearance at a very short interval of the two most common forms of sympathetic ophthalmia—namely, irido-choroiditis and optic neuritis, and, secondly, the complete and rapid disappearance of the sympathetic symptoms after enucleation of the injured eye.

Rabies following a Bite from a Mouse.

At the meeting of the Biological Society held on July 1st M. Remlinger of Constantinople read a paper concerning the case of a young girl who was bitten on the finger by a mouse and who died six months later from acute rabies. As the patient had never been bitten or licked by a rabid dog or cat or by one even suspected of rabies, it seemed only rational to attribute the rabies in her case to the bite of the mouse.

Sir William Geddes, by Mr. Pittendrigh Macgillivray, R.S.A., has now been completed and will during the vacation be placed in the recess reserved for it in the Geddes transept of the library at King's College. The medallion is an admirable work of art and the likeness is very striking. The sole inscription consists of the words "William Duguid Geddes" and the last line of the eleventh book of the "Odyssey" in the original Greek (suggested by Lady Geddes as a saying which the late principal delighted to quote as an incitement to his students). The translation of the line is: "First the toil at the oar and then the favouring breeze." The medallion will probably be unveiled at the opening of next winter session. At the same time the memorial to the late Professor John Fyfe will, it is hoped, be in position. This consists of a design by Mr. Douglas Strachan to be placed in one of the windows of the King's College library. The design symbolises bibliography, being one of a series suggested by Mr. Strachan to fill the seven main windows in the south side of the library and to represent theology, philosophy, literature, mathematics, fine arts, &c. The only lettering, in addition to the dedicatory inscription, consists of the verse from Proverbs, "Wisdom hath builded her house; she hath hewn out her seven pillars." A meeting of the committee having charge of the proposed memorial to the late Professor James Nicol was held in Marischal College on July 15th, Professor J. W. H. Trail being in the chair. Dr. William Mackie (Elgin), the honorary secretary, read a large amount of correspondence with geologists and old pupils of Professor Nicol, the general tenor of which favoured the placing in the geological museum of a portrait tablet in bronze, similar to those recently erected in memory of Professor Macgillivray and Professor Alleyne Nicholson. The amount received is nearly sufficient to meet the cost of such a tablet, and it is hoped that a few additional subscriptions will be intimated to Dr. Mackie before it is necessary to close the list. The committee aims at a formal inauguration of the memorial during the quater-centenary ceremonies next year, when many pupils of Professor Nicol will be in Aberdeen.

The Cost of Kingseat Asylum, Aberdeen.

The following is a statement of the payments to contractors and others up to date in connexion with the Kingseat Asylum. I send you these details because the figures in relation to the Kingseat Asylum are often quoted.

	£	s.	d.
Purchase of lands and cost of improvements, &c.	12,428	1	1
Improvement of ground	2,267	5	5
Mason	27,742	6	10
Carpenter	17,933	4	1
Plumber	7,017	11	1
Slater	2,689	5	0
Lath, plaster, and tile work	6,370	0	0
Painting, glazing, and papering...	2,704	5	7
Iron, smith, and founder work	2,810	7	10
Heating and ventilating	6,827	17	2
Architect and clerk of works	4,997		6
Draining, fencing, &c.	2,01	4	1
Waterworks...	4,789	10	10
Roads	2,449	5	7
Electric installation	5,786	3	0
Sewage purification works	1,889	4	1
Laundry machinery and cold storage plant	2,844	10	0
Household furnishings	183	8	10
Ironmongery and cutlery	477	15	4
Bed-coverings	1,934	0	11
Table linen and towelling	220	6	9
Mattresses and upholstery	1,148	1	3
Carpeting, floorcloth, &c.	651	2	11
Joiner and cabinet work...	4,523	3	4
Stoneware and glass...	142	3	7
Minor furnishings	1,580	16	6
Payments to others than contractors, including salaries of officials and preparing buildings for occupation	910	17	9
Total	£125,335	19	4

The accounts for the year show that there were paid for interest on loans £4002 18*s*. 9*d*.; instalments of sinking fund, £3893 11*s*. 5*d*.; taxes and assessment, £379 19*s*. 10*d*.; repairs and upkeep of the asylum buildings, £250 4*s*. 1*d*.; printing, &c., £178 0*s*. 5*d*.; and office rent, £60; making with other payments a total of £9207 13*s* 8*d*. In the farm account for the year there is a deficit of £586 17*s*. 9*d*., and in the general account the deficit is stated to be £2862 18*s*. 6*d*. The maintenance of patients and expenses came to the substantial sum of £10,993 16*s*. 3*d*., the chief items being the following: butcher's meat, £638; milk, £616; butter, £220; bread, £573; clothing, £2036; boots and shoes, £338; fuel, £1409; salaries and wages, £2588; carriage of articles and conveyance, £297; and incidental expenses, £217. In the estimates for the coming year the cost of maintenance is put down at £10,807 0*s*. 5*d*., which with the debit balance for last year of £2862 18*s*. 6*d*. makes a grand total of £13,669 18*s*. 11*d*. It is estimated that the number of patients for the coming year will be 390 and that the average cost of maintenance per annum will be £35 1*s*.

July 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Serious Illness of Sir Antony Macdonnell.

THE Under Secretary, Sir Antony Macdonnell, has been suffering for some weeks. On Saturday, July 15th, he was removed from the Chief Secretary's Lodge in Phœnix Park and conveyed by an ambulance to the private hospital in Tower Mount-street where an operation was performed by Sir William Thomson. The bulletin of this evening, July 18th, states that the patient's strength is well maintained and his progress satisfactory. Telegrams of inquiry have been received from the King and also from the Pope.

Professorship of Chemistry to the Apothecaries' Hall.

The position of professor of chemistry to the Pharmaceutical Society's School of Ireland has just been filled by the appointment of Mr. P. Kelly, M.P.S.I., Dublin. He was formerly lecturer in pharmacy at the Ledwich School of Medicine and has since devoted his time to the study of pharmaceutical chemistry. He now succeeds the late Professor Tichborne, LL.D., L.R.C.S. Irel., who was long well known to the medical profession in Dublin as president of the Royal Pharmaceutical Society of Ireland, Government analyst for many counties, and for some years member of the General Medical Council.

Death of Mr. W. Duncan, L.F.P.S. Glasg.

Mr. William Duncan, who for the past 14 years has been in practice in Belfast, died on July 11th after a lingering pulmonary illness. He was only 46 years of age and owing to his skill, genial disposition, and sympathetic nature he enjoyed a large practice among the working classes of Belfast. He leaves a widow and family. He was buried in Castledawson, Co. Derry, on July 14th.

Health of Belfast.

At a meeting of the public health committee held on July 13th considerable discussion arose as to the high death-rate for the week ending July 8th, which was from all causes, 18·9, the highest amongst the great cities of the kingdom; and from the principal zymotic diseases, 1·9. This high death-rate was ascribed to irregular registration of deaths and the usual weekly fluctuations. For instance, in the week ending June 24th the death-rate from all causes was 12·6 (the lowest in Ireland), whereas it jumped up to 17·6 and 18·9 respectively in the two weeks following. Taking into consideration the nature of the occupations of the people, the medical officer of health contended that the health of Belfast was fairly satisfactory.

The Foreshore Nuisance in Belfast Lough.

The Select Committee of the House of Commons, after hearing evidence, decided on July 14th to confirm without any modification the provisional order made by the Local Government Board, under which a joint board is formed, representative of Belfast, Castlereagh, and Holywood, to prevent the pollution of Belfast Lough by sewage and decaying seaweed. There is a general feeling that the Belfast corporation would have been wiser not to have opposed the scheme; and as a result it has gained nothing but has spent a large amount of the ratepayers' money in a useless piece of opposition. The fact of the matter is that with the constant discharge into Belfast Lough of the sewage from 270,000 inhabitants it is rapidly becoming little better than a vast cesspool. This year, with such exceptionally warm weather on both sides of the lough, the stench is far worse than ever and is being felt at an even greater distance down the lough than before. The inhabitants on both sides of the lough are complaining more than ever and as a result the Belfast corporation is faced with a

The long incubation period (six months) and the long duration of the attack (nine days) pointed to the inoculation of a very small quantity of virus and not to its attenuation by passage through the mouse. Both rats and mice are very susceptible of the poison of rabies and possibly bites from them may explain the so-called spontaneous cases of rabies which have been observed both in men and in animals.

The Heredity of the Stigmata of Degeneration in Reigning Families.

M. Galippe has been carrying out a research into this subject and he chose reigning families because their archives are complete for several centuries and not because they have an exclusive privilege in degeneration. Among them he fixed upon the house of Hapsburg because this family possesses one stigma which is easily observed and which, moreover, is transmitted not merely in the Hapsburg line proper but in families allied with it. The stigma in question is prognathism of the lower jaw, together with certain secondary anomalies which accompany it. By the aid of illustrated documents which he criticises M. Galippe has been able to trace the hereditary transmission of this stigma of degeneration from the fifteenth century up to our own times. He notes that the female side is chiefly concerned in this transmission and gives historical examples, such as that of the King of Rome who was a Hapsburg, both from the physical and the moral point of view. Founding his contention upon the heredity of certain characteristics of physiognomy M. Galippe proves the pedigree of Don John of Austria, natural son of the Emperor Charles V., as well as the legitimacy of the claims of the pseudo-Louis XVII., *alias* Naundorff. M. Galippe communicated his work to the Academy of Medicine on July 4th.

The Course of Medical Study.

The Minister of Public Instruction has just sent out to all University Rectors a circular relating to medical studies. After referring to the fact that medical studies have been for some years past the target for lively criticisms the minister points out that the technical studies of the future medical practitioner are on an assured basis but that their professional training does not seem sufficiently practical. It is of little use simply to acquire a mass of information; those about to enter the medical profession should have a taste for observation of such a kind that they will be fitted to act with decision and prudence in the many very responsible circumstances in which they may find themselves. The minister makes a special recommendation that the chief place should be given to the practice of medicine during the stage of hospital work. He suggests that the rectors should have a consultation on the subject with the Faculty of Medicine attached to their respective jurisdictions (*ressorts*). Finally, he asks whether the present system of examinations shall be retained, whether the examinations at the end of each year shall be re-established, or whether they shall be grouped at the end of the third or of the fourth year. The minister requests that answers to these questions may be sent to him before Jan. 1st, 1906.

Painful Mastitis: Operation by the Æsthetic Method of Morestin.

At the meeting of the Society of Anatomy held on July 7th M. Péraire showed a mammary tumour, a pure fibroma. He had removed it on account of the pain to which it gave rise, this pain being more acute at each menstrual period. The patient's age was 23 years and she had noticed the growth for about a year. It had no connexion with lactation nor was there any history of injury. The growth was apparently continuous with the gland substance. M. Péraire employed the axillary incision of Morestin by which the shape of the breast was unaffected.

July 17th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Practitioners' Association.

THE annual meeting of the German Practitioners' Association (*Deutscher Aerztetag*) was held on June 26th and 27th at Strasburg in Alsace, Professor Loebker of Bochum being in the chair. The principal subject of discussion consisted of questions connected with the medical academies, to which I have referred on a former occasion. These academies, which are attached to the hospitals of the larger towns, will supply practitioners with opportunities for post-graduate study and will facilitate the training of specialists. Students may also be admitted to the academies for their "practical year," in accordance with the new regulations relating to medical examinations. Hitherto only one academy has been opened—namely, at Cologne, but it is the intention of the Government to establish similar institutions in other towns also, Düsseldorf and perhaps Frankfort being the next places chosen for that purpose. The creation of the academies has from the beginning met with the disapproval of the medical profession for several reasons. First, because the whole question was settled without opportunities for discussing it being given to the official representatives of the profession; and, secondly, because the aims and the work of the academies were undisclosed except for vague rumours which found their way into the newspapers. A further difficulty was that not only the medical profession but also certain political combinations looked askance at the projected institutions, fearing that the Government might then have an opportunity to interfere with the administration of the municipal hospitals and the appointment of the medical officers and might in that way encroach on the powers up to that time exercised exclusively by the local municipal authorities. The apprehensions expressed previously to the establishment of the academies proved to be well founded in the case of the academy at Cologne. Apart from the above-mentioned objections, the medical profession of Cologne felt it to be a special grievance that out-patient departments on a large scale were attached to the academies and took away patients from the local practitioners. Moreover, the fact that several assistantships were reserved for members of the Army Medical Corps was much opposed, the same being the case with certain professors of the neighbouring University of Bonn who were appointed lecturers to the academy and went regularly several times a week to Cologne to deliver lectures and to perform operations. The medical societies of Rhenish Prussia and Westphalia therefore passed resolutions against the academies on several occasions and it was by their representatives that the matter was brought before the meeting of the Practitioners' Association. In order to mitigate this hostility representatives of the Government declared a few days ago at a meeting of the Association for Post-Graduate Study that no other medical academies would be established without the approval of the medical profession and that no further steps would be taken until experience had shown the nature of the results obtained in the academy at Cologne. Notwithstanding these declarations the matter was fully discussed by the Practitioners' Association and the objections alleged against the academy at Cologne were explained by the local representatives. The meeting eventually, by a large majority, adopted a proposition moved by Dr. Mugdan, a member of the German Parliament, to the effect that the academies were not well adapted for the purposes of post-graduate study which had hitherto been undertaken by the spontaneous initiative of the medical profession; that they would prejudice the interests of the medical profession; and that for those reasons the meeting disapproved of any further creation of such academies. The other subjects discussed before the meeting were of minor interest and concerned unqualified practice, sick clubs, and the support of invalid members of the profession and their families.

Professor Koch in South Africa.

A letter written by Professor Koch to a friend and published in the German newspapers gives some particulars of the work on which he is now engaged. He is at present in South Africa and writes from Fringa in Ubebe that he has succeeded in discovering the origin of the tsetse-fly disease from which many cattle die on their way from Ubebe to the coast. He has not only found trypanosomes within the tsetse-fly but has also ascertained that these parasites undergo therein a peculiar development. Professor Koch describes the climate of Ubebe as very healthy and fit for European colonisation. The air is bracing and cool, somewhat suggesting that of the Alps and Norway.

The Effects of Smoke on Firemen.

Some interesting facts are stated in the recently published report of the chief medical officer of the Berlin fire brigade. A great number of the men suffered from the effects of the inhalation of smoke, an affection which is especially prejudicial owing to its long duration, its sequelæ including neurasthenia and cardiac neurosis. Of the men discharged with a retiring allowance one-third suffered from symptoms due to this cause. In addition to the ordinary effects of smoke, fires in chemical works were especially dangerous to the health of the men. In several instances fire broke out in celluloid factories where fumes containing prussic acid developed, leading to syncope and myocarditis among the men. In 1897, when the extensive premises known as the Schering Chemical Works were consumed by fire, serious effects were produced on a large number of men, including the chief officer who recently died from myocarditis.

July 17th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Is Enough being Done for the Sufferings Caused by the Epidemics of Plague in India?

MANY sections of the Anglo-Indian as well as the home press have drawn attention to the apparent want of policy in regard to the plague in India and to the small amount of relief in any form which is offered to the people. The Secretary of State simply reflects the views of the Government of India when he says: "It is not the case that in combating plague the Government of India is without a policy" but it is the Government of India which is blamed for not doing more. It is said that "every practicable measure that gives prospects of success and that is not utterly opposed to the habits and the sentiments of the people has been, and will continue to be, tried." The facts of the case, however, are that at the present moment all the provincial governments in India are carrying out a policy of *laissez-faire*. There are no compulsory removal to hospital, no segregation of "contacts," little or no restriction of movement of patients from one place to another, only in a few out-of-the way districts any attempt at evacuation of infected premises, and no inducements offered to take advantage of the benefits of inoculation. In a few towns the local authorities have done what they could to effect a destruction of rats (but this has never been a Government measure) and hospital treatment has been given to those who seek it. The only measure which can be said to be in force is disinfection and this is carried out in different parts in very various ways and it is very doubtful whether it is of any value at all. The Plague Research Expedition is said to be supplemental to the medical organisation already existing in India and is in no way to supersede it. The Government might well be asked, What research concerning plague is being done in India? The manufacture of the prophylactic cannot be called research and the medical profession would like to know where experiments are being made and who are doing them. Nothing original has been published for years in India and all our latest information concerning plague comes from abroad. The Government in its communications quotes Hong-Kong, Natal, Sydney, and other places where a few cases of plague have been sufficient to base valuable experiments upon and yet India, with 1,000,000 deaths in the year, has contributed nothing. The real truth is that the Government has not chosen the right men or enough men for research work and even with regard to treatment it has been left to individual practioners to purchase serum from Paris. All plague measures have lapsed.

A Parsi General Hospital for Bombay.

For some years past a general hospital for Parsis in Bombay has been talked about and now the scheme has been revived. It is proposed to begin in a modest way by renting a building and converting it and as funds come in to extend or to rebuild it. It is estimated that three lakhs of rupees (£20,000) will be necessary for a commencement and that four lakhs of rupees will be required for an endowment. For this 40 patients could be treated. To equip a hospital for 100 patients would cost eight and a half lakhs of rupees. I have had from time to time to speak favourably of the Parsi Lying-in Hospital in Bombay and I feel sure with the medical reputation of the Parsi physicians and surgeons that a general hospital would prove a success.

The Small-pox Hospital Scandal in Bombay.

The Bombay small-pox hospital scandal has brought an official inquiry and an order for reform. The physician in charge attempted to traverse every item of complaint and practically would not admit that anything was wrong. The acting surgeon-general, however, admits a large number of makeshifts and want of comfort for the sick and the Government has resolved that although the complaints were exaggerated there were defects which might have been prevented by closer supervision and has ordered that the deficiencies in equipment should be immediately supplied. The outbreak of small-pox doubtless proved a great strain on the system of hospital administration and perhaps funds were served out niggardly but the Government resolution and the statement of the officiating surgeon-general that "much could have been done to have made the place neater and more orderly" show that the management of the institution was at fault. There is one point I must allude to with regret. The Government, in publishing the correspondence, has thought fit to omit No. 6 paragraph of the officiating surgeon-general's conclusions. The obvious inference is that it contained an important justification of the complaints which have been made or that it reflected upon the conduct of some particular individual.

June 30th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Bubonic Plague.

THE plague continues in New South Wales, though Dr. J. Ashburton Thompson, President of the Board of Health, is of opinion that the outbreak is nearing its end because no plague-infected rats have been caught in Sydney since May 4th. 53 cases have occurred in New South Wales since March 16th, distributed as follows: Sydney, 16; Newcastle, 12; Clarence River, 12; Lismore, nine; and Ballina, four. The last reported case was at Newcastle. In Queensland several cases have occurred in or near Brisbane and at Ipswich. The New South Wales Government has imposed stringent restrictions on fodder from Queensland. A public meeting was held in Brisbane to object to these restrictions and it urged the Government of Queensland to take action. In consequence of representations on the subject from the Premier of Queensland the Premier of New South Wales agreed that the President of the New South Wales Board of Health should visit Brisbane and discuss the matter with the Queensland authorities.

Dengue in Queensland.

The epidemic of dengue in Queensland is diminishing. The report of the Government statistician stated that there were 63 more deaths in Brisbane last month than in the same month last year and that the epidemic of dengue was largely responsible for the increase, having directly caused 39 and hastened the end of a number of persons suffering from chronic affections.

Cerebro-spinal Meningitis.

Two sporadic cases of cerebro-spinal meningitis have been reported in Victoria, one in Bendigo and one in Castlemaine. The latter proved on investigation to be an ordinary case of traumatic meningitis.

Vital Statistics of New South Wales.

The Government statistician has furnished a preliminary statement of the vital statistics of New South Wales for the year 1904. The increase of population during the year was 29,869, of which 23,307 was due to excess of births over deaths. The deaths during the year numbered 15,360, equivalent to a rate of 10·62 per 1000 of the population, which is 1·07 below the mean rate for the last ten years, and is also the lowest rate on record, this pleasing state of affairs being almost entirely due to the decrease in the number of deaths from diseases to which young children are particularly liable. The number of children under one year of age who died was 3187, equal to 82 per 1000 births. To this the metropolis contributed 1300, or 98 per 1000 births, and the remainder of the State 1887, or 74 per 1000 births. This is the lowest rate of the last ten years and is nearly 25 per cent. below the mean. The effects of illegitimacy on infantile mortality will be seen when it is explained that of children under one year the death-rate for illegitimates is nearly three times larger than that for legitimates.

Hospital Affairs.

The twenty-fifth annual meeting of the supporters of the Sydney Hospital for Children, now called the Royal Alexandra Hospital, was held on May 22nd. The report stated that during the year 619 cases were treated at the institution, with a mortality of 8·8 per cent. In the out-patient department at Valentine-street the work was stated to be increasing rapidly and the time is not far distant when another storey will have to be added to the present building. In this department there were 27,481 cases treated, as compared with 15,638 the previous year. In the diphtheria cottage 154 patients were treated. It is expected that the new building will be completed by the middle of next year. —The committee of the Melbourne Hospital has decided to reopen a ward, once used as a lock ward, for female surgical cases. It was stated that the cost per bed of these additional beds would be only £35, as against £70, the average cost per bed in the institution.—The authorities of the infectious diseases hospital at Melbourne have decided to erect temporary tents to accommodate cases of measles, an epidemic of this disease prevailing just now in Melbourne.

Patent Medicines.

A meeting was recently held in Sydney, convened by the Manufacturing Chemists' and Proprietors' Association, to protest against the revised regulations issued by the New Zealand Government with regard to patent and proprietary medicines. The chairman reviewed the New Zealand legislation affecting manufacturing chemists. An Act of Parliament had been passed that would have a far-reaching effect. Patent and proprietary medicines were dealt with in the Health Act and it contained two clauses to which strong exception was taken. The first was that the formula had to be printed on the bottle of all patent and proprietary medicines; the other was that if the contents contained an infinitesimal portion of poison it had to be labeled accordingly. In consequence of strong protests the change as to the formula had been modified, and instead of being printed on the bottle it was to be lodged with the health department. The manufacturers did not intend to conform to this modified regulation. The formulæ represented the goodwill and firms who had spent thousands of pounds in building up a trade were not going to give up their goodwill in such a light manner. They would withdraw their medicines from New Zealand and their agents in New South Wales who did a large trade would suffer. The following motion was carried:—

> That, as the modified regulations concerning patent medicines in New Zealand will tend to lessen the amount of business done by residents in New South Wales with New Zealand, this meeting protests against the same coming into force.

Assurance on Infantile Lives.

At the annual meeting of the Australian Mutual Provident Society the president stated that the society was hampered in its operations by the fact that assurance on infantile lives was at present illegal within the Commonwealth, although it was the only country in which that disability existed.

The Burial System in New South Wales.

The city coroner for Sydney recently ordered the exhumation of the body of a child and said his "object in holding an inquest in the case was to disclose a serious defect in the burial system of the State." A document, he continued, purporting to be a statement by a midwife that a child has been stillborn, is handed to an undertaker. He buries, as a matter of course, without prior or subsequent registration, and there the matter ends. The law does not require him to verify the document in any particular, and as a matter of practice he does not do so, and for all he knows the statements therein may be absolutely false and have emanated from the most disreputable person in the community. In the case investigated a premature child died soon after birth, the mother gave a certificate that it was stillborn, on which the body was buried. The necropsy showed that the child died from failure of respiration which had not been sufficiently established. A verdict of "Death from natural causes" was returned.

The Value of Alcohol.

Dr. T. H. Fiaschi of Sydney gave evidence before the Tariff Commission recently in the dual capacity of surgeon and *vigneron*. He stated that alcohol was a valuable stimulant and that good Australian wines helped digestion. He would be sorry as a medical man to have to dispense with the use of spirits. The brandy used in disease should be pure, from grape juice. He never prescribed whisky.

A Medical Man charged with Drunkenness.

At the Castlemaine police court recently a middle-aged medical man was charged with being drunk and disorderly. He was discharged on promising the bench to look after himself in future. He explained that he had been kept without sleep and rest from overwork and worry and drink was not altogether responsible for his condition.

June 5th.

Obituary.

MAJOR-GENERAL PETRONIO COSTETTI.

IT is not often that romance and hard work are so intimately blended as in the long professional career of this eminent army surgeon. Born in Bologna in 1819 he had, with his family, to migrate to Florence in 1831—the year in which many of the Bolognesi, the Costettis included, were compromised in the abortive revolution. At Florence he began his medical studies and took his degree, *summâ cum laude*, at Pisa. In 1848—another year of revolution—he served in the *guarde mobile* of Tuscany under the Marchese Niccolino Antinori and saw some sharp fighting at Montanara. We next find him an army surgeon in the Tuscan forces, espousing the Liberal cause and attending the meetings of the party in the Florentine Casa Bartolommei. It was he who, on the historical 25th of April, gave clandestine shelter in his quarters in the fortress Belvedere to the Marchese Ferdinando Bartolommei who wanted to know how far he could count upon the coöperation of the officers in the pacific revolution, two days afterwards successfully consummated. On the eventful morning the Tuscan archduke proceeded from the Pitti Palace to the *fortezza*, thence to give orders to bombard the city, but only to receive from the officers the reply that while ready to protect the lives of their princes, they could not serve the anti-national cause. While the *pourparlers* were in progress young Costetti ordered some green curtains to be taken down from the windows of the hospital in the *fortezza* and adding to them the Tuscan colours, red and white, he hoisted the improvised "tricolor" on the terrace of the *fortezza* before the eyes of the grand duchess who, in needless panic, had taken refuge in that stronghold. It was that banner which announced to the people, assembled not many yards off in the Piazza dell' Indipendenza, that the Tuscan revolution, peaceful and bloodless, was a *fait accompli*.

Dr. Costetti, continuing his career as an army surgeon, with the rank of captain, took part in the campaign against Austria in 1859. Promoted again for distinguished services in 1862 he rose to be major-general and was appointed director-in-chief of the great military hospitals of the now united kingdom. Of late years advancing age had constrained him to give up professional work but he still placed his powers and energies at the disposal of his fellow citizens of Bologna, where he had resumed residence, and as communal councillor and assessor on the board of hygiene he wrought many salutary innovations on the backward equipment of the city, the improved drainage being one of his many contributions to its sanitary provisions. Till within two years ago he was the life and soul of the Spedale della Vita for Bolognese youth and maintained to the last his interest, and where possible his coöperation, in rehabilitating the health conditions of the "mother city of universities." At 86, a youthful spirit, reflected in a fresh, even florid, complexion and a prompt, not to say brisk, address, made him as popular as he was familiar among his compatriots who all showed something of personal loss when on the evening of June 30th he passed peacefully away.

DANIEL MURPHY, M.B., B.CH., B.A.O., R.U.I.

IT was with sincere regret that members of the medical profession in Cork learned that Dr. Daniel Murphy died on July 6th at one of the seaside resorts in the neighbourhood of the city. He received his medical education at the Cork Queen's College and took his degrees at the Royal University in the year 1893. Soon afterwards he was appointed resident physician to the Cork Fever Hospital where he discharged his duties to the entire satisfaction of the committee and patients. Whilst occupying that position he unfortunately suffered from an attack of appendicitis which necessitated operation but apparently he made a good recovery. Afterwards he was appointed house surgeon at the Cork North Infirmary but held the position only a short time, as he was elected to the more important post of physician to the Cork City Dispensary. About this time his health commenced to fail and his medical advisers *recommended him to go to* a sanatorium at Nordrach. Hopes were entertained at first but pulmonary tuberculosis steadily did its work. Feeling that his end was at hand he hurried home and arrived only about a week before death put an end to his sufferings. In the earlier days of "the Battle of the Clubs" Dr. Murphy was a very regular attendant at the meetings of the profession. Though a young man he held and expressed very decided views, but always with the greatest courtesy, and he was rightly regarded by his colleagues as a most loyal and zealous champion of the interests of the profession. The time of the arrival of his funeral in the city was quite uncertain but nevertheless a large number of his medical brethren assembled to pay a last tribute to one who during his all too short life did much to maintain the honour and dignity of the profession and whose amiable and genial disposition had endeared him to all who had the privilege of knowing him.

Medical News.

UNIVERSITY OF LONDON.—At examinations for the D.Sc. degree in the Faculty of Science the following candidates were successful :—

[illegible]: Ida Smedley, Central Technical [illegible] William Horace Sodeau, Davy Faraday [illegible]ivate study.

[illegible] David Ellis, University of Marburg and Lister Institute of Preventive Medicine.

Geology.—External student: Felix Arthur Clair Oswald, B.A., private study.

UNIVERSITY OF EDINBURGH.—The following candidates have passed the examination in clinical medicine for the degree of Doctor of Medicine :—

W. Anderson, H. E. Arbuckle, Mary S. Arbuckle, C. M. Begg, R. A. Belilios, A. J. Brock, Alfred Brown, R. A. Chambers, O. H. Chapman, K. J. S. Clark, H. L. Cumming, Henry Curwen, J. M. Darling, H. S. Davidson, James Davidson, G. A. Davies, J. L. Dick, J. M. Dupont, A. N. Fell, Robert Gibson, Sidney Gilford, Archibald Gillespie, J. M. Graham, W. W. Greer, A. A. Hall, William Hamilton, P. W. Hampton, P. A. Harry, C. H. Houghton, A. M. Hutchison, R. W. Johnstone, I. C. Keir, G. F. S. Landon, A. J. Lewis, James Lochhead, R. J. M'Clelland, J. C. M'Conaghy, J. P. M'Gowan, William M'Lachlan, R. M. White Manwaring, C. A. Mayne, G. R. Mill, L. S. Milne, C. R. P. Mitchell, R. C. Monnington, F. W. More, Ernest Muir, W. H. Nutt, A. H. Pirie, J. J. H. Pirie, H. S. Reid, C. M. Richardson, H. M. Roberts, J. K. A. Robertson, S. M. Ross, D. J. Scott, S. R. Sibbald, A. B. Slater, E. W. Smyth, R. A. L. van Someren, F. S. Stanwell, D. A. Stewart, H. A. Stewart, W. Ward Smith, D. P. D. Willie, and F. A. Willie.

UNIVERSITY OF GLASGOW.—The following candidates have passed the fourth (final) *professional* examination :—

M.B., Ch.B.—Andrew Blair Aitken, §George Allison Allan, William Smith Allan, §Andrew Allison, Andrew Woodroffe Anderson, John Bain, M.A.; Annie Agnes Baird, M.A.; †James Henderson Baird, B.A.; Hugh Barr, Andrew Farm Bell, Ethel Lily Chapman, *Jeannie Thomson Clark, Robert Wilson Dale, M.A.; David William Davidson, Robert Scott Dewar, M.A.; Hugh M'Millan Donaldson, Allan Campbell Douglas, §John Shaw Dunn, M.A.; Eric John Dyke, Hamilton William Dyke, Alexander Burns Ferguson, Mary Theresa Gallagher, William Gilchrist, William Harold Gillatt, William Macmillan Gilmour, Joseph Glaister, Louis Leisler Greig, William Grier, Alexander Roberstson Forrest Hay, James Waugh Hay, Ralph Vincent Howell, John Moonette Huey, James Hunter, Harry Stewart Hutchison, B.Sc.; §Arthur Innes, §William Boyd Jack, Arnold Ernest Jones, Robert Dallas Kennedy, William Love Kirkwood, Alexander Leggat, George Hugh Logan, William Jamieson Logie, John Bertram M'Cabe, Walter George Macdonald, M.A.; Duncan M'Ewan, ‖Hugh Allan Macewen, Robert Maxwell Macfarlane, James Denniston Macfie, Milne M'Intyre, John M'Millan, *Peter Maguire, William Blair Morton Martin, Robert [illegible] Frank Andersor[illegible] Macdonald Munro, Henry Sherwo[illegible], David Penman, Thomson Rankii[illegible] Rankin, Thomas [illegible]n, William Rolland, Alexander Cappie Russell, Frank Donald Scott, Jane Reid Shaw, Lily Smellie, James Alexander Somerville, Arthur Anderson Stewart, Daniel Stewart, §John Logan Stewart, M.A.; William Alexander Stuart, Joseph Roderick Sutherland, Elizabeth Taylor Talbert, §John Taylor, William Lind Walker, M.A.; Robert Wallace, Alexander MacMillan Watson, Archibald Crombie West, and Archibald Simpson Wilson.

Passed with distinction: *In surgery and clinical surgery and practice of medicine and clinical medicine; † in surgery and clinical surgery and midwifery; ‡ in surgery and clinical surgery; § in medicine and clinical medicine.

UNIVERSITY OF ABERDEEN.—The following candidates have been successful in the examinations indicated :—

First Professional Examination.—William Allan, William Balenoch, David M. Baillie, John A. Beattie, William Chapman, J. G. Christie, Robert G. Davidson, Arthur H. Duckett, William Duguid, James Elder, G. C. Grant, John Inkster, Harold G. R. Jamieson, John Johnston, John A. Macarthur Clement R. MacLeod, Norman Macphail, Frank S. Maxwell, G. S. Melvin, Robert J. Merson, Herbert S. Milne, John Mitchell, A. D. Reid, Finlay G. M. Ross, Arthur C. L. Smith, Herbert A. Smith, W. L. Stephen, Francis W. Stuart, John K. Thompson, Charles C. Twort, John T. Watt, Alfred J. Williamson, and Alexander Wilson.

Portion of the First Professional Examination.—Hugh G. Bruce, G. P. Burr, Joseph P. Cameron, Robert M. Chance, James Conner, Ernest W. H. Cruickshank, Henry Duguid, Robert W. Eddie, James R. G. Garbutt, Thomas C. Halley, Robert Kellas, Charles A. Macdonald, Allan J. Macleod, John M'Pherson, A. Mitchell, Robert W. S. Murray, Donald O. Riddel, John Ritchie, Arthur C. M. Savege, G. E. Scroggie, Henry E. Shortt, Colin F. Simpson, Ronald Sinclair, William Smith, and David J. S. Stephen.

Second Professional Examination.—Thomas Clapperton, James A. Davidson, Thomas Donaldson, James Leask, George H. C. Lumsden, William J. Mackintosh, John F. MacLeod, James M. M'Queen, John P. Mitchell, A. E. C. Myers, Patrick Nicol, Alfred J. Pirie, David E. Rae, James Robertson, Robert W. A. Salmond, Arthur Shepherd, Alexander Stewart, John P. Stuart, James E. G. Thomson, Ernest Walker, and William A. Watson.

First Portion of the Second Professional Examination.—Robert W. Chalmers, Stephen Goodbrand, James A. Hendry, William Mearns, James A. Milne, Douglas Porter, George E. Shand, and Walter R. Stephen.

Third Professional Examination.—Francis J. Browne, Theodore Chalmers, George Cooper, James Donaldson, Herbert W. Glashan, Theodore G. Gray, R. M. Gunn, George P. J. Hendry, Adam Johnston, James Laing, James M. MacDonald, John G. M'Gregor, Stanley W. Munro, Alexander Robertson, George L. Ress, Henry Smit, John R. Stewart, and Arthur G. Troup.

Final Professional Examination.—James M. Adams, William Campbell, Alexander M. Donaldson, Robert R. Duncan, Richard Eager, William M. Ferguson, George J. Forgie, Reginald A. Forster, Charles B. Gerrard, George Hall, Alexander W. Laing, James M'Intosh, James Mackenzie, Kenneth Mackinnon, George Milne, John A. Milne, Harry R. Neilson, Paul B. Roth, Robert F. Russell, James Silver, Charles M. Smith, John H. Stephen, Isaac F. B. de Villiers, Frederick H. Welsh, Cristina Wilson, and Douglas A. Wood.

TRINITY COLLEGE, DUBLIN.—At the medical scholarship examination held in Trinity term the following awards were made :—

Anatomy and Institutes of Medicine.—William Pearson, Trinity College Scholarship, and Robert E. Wright, Stewart Scholarship.

Physics, Chemistry, Botany, and Zoology.—Richard P. Hadden, Trinity College Scholarship, and Hugh R. M. Ferguson, Stewart Scholarship.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a meeting of the President and Fellows held on July 14th Sir Richard Douglas Powell, Bart., K.C.V.O., M.D., President of the Royal College of Physicians of London, was unanimously elected an Honorary Fellow of the College. At the same meeting Dr. David J. O'Connor was admitted to the Membership of the College and the licence to practice in midwifery was granted to Dr. Stephen Garvin.

INFANTILE MORTALITY.—In order to lessen the heavy infantile mortality which inevitably occurs every summer that is at all hot, the committee of the Hospital for Sick Children, Great Ormond-street, has been accustomed to set aside an extra number of cots in each ward for the reception of children under the age of two years. This year, in addition to the usual number provided in this manner, the committee has decided to open an entire ward for children of an age liable to be attacked by a prevailing summer epidemic. The committee has just received a timely donation of 100 guineas from the Worshipful Company of Mercers.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors was held on July 12th, Mr. Christopher Heath, the President, being in the chair. 12 directors were present. One death and one resignation had occurred among the members since the last court. Three new members were elected. The death of a widow was reported who had been an annuitant of the society since 1886 and had received in grants the sum of £1063 5*s.*; her husband had paid £52 10*s.* in subscriptions. An application for relief had been received from a widow of a deceased member and a grant at the rate of £50 per annum was voted. 53 widows and 16 orphans are now in receipt of relief, the total sum for the half-yearly grants being £1324. The secretary reported that during the past three months 15 letters had been received from widows of medical men soliciting grants and relief; they had to be refused in every case, owing to the fact that their late husbands had not been members of the society. The annual election of the secretary took place and Mr. Edward J. Blackett was appointed to the post.

BRITISH ELECTRO-THERAPEUTIC SOCIETY.—A provincial meeting of this society will be held at Leicester in the library of the Young Men's Christian Association building on Wednesday, Thursday, and Friday, July 26th, 27th, and 28th, at 10 30 A.M. on each day. The programme, which will be found in full in our advertisement columns, includes a discussion on the Present Position of the Treatment of Carcinoma and Sarcoma by Electrical Methods, which will be opened by Dr. H. Lewis Jones; a paper on Neurasthenia by the President, Dr. Donald Baynes, a paper, illustrated with lantern slides, on the X Rays in the Diagnosis of Pulmonary Disease, by Dr. A Stanley Green; and a paper on Stereoscopic Radiography, illustrated with lantern slides, by Mr. A D. Reid Dr Lewis Jones will give a further report on the Milliamperemeter as a Measure of X Ray Production All medical men are invited to attend the meetings and to take part in the discussions and those wishing to read papers or to bring forward communications should address themselves to the honorary secretary, Dr E Reginald Morton, 22, Queen Anne street, Cavendish-square, London, W.

ST. BARTHOLOMEW'S HOSPITAL.—The following is the list of scholarships awarded at the above-mentioned hospital.—The Jeaffreson entrance exhibition in arts, K. C. Bomford The junior entrance scholarships in science, T. S. Lukis and G. R. Lynn (the preliminary scientific exhibition) The senior entrance scholarships in science, E P Cumberbatch and G. Graham The Shuter entrance scholarship in the subjects of the Cambridge second M B. examination, R B Seymour Sewell. *After entrance*—The junior scholarships in chemistry, physics, and histology, T L Bomford and H H. King The junior scholarships in anatomy and biology, A P Fry and R R. Smith The treasurer's prize in practical anatomy, T S Lukis; certificates of proficiency to G. R Lynn, R R Smith, A P. Fry, and A L. Weakley. The Foster prize in senior practical anatomy, T L. Bomford; certificates of proficiency to F. C. Serle, R B Price, and A L. Chandler. The Harvey prize in practical physiology (in memory of Dr. William Harvey, physician to the hospital, the discoverer of the circulation of the blood), A. E. Gow; certificate of proficiency to A. J. S. Fuller The senior scholarships in anatomy, physiology, and chemistry, E M. Woodman. The Wix prize, W. B Grandage. The Hichens prize, F. W. W. Griffin. The Bentley prize for reports of cases in the surgical wards, P L Guiseppi, *prox. accessit*, C A. Stidstone. The Sir George Burrows prize in pathology, J. G. Gibb The Skynner prize in regional and morbid anatomy, including their reference to scarlet fever and rheumatic fever, J G Gibb. The Matthew Duncan prizes, G. C. E. Simpson (medal and first prize) and P. L. Guiseppi and E. H. Shaw (equal, second prize) The Kirkes scholarship and gold medal in clinical medicine, J G. Watkins and J. K. Willis (equal) The Willett medal for operative surgery, H. W. Wilson. The Walsham prize for surgical pathology, E. H Shaw. The Brackenbury scholarship in surgery, H W. Wilson. The Brackenbury scholarship in medicine, C W Hutt. The Lawrence scholarships and gold medal in medicine, founded by the children of the late Sir William Lawrence, surgeon to the Hospital, and father of the late treasurer of the hospital, E. H. Shaw.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Withdrawal of the Lunacy Bill

THE Government has withdrawn the Lunacy Bill It was "blocked" by Sir JOHN BATTY TUKE, Dr HUTCHINSON, and Sir WALTER FOSTER

The Medical Act (1886) Amendment Bill

This Bill, which was explained in THE LANCET of July 15th, was read a third time in the House of Commons on Tuesday and was sent to the House of Lords

HOUSE OF COMMONS.

FRIDAY, JULY 14TH

The Royal Army Medical Corps (Volunteers)

Sir WALTER FOSTER asked the Secretary of State for War whether, in view of the fact that the Army Council had refused honours in connexion with the South African war to the Royal Army Medical Corps (Volunteers), and that war honours had been granted to numerous volunteer corps which sent contingents to the war, he would state what was the average strength of the contingents sent, and whether, in view of the fact that the eight divisions of Royal Army Medical Corps (Volunteers) in various parts of the country contributed to medical units during the war some 650 officers and men, amounting to two fifths of their strength, the Army Council would reconsider its decision —Mr ARNOLD FORSTER replied It is not the custom to award honours to any but corps of cavalry and infantry, as it is accepted as a fact that all the other branches of the army have contributed in some measure to every honour which is recorded on colour or accoutrement Accordingly, no honours for South Africa were awarded to artillery, engineer, army service, or medical corps, regular or auxiliary.

MONDAY, JULY 17TH

Fees payable to Public Vaccinators

Mr. RUNCIMAN asked the President of the Local Government Board whether he proposed to issue an order giving effect to the recommendations of the departmental committee which sat to consider the fees payable to public vaccinators, and if so, when the order was to be issued —Mr GERALD BALFOUR replied The Local Government Board has not at present arrived at a decision upon the recommendations of the committee Effect could only be partially given to them by means of an order

Guardians and Midwifery Orders

Sir WALTER FOSTER asked the President of the Local Government Board whether he was aware that in some cases difficulty had arisen from poor women being unable to obtain assistance in their confinements in consequence of unregistered midwives having been warned not to attend such cases and no others being available and whether, in these circumstances, he would issue an order pointing out to the boards of guardians the duty of the relieving officers to grant midwifery orders to women destitute of the means of procuring medical attendance —Mr GERALD BALFOUR answered No case of the kind referred to has been brought to my notice If the honourable Member is aware of any such cases and will furnish me with particulars of them I will cause inquiry to be made and will consider what action should be taken

The Medical and Dental Examination of Volunteers

Sir HOWARD VINCENT asked the Secretary of State for War whether having regard to the amount of time that would be required for the medical and dental examination of the volunteer force for active service demanded by his recent circular, and to the paucity of medical officers and the calls upon their professional time, he would authorise a fee of 5s to be paid for such examination or the equivalent honorarium for the examination of a recruit for the Army by a civil practitioner, and further, whether the volunteers themselves would be reimbursed their expenses in travelling to and from the medical and dental centre —Mr ARNOLD FORSTER said There is no reason to suppose that the services will appreciably add to the expenditure of volunteer corps and it is not proposed to grant any special allowance The matter, however, is receiving consideration

TUESDAY, JULY 18TH

The Army and Navy Vaccine Institute.

Mr WEIR asked the Secretary of State for War what quantity of glycerinated calf lymph was produced annually in the Army Vaccine Institute, the number of calves operated on, and whether they were sold for human food or utilised in the military kitchens —Mr ARNOLD FORSTER answered The annual average amount of glycerinated calf lymph produced at the Army and Navy Vaccine Institute is sufficient to vaccinate 125
of calves operated on is 30
examinations are made in
public. They are not utilised in military kitchens

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication*

ANDERSON, J WILLIAM, M B, has been appointed Medical Officer to the Helston (Cornwall) Dispensary

BELL, W BLAIR, M D, B S Lond, M R C S Eng, has been appointed Assistant Gynæcological Surgeon to the Royal Infirmary, Liverpool

BULLEID, EDGAR G, M D, has been appointed Clinical Assistant to the Chelsea Hospital for Women

COOMBS, CAREY, M D, B S Lond, has been appointed Honorary Physician to Out patients, Royal Hospital for Sick Children and Women, Bristol

DANIEL PETER L, F R C S Eng L R C P Lond, has been appointed Assistant Surgeon to Charing Cross Hospital

EASON, H L, M D, M S Lond has been appointed Assistant Ophthalmic Surgeon to Guy's Hospital

FOX, JOHN ALFRED, L R C P Lond, L R C P & S Edin, L F P S Glasg, L S A Lond, has been appointed *pro tem.* Medical Officer for the Marazion District of the Penzance Union

HALL, OCTAVIUS, L R C P & S Edin, L F P S Glasg, D P H R C P S Irel, has been appointed Medical Officer of Health of Devonport

MAYNARD, F P, Major, I M S, has been appointed to act as Ophthalmic Surgeon and Professor of Ophthalmic Surgery in the Medical

MUDD, F B has been appointed House Surgeon

QUIRLEY, J E ST GEORGE, L R C P Irel L S A has been appointed Medical Officer, Obenemasi G M, Ashantee West Africa

RUTHERFORD, has been appointed Medical Officer to Ray Department, St Johns Hospital f

SAULTER, W W, M D, C M, has been appointed Clinical Assistant to the Chelsea Hospital for Women

YOUNG, ROBERT ARTHUR, M D, F R C P Lond, has been appointed Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH ROYAL UNITED HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing.

BIRKENHEAD BOROUGH HOSPITAL.—Senior House Surgeon.

BIRMINGHAM, GRAVELLY HILL, ASTON UNION WORKHOUSE AND COTTAGE HOMES.—Resident Assistant Medical Officer. Salary £120 per annum, with apartments, rations, and washing.

BRITISH HOSPITAL, Buenos Aires.—House Surgeon, unmarried, for three years' contract. Salary £200, £250, and £300, with board, apartments, &c.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

GROCERS' COMPANY.—Two Scholarships for Original Research in Sanitary Science. Value £300 a year.

HARTSHILL, STOKE-UPON TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with apartments, board, and washing.

HASTINGS, ST. LEONARDS AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon for six months. Honorarium 10 guineas, with residence board, and washing.

KENSINGTON WORKHOUSE AND INFIRMARY, Marloes road, W.—Second Assistant Resident Medical Officer. Salary £80 per annum, with apartments, board, and washing.

KENT AND CANTERBURY HOSPITAL.—Honorary Physician.

LANCASHIRE COUNTY ASYLUM, Winwick, Warrington.—Assistant Medical Officer unmarried. Salary £150 per annum, rising to £350, with apartments, board, attendance, and washing.

LANCASTER, ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

LEEDS, UNIVERSITY OF, FACULTY OF MEDICINE.—Demonstrator of Bacteriology. Salary £150 per annum.

LEICESTER INFIRMARY.—Two Assistant House Surgeons for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

LISCARD, WALLASEY DISPENSARY AND VICTORIA CENTRAL HOSPITAL.—House Surgeon, unmarried. Salary £100, with apartments, board, and service.

MACCLESFIELD, CHESHIRE COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £140, rising to £160, with apartments, board, and washing.

MANCHESTER, VICTORIA UNIVERSITY.—Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum.

METROPOLITAN ASYLUMS BOARD FEVER AND SMALL POX HOSPITALS.—Assistant Medical Officers, unmarried. Salary £180 per annum, rising to £240, with board, lodging, and washing.

MIDDLESEX HOSPITAL, W.—Emden Research Scholarship for Cancer Investigation, tenable for one year. Value £100.

NORTH EASTERN HOSPITAL FOR CHILDREN, Hackney road, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board and residence.

RAMSGATE GENERAL HOSPITAL AND THE RAMSGATE AND ST. LAWRENCE DISPENSARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, and attendance.

ROXBURGH DISTRICT ASYLUM, Melrose, N B.—Assistant Medical Officer. Salary £140 per annum, with board, rooms, &c.

SHEFFIELD, CHILDREN'S HOSPITAL (OUT-PATIENT DEPARTMENT).—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION.—Senior Resident Medical Officer, unmarried. Salary £200 per annum, with board and lodging.

WESTON SUPER MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

YORKSHIRE, WEST RIDING COUNTY COUNCIL.—Assistant to County Medical Officer. Salary £250 per annum, rising to £400.

Births, Marriages, and Deaths.

BIRTHS.

BINGHAM.—On July 15th, at Blackwell, Alfreton, Derbyshire, the wife of Frank M Bingham, M R.C.S., L.R.C P., of a daughter.

BOWDEN.—On July 18th, at Bay View, Bincleaves road, Weymouth, the wife of Fleet-Surgeon Walter Bowden, R N, D.S O., of a daughter.

LENDRUM.—On July 18th, at Manchester street, Werneth, Oldham, the wife of John B Lendrum, M D, of a son.

WICKHAM.—On July 9th, at Chernocke House, Fleet, Hants, the wife of Gilbert H. Wickham, M.B., of a son.

MARRIAGE.

SHAW—WYATT.—On July 12th, at St Mary's Porchester, by the brother of the bride, Arthur Hemans Plows Shaw, M.R C S. Eng, L.R.C P. Lond., to Mabel Agnes, second daughter of the late Francis W. Wyatt and of Mrs. Wyatt, Porchester, Hants

DEATHS.

GABE.—On July 16th, at Westwood, Ashby de la Zouche, Leicestershire, Grace Winifred, the dearly beloved wife of John Rees Gabe, M D, M R.C S Eng, of 16, Mecklenburgh square, London, W C.

ROPER.—At Keys House, Napton, Rugby, on the 18th inst, Henry Roper, B A Cambs, M.B, B.C, aged 37, youngest son of the late F. C S Roper of Palgrave House, Eastbourne. Funeral Friday, 11 A.M, at Napton.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

IMPERTINENT ADVERTISEMENT.

Mr. J. Samuda of Samuda and Co. is an enterprising person who has taken up the fashion of the "follow up" advertisement. The modern advertiser knows well the advantages of "push" and "hustle" and is quite cognisant of that weakness of human nature which makes so many persons unable to resist a proposition which is perpetually placed before them. More than this, if the proposition is worded so that it appears to be a purely personal matter it is still more attractive. We have now before us one of Mr. Samuda's letters, a copy of which has been sent to many medical men and which commences thus —

> "SIR,—
>
> "*Re My Personal and Confidential Proposition.*
>
> "As I cannot trace any reply from you to my letter of June 6th, it occurs to me that you may not have thoroughly understood my proposition."

Mr. Samuda then goes on to say that his directors have determined to make a special offer to medical practitioners distributed throughout the British Isles and the offer is this. Mr. Samuda will supply a medical practitioner with whatever quantity of Avoca cigars No. 6 at 30s. per 100 instead of 40s. All that Mr. Samuda asks in return is that "those gentlemen who accept my offer will, as opportunity arises, recommend the cigars to their friends, provided, of course, that they give positive and absolute satisfaction." But as a further inducement Mr. Samuda proceeds "I have decided to present free with the first 100 you purchase at the reduced A.D. price a real amber solid gold mounted cigar tube in Russian leather case. This, of course, is a personal gift from myself." Now we know nothing whatever of the Avoca cigars which may be good or bad. If they are the former, medical men or any other class would be glad to recommend them without being bribed to do so. If they are the latter, it is a most impertinent proposition for Mr. Samuda to offer bribes in the hope that someone will be weak enough to accept them for doing dirty work. We note a PS. to Mr. Samuda's letter as follows: "All 'Avoca' goods are sent post paid and any not approved after a thorough trial can be returned at my expense." We must confess that we cannot understand what there can be left of a cigar to return after a thorough trial.

SINGULAR DEATH OF A BOY FROM A BLOW.

Major W. B. Arundel, coroner of Pontefract, held an inquest recently at Ackworth upon the body of Arthur Wilson, aged 16 years, a stonemason's apprentice, who met with his death in singular circumstances. The evidence of the boy's friends showed that the deceased and others met a boy named Herbert Gardham, aged 12 years, who had been fishing and who had a rod in his hand. Wilson and Gardham began to quarrel and after Wilson had struck Gardham several times with his fist Gardham retaliated and struck Wilson across the region of the stomach with the fishing rod. Wilson stood for a second with his hand upon his stomach, then dropped to the ground, and after gasping twice died instantaneously. Mr. R. H. Rigby, who was called immediately, said that he tried artificial respiration for an hour but without avail. He made a post-mortem examination of the body and found all the organs healthy and quite normal. There were no external marks beyond a bruise upon the right shin of about the size of a sixpence. None of the abdominal organs were in the least diseased. Witness was of opinion that death was due to syncope consequent upon the blow. He did not think it was due to excitement. A heavy blow such as might have been given from the fishing rod produced would probably cause a reflex action from the nerves of the stomach to the nerves of the heart which would cease beating at once and death would be instantaneous. This would especially be the case if the blow were unexpected and the stomach was full of food as was the case. The deceased in the quarrel might have been expecting a blow from the rod but he could not have been expecting it where he got it or the abdominal walls would have become rigid and probably there would have been no evil result. The jury returned a verdict that death was due to syncope consequent upon the blow given by Gardham who, by misadventure and against his will, had caused the death of Wilson. It has long been known that a blow on the abdomen can cause sudden death and yet no gross lesion may be found on opening the abdomen. In such cases as this the fatal result is evidently occasioned by a reflex nervous chain, the blow on the abdomen occasioning reflexly a cessation of the heart beat. The danger of blows upon the abdomen is fully recognised by the pugilistic prohibition of blows "below the belt," but a very simple experiment will serve to demonstrate clearly the point. If the abdomen of a frog be flicked smartly, as by the handle of a scalpel, the heart will be seen to cease its beats suddenly and to resume them after a pause dependent chiefly on the severity of the blow. It can readily be shown that the efferent channel of this reflex arc is the vagus nerve which carries the inhibitory impulses. A similar nervous nexus exists in higher animals between the afferent nerves of the abdominal walls and viscera and the cardio-inhibitory centre in the medulla oblongata.

"ELOCUTIONARY ACROBATISM."

WE publish the following extraordinary letter because it well illustrates the condition of mental muddle and bewilderment into which many mystical minded people fall when thinking over the achievements of science unaided by a scintilla of scientific knowledge or training.

Montgomerys Hotel, 227, Second st,
San Francisco, Cal., June 29th, 1905.

The London LANCET.

Some time since I read of Commission on Cancer and Prince of Wales Decree therefrom. The following described cure of leprosy, puerperal and typhoid fevers, should efface Cancer and all germ diseases. 1st, What is Electricity? Holy Bible says "His voice is on the waters" Armstrongs Hydro Electric Machine shows escaping steam and water particles are positive, the boiler being negative. Vapor Vesicles ascending in the air explode and collapse into water particles which freeze into ice morsels, abounding above and between the vapor clouds. Holy Bible says "He maketh Darkness His pavilion round about Him dark waters and thick clouds of the skies. .. . He casteth forth His ice like morsels. He sendeth out His Word and Melteth them." The Lightning Flash melting the ice morsels is The Word of God or the Lord Jesus Christ or Angel of Life The Earth is the abode of the dead and is negative. This is Melchizedec or The Angel of death.

The Jews had been carried captive into Babylon until Cyrus turned their captivity. Antiochus warred on them, and Tiberus' beast nature was roused by conspiracy of The Patricians. The Jews feared Tiberius would destroy their city and nation. Thus it was a mistaken idea of Patriotism caused the San Hedrin to buy and Judas to sell Jesus Christ. There is no danger of Nebuchadnezzar, Antiochus, or Tiberius Cæsar carry our pulpit, parliament, and Court Captive, that they should have professing Christiandom disciples of Judas Iscariot in buying and selling Christ, and in changing the Magnetic pole to explode and Conflagrate the Globe.

Gospel Luke v. 12, 13, Matthew viii. 14, 15, Christ cured leprosy and fever by touch. In chronicle Clipping 24th ult. attached, Mrs Williams nearly two months sick of puerperal and typhoid fevers cured by Thunderbolt entering her room. In touching Christ induced a negative charge into the leper and fever sick which destroyed the germs as did the Thunder Bolt to Mrs. Williams 2nd Kings v., Naaman's leprosy cured by ℞ from Christ through Holy Prophet.

The Valley of Jordan is considerably below Sea Level the air is denser and richer in oxygen. The River falls greatly in its tortuous course. The friction must greatly negatively electrify, and the magnetic Oxygen or Ozone must by churning saturate water and mud. This gives therapeutic force to Jordan which Abana and pharpar lack As in Luke v. 12, 13, Matthew viii. 14, 15, and Mrs. Williams quoted the curative agent of Naaman is Negative Electricity. By the context Naamans case had advanced to ulceration which the ozonized water and mud cured. Sterilized mud is more congenial soil for bacilli than the animal body.

Revelations xxii. 2, 3. The Tree of Life leaves of which are for healing of the nations may be Paw Paw to efface all germ diseases from man and beast by digesting the Germs or microbes.

Thus may leprosy, plague, tuberculosis, cancer, and all germ diseases be eradicated until The Law of Life Testimony and Gospel be learned and obeyed by Clergy, people and rulers, rather than wicked Elocutionary acrobatism Revelations xvi. 13.

Very respectfully,
MICHAEL CAHILL

NOTE.—Radium seems to be a negative storage battery through which the positive vapor or magnetic oxygen induces a weak current not powerful enough to cure

HEALTHY COSTUME FOR GIRLS.

To the Editors of THE LANCET.

SIRS,—I have a daughter between 14 and 15 years of age and do not want her to wear corsets. I should be obliged if any of your readers would tell me where I could get information as to the best (healthiest) way of clothing her.

I am, Sirs, yours faithfully,
B A.

July 17th, 1905.

THE LATEST QUACKERY.

South Africa, if we may judge from the advertisements which appear in the local newspapers, is an even happier hunting ground for quacks than are these islands The latest dodge is a nostrum called "Sacco" which is "run" by Stevens and Co, whose headquarters are in St George's street, Cape Town. "Though it has been in existence scarcely a year," to quote the circular, there is nothing particularly new about it. We learn that "about seven years ago an Englishman travelling in a remote part of South Africa became cognisant of some remarkable cures effected by a native in cases of consumption and kindred diseases which affect more particularly the pulmonary organs. The successful treatment by what appeared primitive means so impressed the Englishman (who is now one of the proprietors of Sacco) that he was constrained to test its curative powers" Then follow the usual statements about the wonderful efficacy of "Sacco" and remarks about the conscientious beliefs of the proprietors We have heard all this before Sometimes the drug has been discovered in North America among the Red Indians, sometimes, as in the case of "Corazza," in Mexico and we fully expect one day to see some enterprising quack bring out a remedy, the receipt for which has been discovered on the top of Ararat, having been left behind by Noah. The usual testimonials are attached and also, as usual, we cannot find any of the London addresses given in the Post Office Directory. According to the conscientious proprietors "*This* preparation has never been known to fail to *Perfectly cure* any case of *Consumption, Hæmorrhage, or Asthma*. .. .. We claim that if a person has half of his or her lungs left we can effect a permanent cure, providing, of course, the patient does his or her share by keeping to our directions" We have no hesitation in saying that the statements in this circular are wicked perversions of the truth and Stevens and Co have had the impertinence to send it to sundry medical men, asking them to give the nostrum a trial. It is cruel and immoral to raise false hopes in the minds of sufferers from tuberculosis. Stevens and Co, however, are no worse than hundred of other quacks and we are still waiting patiently for the law to be amended, so that such heartless swindles may be put an end to

A NURSE INSPECTOR OF SCHOOLS.

To the Editors of THE LANCET.

SIRS,—I call your attention to the following paragraph from to-day's *Western Mail* (Cardiff) —

> "A few months ago the executive of the Barry District Nursing Association placed at the disposal of the local education authority for a period the services of a nurse to visit periodically the schools of the town and examine the children for minor injuries and ailments It is understood that a recommendation will now be made to the education authority to appoint a schools nurse at a salary of £80 a year, such appointment to be made being and under the control (like the members of the teaching staff) of the education authority and not the Nursing Association."

This is putting the nurse in the position of a qualified medical practitioner and placing a premium on unqualified practice If a nurse will "visit . . and examine for minor injuries and ailments" she will also be emboldened to prescribe and dispense, &c. So many are the irregular rivals to medicine that many medical men must be sorry that they went to the trouble and expense of getting qualified.

I am, Sirs, yours faithfully,
July 17th, 1905. L R C S, &c.

⁂ The Barry District Nursing Association does not instruct the nurse to treat the cases; presumably she is only to inspect the children with the view of preventing the existence of communicable diseases or physical defects being overlooked The master or mistress of the school ought to be able to do some of this work. The pathological condition being detected, the medical man ought to be summoned All this work could be done by medical men if schools were carefully grouped for inspection and the medical inspectors were properly paid —ED L

A GUIDE TO LEICESTER.

WE have received a copy of a Guide to Leicester and Neighbourhood, by Mr G. Clarke Nuttall, B.Sc, and published by Mr Edward Sharlow, St. Martin's, Leicester. A copy of this guide is to be presented to every member of the British Medical Association on registering his name Leicester has a most interesting history and there are apparently a good many of its old buildings left The guide will certainly be useful to visitors.

FLANNELETTE.

"A SURGEON" writes —

> Some months back you published a correspondence and added your own observations on the various processes for reducing or preventing the inflammability of flannelette and thus the number of severe burns arising from this cause. I send herewith a packet of a powder called "Boram", it is claimed that flannelette dipped in a solution of this is rendered fire resisting I send also two pieces of a cheap flannelette costing 2¾d. a yard, one piece as bought, the other treated with "Boram" You will see that the latter will not burn at all it merely chars It is in this respect better than flannel itself, and, in fact, perfect
>
> As to cost, "Boram" is sold retail in packets costing 1s 6d. each The contents are to be dissolved in a gallon of water and the solution thus made will render fire resisting 12 square yards of canvas or 20 square yards of muslin, therefore it costs somewhere about 1*d* a yard to fireproof flannelette Unfortunately, the salt being soluble, it is necessary to redip the garment each time it is washed, it is, however, a great gain that, though not without trouble and expense, flannelette can be rendered quite incombustible

We have examined a specimen of "Boram" and our analysis easily revealed its composition We are able to confirm what "A Surgeon says in regard to a solution of this salt rendering flannelette practically non inflammable The salt is prepared by the Fire Resisting Corporation, Limited, of Townmead road, Fulham, London, S W.

THE UNQUALIFIED ASSISTANT.

To the Editors of THE LANCET.

SIRS,—Supposing a case like the following occurred, what is your opinion? Also that of your readers? A practitioner employs a lady housekeeper who also acts as assistant, surgery attendant, and collector She receives patients and prescribes for them, and is preferred in many cases to the medical man Under the new Midwives Act she has obtained a certificate as a midwife In the urgery is exhibited a large card as follows:—"Midwifery attended y Miss ——, L.A., &c. Fee 10/6."

I am, Sirs, yours faithfully,
A STRUGGLING PRACTITIONER.

*** We have frequently pointed out that, to some extent, the Midwives Act legitimises for women the post of unqualified assistants, a post which the General Medical Council has decided to suppress in respect of men. As a certificated midwife Miss ——'s duties are defined (more or less) by law and if she goes outside them she can be reported to the Midwives Board. As a surgery attendant and dispenser she can assist her employer as long as she acts under his supervision, but if, being unqualified, she visits patients independently and prescribes for them her employer can be punished by the General Medical Council—ED. L.

A. B. C.—We have seen that paragraph about the hospital dance, the kind hearted constable, and the titled surgeon many times before. Its details are apt to vary, but the constable is always kind hearted and the surgeon is always titled, the adjectives in some way or other being supposed to add to the horror of the yarn. That "the facts are too circumstantial to be disputed" is the most silly assertion of all. Nothing less circumstantial has ever gone the rounds of a credulous press.

Anon.—Will our anonymous correspondent who sent us a bill from Morecambe communicate with us (giving his name). We cannot comment upon the matter unless we know what actually happened. The bill only states what is going to happen.

Inquirens.—We have no information to give on the matter of the study of medical electricity apart from study for the medical profession.

R. P.—The man is only the usual mendacious quack.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

Presidential Address

ON

MEDICAL EDUCATION—PAST, PRESENT, AND FUTURE.

Delivered at the Seventy-third Annual Meeting of the British Medical Association on July 25th, 1905,

BY GEORGE COOPER FRANKLIN, F.R.C.S. ENG.,
HONORARY SURGEON TO THE LEICESTER INFIRMARY.

[AFTER the usual words of welcome to the Association, and having expressed his thanks for the honour which had been accorded to him in his election as President, Mr. Franklin proceeded to give a short *résumé* of the history of Leicester. After mentioning the names of Goulston, the founder of the Goulstonian lectures; Cheselden, the famous surgeon to St. Thomas's Hospital; Halford, for 24 years President of the Royal College of Physicians of London; Benjamin Ward Richardson; and Tom Paget, of the Leicester Infirmary, the first provincial surgeon to obtain a seat on the Council of the Royal College of Surgeons of England, all of whom were Leicestershire men, the President passed to the main subject of his address. He said:—

I now propose, ladies and gentlemen, having referred to local matters in connexion with the medical profession of, I hope, some interest, to venture on some remarks with regard to the existing regulations by the State of the education of those who desire to become members of our profession. In doing so, in considering how the education is regulated to-day, I must, as a necessary preliminary, consider to some extent the regulations of the past, and then we can ask if the improvements of to-day are as great as they should be, if the regulations are producing the best possible results; if, in fact, the average student, when he or she leaves the medical school or hospital legally qualified, is as well equipped as possible for the responsibilities of the future. That this is a tremendous problem we recognise at once, when we consider for one moment what it means to a country, or rather to a series of countless communities, to have among them thoroughly well educated representatives of the medical profession. As it is absolutely impossible to suppose that a civilised community could exist without such representatives it follows, surely, that those communities in which are found the most highly educated members of the medical profession have an enormous advantage as compared with others. It seems to me that the importance of the education of the medical man or woman of to-day is greater than ever it was and the responsibilities of those who are engaged in teaching are also greater than ever.

THE APOTHECARIES ACT.

Now, as far back as 1722 there was an Act which empowered the Apothecaries' Company to visit the shops of all apothecaries practising in London and to destroy such drugs as they found unfit for use. In 1748 great additional powers were given to the Company by an Act authorising them to appoint a board of ten examiners, without whose licence no persons should be allowed to dispense medicines in London or within a circuit of seven miles round it. The celebrated Apothecaries Act of 1815 appears to have been the first Act to legalise medical practice and penalise unqualified practice and this was really the start in this country of any regulations recognised by the State with regard to the education of apothecaries, the then general practitioners. The General Medical Council did not come into existence until 1858, the date of the first Medical Act. Between 1815 and 1858 there seems to have been a sort of "hiatus," but two important events helped towards the first Medical Act—viz., the establishment of THE LANCET in 1823 and the founding of our Association in 1832 by Sir Charles Hastings of Worcester under the name of "The Provincial Medical and Surgical Association."

It will be interesting to refer to two or three clauses of the Act of 1815 before we proceed further—to Clause III. for example. The Masters and Wardens were empowered to enter shops of apothecaries and to examine drugs:—

> They shall or may search, survey, prove, and determine, if the edicines, simple, or compound, wares, drugs, &c., and any thing or things whatsoever therein contained and belonging to the art or mystery of apothecaries aforesaid, be wholesome, meet, and fit for the fare, health, and ease of His Majesty's subjects.

Again, in Clause VII. we read:—

> Whereas much mischief and inconvenience has arisen, from great numbers of persons in many parts of England and Wales exercising the functions of an apothecary, who are wholly ignorant and utterly incompetent to the exercise of such functions whereby the health and lives of the community are greatly endangered, and it is become necessary that provision should be made for remedying such evils, be it, therefore, further enacted that the said Master, Wardens, and Society of the Art and Mystery of Apothecaries of the City of London shall be empowered for ever to superintend the provisions of this Act and carry the several regulations and provisions thereof in relation to the several persons practising the art or mystery or profession of an apothecary throughout England and Wales into full execution.

Then follow clauses to appoint examiners and to appoint a chairman, all to hold office for one year, but to be eligible for re-election. Clause XIV., "To prevent any person or persons from practising as an apothecary without being properly qualified to practise as such," enacts that they should be examined by the court of examiners and receive certificates, provided always that no person shall be admitted to such examination until he shall have attained the full age of 21 years, and in Clause XV. it is enacted that such person must have served a five years' apprenticeship. Clause XX. provides for a penalty for practising without a certificate.

THE MEDICAL ACT OF 1858.

Coming now to the first Medical Act of 1858 we find it established a Council to be styled "The General Council of Medical Education and Registration of the United Kingdom, with branch councils for England, Scotland, and Ireland, consisting of representatives from the universities and corporations." The chief achievements of the Council have been the establishment of a preliminary examination and inducing the corporations to leave it to the national educational bodies, the visitations of examinations, and the publication of the Medical Register and of the Pharmacopœia. It has had some faults of course; the chief has been its want of sympathy with the great body of the profession, especially with regard to the representation of the profession in the Council.

A great defect of the Act of 1858 was that it permitted the separate registration of purely medical and purely surgical diplomas and therefore diplomas which did not guarantee an adequate acquaintance with all the subjects of professional examination were used by their holders to cover the whole ground of medical, surgical, and obstetric practice. In May, 1869, Mr. (afterwards Sir) John Simon said that persons practising on half qualifications were to be counted by thousands in the United Kingdom. Between 1858 and 188 nearly 20 Bills were introduced to remedy these main defects. In 1870 Lord Ripon's Bill was brought in to establish a simple code of regulations common to all the examining boards of the United Kingdom, sufficient and uniform tests of qualification as a condition of entry upon the Medical Register, a more or less consolidated examining authority, and more effectual provisions to restrain quacks. The principle was accepted by the Council but the Bill was wrecked by the opposition of the British Medical Association on the ground that no provision was made for the representation of the profession in the Council. The Government Bill of 1878 was a great improvement; among other things, it required that all persons desiring to be placed on the Medical Register should have both a medical and surgical qualification and it contained provisions for amending the 40th Clause—"Suppression of Unqualified Quacks"—and for the admission of women; o examination. It also provided for the examination of, and registration of, dentists and midwives and amended the law relating to certificates of lunacy.

THE MEDICAL ACT OF 1886.

The celebrated Act of 1886 removed two conspicuous blots in the organisation of our profession. It made it necessary for every medical man to be qualified completely—*that is*, in the three main branches of practice—medicine, surgery, and obstetrics—before he can be placed on the Medical Register, and it has conferred representation on the great body of the profession.

MEDICAL EDUCATION IN LONDON 40 YEARS AGO.

In the "sixties" London students were gradually waking up to the fact that, although the College and Hall gave them the two qualifications which entitled them to be placed on the Medical Register, the diplomas did not give them the legal right to assume the title of "Doctor." Many men—hard-working and possibly ambitious—when coming up from the county to the hospital board of the University of London for the first time. Anyway, the University of London gave a degree, and why should they not go in for it? To show you how ill adapted the teaching was in those days in the London medical schools for those students who desired to graduate in London I will quote from a letter addressed in December, 1879, to the Chancellor of the University by a distinguished graduate, my old friend and teacher, Dr. J. S. Bristowe.

> Only a small minority of the students entering the medical profession in England offer themselves as candidates at the matriculation examination. Nearly 50 per cent. fail; of those 50 per cent. fail at the preliminary scientific examination. Of those who have passed this examination 35 per cent. fail at the first M.B. and of those who finally become candidates for the M.B. degree 19 per cent. are rejected. The collective result is that not 10 per cent. of the young men who enter at the lowest series of the examinations emerge successful at the last and that at least 72 per cent. are rejected at the matriculation and preliminary scientific examinations.

Dr. Bristowe observes that at that time there were 534 men living who held a medical degree in the University of London out of a total of nearly 25,000 practitioners holding British qualifications. The practical result of this is well known; scores of men left the London hospitals before their time was completed to obtain degrees in Scotland, Ireland, or elsewhere. In short, the system of education 40 years ago in the London medical schools, as far as there was any system, was designed to enable men to qualify at the College and Hall or at the two Colleges as soon as possible—this could then be done in four years or just under—and not to encourage work for the University of London degree.

Of course, I am well aware that some very good work was done, more especially in medicine and surgery; but in obstetrics and gynæcology the practice and instruction were alike insufficient. It must be remembered when referring to the medical education of 40 years ago that those were the days of the linseed-meal poultice (in the surgical wards), antiseptics were just beginning to be used, the clinical thermometer appeared on the scene, together with the laryngoscope and the ophthalmoscope. The clinical teaching was then, I suppose, nothing like so systematic as it is now, but some of the lecturing was most excellent. I might refer to the lecturing of the late Sir John Simon, then Mr. Simon, on pathology at my old school of St. Thomas's. He used to lecture to, perhaps, hardly a score of students. It would have been of immense advantage if he could have lectured to every medical student in London; a man of his learning and intellect was, in a way, almost wasted down in the old Surrey Gardens, but there was no attempt at concentration of professional studies in those days. If I were asked, In what respect do you think the medical education of 40 years ago was most deficient? I should without hesitation say it was deficient in three particulars: (1) preliminary examinations; (2) obstetric medicine; and (3) the administration of anæsthetics; and if I were asked to-day the same question I should give precisely the same answer.

MEDICAL EDUCATION OF TO-DAY.

Now I have referred to the regulations of the past, I will briefly consider those of to-day and note the improvements that have been effected. I may then, perhaps, venture to forecast what further advances may be made not only in the interest of the medical student but also to the advantage of the whole community. By the regulations of the General Medical Council no person can be registered as a medical or dental student who has not attained the age of 16 years; some, a great many, think the age ought to be 17 years. I am one of those. Further, no person can be allowed to register unless he or she shall have previously passed a recognised preliminary examination in the subjects of general education. The period of professional study between the date of registration as a medical student and the date of the final examination for any diploma which entitles its holder to be registered under the Medical Act must be a period of *bonâ fide* study during not less than five years. Now this period of five years is a minimum time and it obtains whether the curriculum be passed in England, Scotland, or Ireland, and whether the student is going in for a university degree or a college diploma; as a rule, of course the university man takes a longer time. The universities and medical corporations seem now to work on the same lines though differing in the severity of examinational tests—lines laid down by the General Medical Council. For instance, the curriculum and examination of the Conjoint Board have now been brought much more into line with those of the University of London and other universities than was formerly the case. This, of course, is so much to the good.

Now I will suppose a young friend (to start well, we will hope he has passed the matriculation examination of the University of London) has registered at the age of 16 or 17 years. What has he to do by the time he is 21 or 22 years of age? He has a journey of three stages: (1) elementary science, including chemistry, physics, elementary biology, and practical pharmacy; (2) anatomy and physiology; and (3) medicine, surgery, and obstetrics. If he passes his first two examinations all right he has two and a half to three years left for the study of the more purely medical subjects and it is perfectly appalling to think of the lectures and other work which the student must attend during the last period of two and a half or three years. I am persuaded that the laity has not the remotest idea of the number of subjects that the medical student has to tackle. Speaking generally, he has to attend lectures in medicine six months, surgery six months, obstetrics three months, pathology, bacteriology, pharmacology, and therapeutics three months, forensic medicine, public health, together with systematic practical instruction in medicine, obstetrics, and surgery; operations on the dead body, attendance on the practice of a recognised hospital for two winter and two summer sessions, post-mortem demonstrations for 12 months and clinical lectures on medicine and surgery. He must also attend clinical instructions in ophthalmic surgery, insanity, and diseases of women, and must act as clinical clerk and surgical dresser for not less than six months each and attend 20 obstetric cases. Instruction in vaccination and in the administration of anæsthetics and attendance at a fever hospital are also required.

I have said that the laity has no idea of the amount or of the variety of subjects to be studied. Another point that cannot be grasped or understood is why when our young friend has passed his three examinations, has done all his work, and has obtained his diploma from the Conjoint Board, he has not earned the legal title of "Doctor." I do not propose to discuss this question now. I only remark in passing that it seems to me that the British public will decide it—in fact, are deciding it now, for as a matter of convenience, if for nothing else, the title of "Doctor" is given to the medical practitioner nowadays much more generally than formerly, in fact, almost universally. Even in our journal I notice that the "Conjoint man" is styled "Doctor." I think, then, it will be obvious to everyone that great improvements have been made within the last two decades particularly, and that the general standard of medical education has risen considerably notwithstanding the fact that too much of the average student's time is spent on biological and chemical studies, and that too little time is given to ward work. I have ventured to point out what I consider to have been the main deficiencies of the past. I mentioned that in three particulars I thought the medical education was deficient—namely, (1) preliminary examination; (2) obstetric medicine; and (3) the administration of anæsthetics; and now, notwithstanding the great general advance all along the line, there is a pressing necessity for much improvement in these three respects.

1. *Preliminary education.*—At the root of all progress lies the improvement in the general and professional culture of those about to enter the medical profession. Can anyone deny that some of the preliminary examinations of to-day are too easy? They are not sufficiently stringent to secure a proper standard of culture. I do not think that any student should be put on the Medical Register unless he has passed the matriculation examination of the University of London, or one of equal stringency. In the good time coming, when all medical students will be undergraduates of a university, and will be obliged to take a degree in arts, this question of preliminary examinations will be solved; until then we must do the best we can. I think the advantages of a good classical education early, to a man entering our profession, cannot be over-rated. Nothing will, or can, make up for it; there would not be so many candidates deficient in ordinary spelling and composition if there had been a good classical education. To my mind there is nothing really superior to the old-fashioned Latin and Greek training but it seems hopeless to insist nowadays upon the retention of Greek. I think it is 25 or 30 years ago since, in the matriculation examination of the University of London, students were allowed to take up German instead of Greek. I venture to think that, as far as medical students are concerned, that was a retrograde step. I do not envy the student sitting down to learn

his anatomy who has not learnt even a little Latin and Greek; his Gray's Anatomy, perchance, in front of him, his Latin dictionary on one side, and his Greek lexicon on the other. The student, too, must not begin to specialise too soon, he wants a liberal education, an education for its own sake. This goes when the technical education begins—that is, when he leaves school or college to learn to be a "doctor." I was most interested to observe that about two months ago the Lord Chancellor, as warden of the Guild of Undergraduates of the University of Birmingham, when delivering his address, said he thought there was a grievous omission in that University—there was no chair of Greek—and he hoped they would clamour for such a chair and that Birmingham munificence would be effectual in procuring it.

2. *Obstetric medicine.*—With regard to the education in obstetric medicine and surgery, I would insist that its importance is not appreciated as it should be. This is a subject of which a very practical view should be taken. It is supposed that out of ten newly qualified medical men who leave hospital some seven or eight of them go into what is called, for want of a better name, "general practice"—become general practitioners. Now, what is the basis of general practice? Anyway, in a practitioner's early years it is obstetrics. The young practitioner who has his living to get is not long in finding this out and in finding out, too, that when he has to rely on his own knowledge and judgment he does not feel himself so well equipped as he thought he was. The remedy for this is obvious—much more practical work before leaving hospital. It is trifling with the subject for it to be deemed sufficient that a man should have attended not less than 20 obstetric cases in order to be signed up.

3. *Anæsthetics.*—I have a word to say about anæsthetics. The administration of an anæsthetic is a duty which may devolve on any practitioner at any moment almost. He should therefore feel himself quite capable to undertake this duty. I believe that good instruction is given at the medical schools in this subject at the present day. Anyway, there is a vast improvement in this respect as compared with what obtained in my student days. Then, indeed, unless a man was sufficiently fortunate to obtain his house surgeoncy he had no opportunity for any practical experience with regard to the administration of anæsthetics. For many years I have had unusual opportunities of observing the capacities of men, freshly qualified, who have come from various schools all over the country to fill the resident appointment at our infirmary and whose duties have included the administration of anæsthetics. There can be no doubt that in recent years men have been better up to this particular work. All the same I think that at the average hospital medical school the importance of a thoroughly good education in this department is not sufficiently insisted upon.

MEDICAL EDUCATION IN THE FUTURE.

Now that I have had my grumble at what I have ventured to call "deficiencies" in the medical education, both of the past and of the present day, I feel myself at liberty to say that though the average young medical practitioner in this country is a better educated man than he ever was, there is still room for improvement. But difficulties arise at once. If there be more subjects to be studied or subjects to be more thoroughly studied, how in the world is the time to be found? I have alluded to the tremendous amount of work the student has to get through, particularly in his last three years; is it right that it should be so, and is it possible that he can leave out some of the prescribed work and give more time to other subjects so as to learn them more thoroughly? The histology of to-day, together with physiology, so elaborated that its study must take up a much larger proportion of time than formerly, are subjects necessary enough, but are they not being pushed too far? The future practitioner is not expected to be a professor of physiology any more than every student can be a scientific physiologist. Just so with regard to bacteriology, which has become so much of a science that it might well in itself constitute a study for a lifetime. It must be studied, but its teaching, like that of histology and physiology, should be adapted more precisely to the actual needs of the practical physician or surgeon of to-morrow.

Perhaps the most startling fact of to-day in connexion with medical education is the apparently inevitable development of the specialist. The Medical Act of 1886, to which I have already alluded, provided that no one should be admitted to the Medical Register who has not been examined and is not qualified in medicine, surgery, and obstetrics. The so-called general practitioner is one who practises these three, many add pharmacy, and thus practise as apothecaries. Whatever line a man takes eventually he must have qualified as a general practitioner. One might be inclined to ask whether the general practitioner will, as such, continue to exist when one contemplates for a moment the subdivisions of work that are undertaken by the specialist. Thus we have not only special men for the eye, ear, spine, skin, throat, and so on, but for almost every organ in the body. How has this condition of things arisen? I think I can assign two main reasons: (1) the severe competition which awaits a well-qualified man when he is about to start in practice; and (2), though perhaps this ought to come first, the demand of the public. The public do not believe in universalism as applied to the practice of medicine but they pin their faith to some specialist who has taken up some particular ailment or organ of the body. An old fellow student of mine, now holding a high position as a consulting physician in London, told me that a lady of distinction brought her child for him to see because she had been given to understand that he was a specialist for children between the ages of seven and eight years and her child was just seven and a half years old! Seriously speaking, this condition of things has to be recognised: it has come to stay, whether for the greatest good of the greatest number is more than I can say; I can only hope so.

Of course, we all agree that some special departments in our profession are absolutely necessary; take, for example, that of public health. Now the supreme authority in sanitary matters in this country is the Local Government Board, with its chief medical officer and its medical and other inspectors; and all urban and rural sanitary authorities are required to appoint medical officers of health having registered qualifications in medicine and surgery. The duties of a medical officer of health are tremendous (in an average town such as Leicester, for example) and require a most extensive and liberal education. The man who would aspire to so honourable a post must specialise early in his professional life. Think what he has to do. The Local Government Board directs that he shall inform himself respecting all influences affecting, or threatening to affect, injuriously the public health within the district. He shall be prepared to advise the sanitary authority, worthy aldermen and common councillors alike, on all matters affecting the health of the district. He shall direct and superintend the work of the sanitary inspectors. He has to be able to give a decided opinion as to whether some articles (meat, game, fish, and the like) when exposed for sale are fit or unfit for food. He has to write numberless reports on all sorts of subjects and to report every quarter to the Local Government Board, and oftener if there should be any epidemic. He has to prepare an annual report up to the end of each December containing tabular statements without end with regard to sickness and death-rate. In matters not especially provided for the medical officer of health must obey the instructions of the Local Government Board and the lawful orders or directions of the sanitary authority. Since I have been in practice it has become necessary to notify to the sanitary authority all cases of contagious diseases and the medical officer of health is expected to be able to decide immediately in doubtful cases of infective disease; for example, he must decide at once whether a case be one of modified small-pox or of severe chicken-pox. He has, in fact, to constitute himself a "final court of appeal." It is now suggested that his duties should be added to in connexion with the supervision of midwives under the new Act.

Now surely the education of a man who is to carry out these duties thoroughly well must have been very special—in fact, directed towards public health *ab initio*. Although it has nothing to do with my argument, I may here express my firm opinion that our Association will be doing a great work if it will use its influence to favour the principle or policy of "fixity of tenure" as applied to competent and well-educated medical officers of health. The present conditions of service are not satisfactory, to say the least.

As another instance of special work in our profession, work requiring special aptitude and education, I would refer to the insane. In these large asylums which unfortunately seem to have sprung up, and are springing up, all over the country and which are harbours of refuge for the most afflicted and the most to be pitied of our fellow creatures are to be found men of our calling who have devoted, men who are devoting, their lives to the improvement of the treatment and surroundings of those unfortunate people intrusted to their care. Within the last half century the treatment of the insane has been revolutionised—improved in every possible way. This has been due to the specialists—to men who have *made* the care and treatment of those of unsound mind their special study. And so I might go on; it really seems as if the medical profession is soon to consist of a series of professions and that those who enter it, if they intend to make a decent living, will have, quite early in professional life, to decide each one on his particular line. Of course this is not really so.

The two illustrations I have given of specialism in public health and lunacy are illustrations of legimate specialism, but that there is a type of specialism existing with which we are not all in accord no one will deny. A healthy specialism has been defined as "a practice of a special branch of treatment, a study of a special domain of knowledge of a natural and gradual growth in the varied experience of a practitioner." Something like this has always existed in medicine, greatly to its advantage, and is very different from the specialism of what I have heard described as the mushroom growth variety, where chicanery and humbug reign triumphant. There can be no doubt that honest specialism has advanced the science and art of both medicine and surgery, particularly during the last 30 or 40 years. But, as has often been observed in many other lines of human activity, all subdivision of labour, while advancing the best interests and development of the people at large, has great disadvantages for those engaged in the work. *This is seen* constantly in many industrial pursuits, when mechanics or workmen become almost like machines, devoting their constant toil and energy to one small section or subdivision of work, and are relatively useless *in regard* to other portions of the same industry. There is, *then*, the danger that this modern development *of specialism* may tend to produce a narrower type of medical men who, like the mechanics, will *only know their own* department and work, and be unable to understand properly the relations of special portions of the field of medicine to others or to the system at large. Whether this may be so or not, the main point to keep in view, while always admitting that specialism is with us, is "*whether or not the practical result is good?*"—first, as *affecting the* public, and, secondly, as affecting the profession. To both of these questions I unhesitatingly say Yes, and from my experience of practice and patients I make bold to declare that the public might derive more help and benefit than they do if they knew what to have and what to avoid in the way of specialism. Now here is the opportunity and a well-defined duty for the well-educated practitioner. He will see to it that his patient shall not become (if he can help it) a patroniser of the false specialist (legally qualified or not). After all, it seems to be a matter of trust, and just in proportion as you have young men coming thoroughly well trained from the medical schools so you will have a corresponding amount of confidence on the part of the public. The way in which specialism is affecting the profession has already been alluded to and I only say again that the chief danger seems to be the development of a narrower type of medical man. I think before leaving this subject of specialism that I may take the opportunity to express my regret that nothing seems to be able to be done to check the advertising specialist—enterprising advertisers who claim to cure diseases without seeing the patients (claim to do, in fact, what is impossible of accomplishment) and so use the daily press and religious and magazine publications for fraudulent purposes, for that is what it amounts to. In America, I think, there are greater sinners in this respect than there are here but in England they are bad enough and it is a matter of painful surprise that proprietors of high-class newspapers and magazines can allow such rubbish to be shot into their advertising columns. There must have been great defects in education somewhere or such a condition of things would never be tolerated.

I have intimated that, to the best of my judgment, the average young practitioner of to-day is a better man than he was 30 or 40 years ago, but I want him to be better still, to be more thoroughly equipped, and would not the public gain immensely if this were so? The university education is the first pressing necessity. I have alluded to the good time coming when all medical *students* shall be undergraduates of a university *and shall* have to take a degree in arts. I hope it is not a dream; but that another generation will see its accomplishment. It is undoubtedly the fact that medical men of a former *generation* whose sons are now entering the profession send them, if they can possibly affor it, to one or other of the universities; again, when th student's time is over in the *five or six* years, wh should it not be obligatory that he should hold som responsible resident appointment *for* six or twelv months before going *into* practice? As a matter fact, it is more often so than not, but now that ther are more opportunities for resident appointments it woul be a wise regulation that every man should have th experience. I have known many men who have regretted i after years that they had no such opportunity. I ma perhaps offer one more suggestion to the newly qualifie practitioner, and that is that he should at once join th British Medical Association. The British Medical Association, as I have *mentioned*, was founded at Worcester in 183 At its *first* annual meeting, a year later, it numbered 14 members. Its success has been very marked. I think tha there are some 20,000 members, but the success will not b complete until every registered practitioner becomes a membe The British Medical Association exists for the promotio of medical and the allied sciences, it also exists for th maintenance of the honour and the interests of the profession. I will not labour this point now, I may hav another opportunity, but I would earnestly invite ever newly qualified practitioner to join our Association as a matter of course.

I suppose all of us when students indulged more or less i "hero worship." I am sure I did and I have already mentioned the name of one of my heroes. I mean the late Si John Simon. He was appointed lecturer on pathology a St. Thomas's Hospital as far back as 1847. He was then 31 years old and on that occasion he gave an inaugural address and I propose to conclude my remarks to-night, which I sincerely wish had been more worthy of this distinguished audience, by quoting some of his final sentences. Mr. Simon —*this genius*, surgeon, pathologist, and poet-philosopher—was addressing a very learned audience, *not only* students. He said:—

> But finally, ... nor can I refrain from reminding you, ... to run is no beaten track of traditional ki . . . . . . — we have jointly to study is yet but in its first dawn and immaturity and the terms of my commission here have imposed on me as an especial duty to institute researches for the purpose of unveiling the latent processes by which disease is established and the curative processes by which it is removed. To coöperate with me in these researches and go far beyond me in achieving their great results I earnestly invite and exhort you. I bid you enter on a field of science where industry must have its reward in an unparalleled harvest of discovery—a field now first beginning to bear fruit, with promise of unmeasured fertility. If you have energies in you, beyond the mere care for sustenance, how can you better or more nobly bestow them than in original investigations which have nature for their field and the alleviation of human ill for their final purpose? It is in no transient access of enthusiasm, but in the deepest conviction of my judgment, that I affirm the supreme dignity of such pursuits; that I affirm them not only to be in themselves the loftiest occupation of the human mind, but to include the largest and most enduring rewards. To be the successful interpreter of nature, to discover her hidden laws of operation, or by your personal exertions to augment the permanent resources and utilities of medicine—this implies as its result to be remembered so long as man and outward nature coexist; *to be remembered as the ornaments and benefactors of your species.*

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—Of 19 candidates who entered for the intermediate examination held in July 12 passed: J. W. Agnew, H. G. Dale, James Dick, jun., W. P. Hayworth, I. M. Heilbron, R. F. Innes, S. Judd Lewis, A. J. C. Lickorish, F. L. Okell, R. P. Page, H. J. B. Rawlins, B.Sc. Lond., and D. R. Wood. In the final examination for the Associateship (A.I.C.), of five examined in the branch of Mineral Chemistry three passed: J. B. Hoblyn, Assoc.R.C.Sc. Lond., G. W. James, B.A. Oxon., and H. H. Kingdon, B.A. Oxon.; of six in Organic Chemistry four passed: A. W. Bain, B.A., B.Sc. Lond., T. W. Cheke, J. Stuart Hills, and D. F. Twiss, M.Sc. Birm.; and of nine who entered in the branch of the Analysis of Food and Drugs and of Water, including an examination in Therapeutics, Pharmacology, and Microscopy, four passed: R. W. Blair, Assoc.R.C.Sc., I., P. H. Carpenter, J. A. Goodson, and S. Summerson, B.Sc. Lond. One candidate passed an examination for the Fellowship (F.I.C.): E. F. Harrison, B.Sc. Lond.

Address in Medicine

ON

MEDICINE, PRESENT AND PROSPECTIVE.

Delivered at the Seventy-third Annual Meeting of the British Medical Association on July 26th, 1905,

BY HENRY MAUDSLEY, M.D. LOND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN, WEST LONDON HOSPITAL.

[IN the introduction to his Address in Medicine Dr. Maudsley disclaimed any intention of reciting the story of its victories. His desire was to indicate in a general way how with advances day after day its horizon widens and its expectations of service to mankind increase. He also inveighed strongly against the present practice of inventing and multiplying portentous words of Greek or Latin or mixed root to describe simple things and then proceeded as follows:—]

Looking out on the present state and prospect of medicine it is obvious that its future work will be mainly to prevent and to stop the beginnings of disease—to take good order that it shall not come and if it do come to prevent functional disorder from lapsing into fixed disease, which must be given over either to the surgeon's knife or to the shears of Atropos; for to despise the little things of functional disorder is to fall by little and little into organic disease. Now preventive medicine has two plain ends, the one of which is being pursued with signal success, the other not duly studied. The first, by all fit measures and precautions to defend the body from those attacks that come from without, whether in gross form or as invisible microbes floating to and fro on earth to assault and to hurt it; the second, to obviate the predispositions to disease which lie within the body by giving it inward strength to resist its subtle, ever-present, ever-active enemies—in fact, to teach it to die at last from old age as every medical man ought theoretically himself to do.

The success of preventive war against disease is manifest in the decrease of such diseases as plague, typhus and typhoid fevers, small-pox, malaria, and hydrophobia. Here medical art, having learnt definitely what it has to fight against, employs definite measures of defence and attack for a definite end. So it has relinquished the fearful bleedings, purgings, vomitings, and druggings once in fashion. Think for a moment on what happened when medicine blindly attacked symptoms at first sight, on the sort of treatment, for example, which a poor wretch suffering from scabies underwent before the insect of that disease was discovered. What mischievous measures again were employed to provoke the pouring out of "laudable pus" where no pus should be! That the practice of warring against symptoms, which are effects and signals, perhaps useful outlets, of the disease by trying to suppress them instead of striking at the cause and letting the symptoms alone is now obsolete, would be too much to say; it is long since the violent lowering of high febrile temperature by frequent doses of antipyrin was the fashion; and still, I fear, large use is sometimes made of opium, chloral, and their like to quench the fire of acute mania, notwithstanding that, smothered for the moment, its flame blazes more fiercely afterwards to the prolongation of the disease and peril of the patient's life. A lesson of human history which the history of medicine signally confirms is that error does not become truth because it is repeated thousands of times by many thousand persons. Might not the lesson haply be applied to the valuation of some current medical theories? I suspect that if a competent thinker, constituting himself a sort of *advocatus diaboli*, were to write a book entitled "Medical Doubts," setting forth reasons why some accepted truths may not after all be true, he would do a real service to medical science.

For the adoption of requisite measures to ward off disease and nip it in the bud the medical man does not get full and fair opportunities. Summoned to the bedside of one actually ill, the disease having got its hold, he sees the sick man for the first time when, being sick, he is not his true self. Ignorant, therefore, of the patient's constitution and habits, of his temper of body and mind, all which count for much in the prescription of sound rules and directions, he is not so qualified to counsel wisely as if, called in beforehand to advise against sickness, he possessed the necessary elements of comparison between the sound and unsound man to instruct treatment. For it is a diseased person, not an abstract disease or absurdly called morbid entity, which he has to handle; and in most persons, I imagine, there is present the weak organ or tissue which is liable to fail in function under strain, and in the end begins to die first. To treat the same disease in the same way in all persons is to do much like the tailor who supplied all his customers with clothes made to the same measure, without taking their particular measures. If medical men give physic but seldom take it—as the old gibe is—may not that be because, knowing something of their own constitutions, and of the causes and beginnings of disease, they adopt timely measures of precaution and a system of treatment sorting with their habits and temper of body and mind?

The second aim of preventive treatment—thrown into the background now by the eager quest of the microbe—is to obviate the predispositions or tendencies to disease which lie within the organism. For such predisposition exists, whether or not, disliking the word, we like to speak instead of a constitutional soil suiting the microbe; facts not being changed by being named differently, though men are very apt to think so. Not to speak of the want of a full and exact study of radically different types of constitution and of their respective qualities and disease tendencies, of which little note has been taken since the abandonment of the old doctrine of temperaments, there is a strange want of any study of the effects of the interbreeding of parental disease tendencies upon the constitution of the offspring. Might not some good come from systematic inquiries into the production and elimination of constitutional disease tendencies and disease immunities by the marriage unions of different tendencies and immunities? When a person has a disease unlike that which either parent had he may still owe it to them, variations occurring in morbid heredity just as they do physiologically. The case, of course, is not one of the breeding together of actual diseases—no metaphysical conjunction of morbid entities—but of two physical organisms tending to go wrong in their respective ways. What is the morbid outcome of the union of a phthisical and an insane diathesis? As bad as it well can be, I should say. Or of a diabetic and a phthisical constitution? What is the constitutional disposition, if any, most likely in breeding to cancel a tendency to cancer? For, eager as the search is for a cancerous microbe, one may doubt whether it has yet been tracked to its late suspected lair in the nucleus of the cell. Having regard to the local invasions and distributions of cancer, its provocation by local irritation, its more than accidental heredity, and its quiet settlement in the system without feverish tumult, for all the world as if it felt itself no alien intruder but constitutionally at home there, it seems probable that its unruly proliferation of cells, however provoked, betrays the awakening to activity of the silent memories of ancestral germinal growth. How best mate the person having a native tendency to insanity so as to cancel it in the progeny, or, better still, convert it into a good evolutional variation? For that is what happens sometimes, one child of a neuropathic family dying in a lunatic asylum, while another rises to eminence as poet, painter, orator—great man of some kind. Why and under what conditions is the epilepsy of one generation transformed into the insanity of the next generation? How is it that diabetes and insanity go along together in some families or alternate in them through generations? When medical science can answer these and like questions it may then dictate some wise eugenic rules. Meanwhile in the uncertainties of things we do well to trust—and we can have no surer trust—that *vis medicatrix naturæ* by which, health being the normal and stable, disease the accidental and passing condition, it comes to pass with the race through generations, as with the individual in his brief life, that the organic strain constantly is to rectify deviations and to bring disorder back to order, so keeping mankind in continuance, if not progress, of being for its appointed time on earth.

[Here Dr. Maudsley discussed whether in the marriage union of disease tendencies a new disease is ever born and concluded that there is a limit to the capacity of a definitely constructed organism to go wrong and suggested that the organism may now have exhausted its morbid capabilities. He continued:]

In the work of fortifying the body to resist inroads of disease the most simple means are the best and, as Hippocrates said, it is in the use of simple means that great physicians especially differ from others. Pure air, clean and proper food, regular and adapted exercise—these sum up the measures prescribed as proper to give inward strength and to keep it in sound and supple activity. But they are not quite all, for they leave out mind; and as a sound body is the condition of a sound mind so the wholesome exercise of a calm and well-disciplined mind, ready to meet all changes and chances with composure, ministers mightily to health of body. Corroding passions and unruly affections, such as anger, envy, jealousy, revenge, lusts, and fears of every kind, are a hurt to body as well as mind, so that rules of wise mental culture and exercise are an essential part of the regimen of health. When one contrasts the simplicity of the salutary rules with the usual stolid violation of them it might seem that men were in love with disease, such pains do they take to provoke and nourish it. Knowing well that fresh air is a good thing they go on in practice to shut it out lest a stray draught come their way; so little care do they take to eat only what is needful that they habitually eat twice as much as is good for them; so reckless are they of what they drink that they persistently abuse alcohol to obtain temporarily an ideal relish which the insipidity of their real life denies them; so perfunctory is the routine of daily exercise they take in dull mechanical pacings that they rehearse their lives by rote, never bringing into full use half the possible movements of their bodies and less than half the faculties of their minds; so little mindful are they of the need of rest to overworked function that, so long as sexual power lasts, they spend it recklessly in the gratification of lust, thinking no harm provided the exercise be connubial.

That the body is a complex reflex mechanism is now a familiar notion, strange and ignored as it was when Descartes first conceived it more than 300 years ago, expressly setting it forth then in a series of distinct propositions which, as Huxley said, constitute the foundation and essence of modern physiology of the nervous system. The conception, untimely born, fell into utter neglect. Even now, after so many years, but little has been learnt scientifically of the manifold bodily reflexes or sympathies—motor, sensory, secretory, and nutritional—although everybody might make the needed observations on his own person, and a full and an exact knowledge could not fail to be put to excellent use in practice? How is it that a patch of psoriasis on one leg, although itself left untouched, is cured by curative applications to a similar patch on the other leg? Certain it is that a clear conception of the reflex mechanism of the organism as a whole and an exact knowledge of the reflexes or sympathies of its parts will yield much profitable use, not only through systematic and skilful employment of kneadings, rubbings, pressings, and such-like manipulations and appliances whereby an infirm organ may be more benefited sometimes than by many, or perhaps any, drugs, but also by regulated exercises purposely adapted to bring into wholesome action all the muscles of the body, whereby every muscle may be made to contract and every minute vital channel kept open and so disease prevented or stopped at its outset. Moreover, as the "life of relation" (using Bichat's term) from the cradle onwards is the organic education, mental and physical, of a reflex mechanism whereby that which is consciously and laboriously learnt is expressed easily and automatically—such gradual instruction being organic construction—a constant aim ought to be to fashion it well, as well to know how it works best and to keep it in the best working order.

[Dr. Maudsley then pointed out that after all the application of the principle of the reflex mechanism of the organism was not in the end due to Descartes but to those who, coming after him, worked laboriously to establish and confirm it, and that science owes a service of thanksgiving to its obscure worthies like the Church holds to its uncanonised saints on All Saints' day. He continued:—]

The present posture of medicine in relation to tuberculosis shows a wise recognition of the necessity of fortifying the body inwardly to resist its outward enemies. The noxious bacillus has been caught, it is true, but its capture has not been followed by the discovery either of a protective serum to immunise the body or of an antitoxic serum to extirpate the bacillus in it. Bacilli, like the poor, we shall doubtless always have with us; nor can we ever hope to keep them out of the body, as surgeons once fondly hoped to do with their carbolic sprays, and food sterilisers would fain do now, notwithstanding that they may thereby destroy one half the nutritive value of the food; that a recent observer has isolated more than 100 different kinds of bacilli in the juices and deposits of the human mouth; and that another observer has found in the healthy intestine a large number of organisms intermediate in character between the typical colon bacillus and the typhoid bacillus. Here, I think, one may justly regret a want of sobriety in some medical statements on the popular platform in consequence of which the public have jumped to the conclusion that because the bacillus has been discovered phthisis is curable, the old notion of its heredity erroneous, the objection to phthisical marriages obsolete, and the right thing to do forthwith to dot the land freely with sanatoriums, and so gain an immense addition to the life-capital of the nation. But is phthisis so very curable in these special hospitals, nowise endued with any special grace, I imagine, by reason of their being called sanatoriums? Adequate statistics are not yet available, but thus far the modest outcome of experience seems to be that many patients who are sent in the early stage of the disease recover, if they are kept long enough; that most of those in a more advanced stage improve while there, frequently relapsing afterwards; and that those who are badly diseased ought not to be sent at all. Is that, after all, to say much more than might be said of sensible treatment before the erection of sanatoriums? In the end, means must be found to mend the fit constitutional soil and breeding ground of the bacillus, if it is to perish of inanition for want of its human food. The startling proposal that subsidary institutions should be set up, in which those who are not cured may be taken care of for the rest of their lives, can hardly please the burdened ratepayer who may think that a nation's chief aim ought to be to have healthy bodies and minds which can endure all changes and extremities, not such as must be protected artificially from them.

Can we, again, eliminate the predisposing influence of heredity? Actual tubercle may not be inherited—nobody thinking clearly on what he thought ever thought that it was—but the poor constitutional soil inviting and suiting the bacillus still passes from parent to child; and we do not get rid of the essential fact by changing the name. Do we, indeed, in the end get such a valuable addition to the life-capital of the nation? It is easy enough, noting that some 60,000 consumptives die annually in England and Wales—I do not vouch for the figures—fancifully to rate the value of each life at an arbitrary figure and then by multiplication to make an appalling computation of the loss to the community; but is the loss so real? Might not the ultimate cost to the commonwealth be greater were these persons to go on living and breeding in it? An addition to the nation's life-capital is all very well, but the quality of the capital counts for a good deal and it will not count for much if it is not realisable. What does the realisation amount to in practice? The patient who comes out of the sanatorium recovered or improved must usually go back to his former work and surroundings; he cannot adapt the world to the weakness of his nature and its ideal needs, but, like other mortals, must adapt himself to the rude world and perforce do much as they do. That is what he quite naturally does; returns to his work and his old ways, perhaps gets married if he is not married, and begets children who can hardly have the confidence of a good descent. Meanwhile, when he relapses, he sows bacilli broadcast, thus multiplying such life-capital to fulfil its ordained function in the universe, that apparently being to make away with weak mortality.

However, I shall not pursue a tender subject further. Human life is so precious nowadays in all its states—phthisical, insane, criminal, inebriate, and the like—that it is the pious duty of the social organism not, as the healthy bodily organism tries to do, to extinguish or extirpate a morbid element but to absorb it into its system, growing sympathy being the vital principle of social growth. The medical man, at all events, can plead his duty to his individual patient; he is not sponsor for the nation's future; that he leaves to those whose business it is. Still, a sceptical-minded person—he would be called a cynic—looking to the ultimate issue of such morbid absorptions, might be tempted to exclaim with the prophet: "My people love to have it so, and what will ye do in the end thereof?"

To the clear and distinct conception of the body as a complex reflex mechanism, in which there is mutual intelligence of parts with entire community of interests, we have to add the conception of it as a vital laboratory of the most complex chemical substances and processes in the world engaged in the most condensed and subtile activities. We easily think of it as a wondrous community of innumerable cells that have undergone various differentiations to form different tissues; but when scientific imagination goes deeper into the minute subtilties of matter a living cell seems but a gross thing. Concentrated within its little body are subtile and intense forces, continuously and quietly working, which, if let loose in large explosive display, might suffice to blow up the chemist and his whole laboratory. No wonder, then, at the increasing knowledge of the important part which chemical activities play in vital processes. Considering closely how many different chemical actions enter into each of the various bodily functions of the body—assimilation, respiration, secretion, excretion, generation, sensation—all going on harmoniously to maintain a unity of being, yet each liable to incalculable disorders, the eternal wonder is that it holds together so long and so well as it does. In the performance of these functions not the whole organism only but every cell of it generates poisons which would be fatal if they were not got rid of. The breath of man is fatal to man; his excretory products would poison him if he did not get away from them or them away from him; the fatigue of an organ or tissue is not due to the using up of its energy and matter only but also to the toxic products of waste which pass into the blood stream and are hurtful when they are not perchance of economic use to other organs or tissues. The proteid molecule of food suffers decomposition into a dozen intermediate products before its elements are built into living tissue and at every stage of the series there is the possibility of a pernicious vitiation. The various kinds of enzymes or ferments which work in the processes of metabolism, each producing its particular chemical change, are liable to their several toxic mischances. In its normal state the intestinal canal contains numerous poisons and possibilities of poison—mucus, albuminoids, alkaloids, and aromatic and biliary substances. Thinking on the many risks of self-poisoning and on the exact chemical agency requisite to counteract each of them scientifically, it seems a lawful conclusion that more medical good will be done for the most part by simple and general measures to keep the body in health and strength than, according to Voltaire's witty sneer, by pouring drugs of which we know little into a body of which we know less.

Besides the subtile chemical poisons of physiological disorder medicine has now to tackle the special toxins generated by the various hostile microbes and the far-reaching damage which they do—so far-reaching sometimes as to have no end but the end of the life which they end. The syphilitic virus, whether microbic or not, is the proclaimed cause of tabes dorsalis and general paralysis. Years after his specific infection and its supposed cure a man is attacked by the flashing pains portending a tabetic degeneration of his spinal cord or exhibits the inflated feelings and ideas preceding the cerebral devastation of general paralysis, both diseases going down thenceforth to their fatal endings. Strange to think that one kind of microbe can be the latent cause of the variety of symptoms, having regard to their differences in different cases, the elective affinities for particular organs, and the long suspensions of activity during which it must lie dormant, only to awaken from time to time to virulent fury. One may suppose, perhaps, that the specific virus, however generated, affects injuriously the stability of the nerve molecule, an effect nowise apparent while the person is strong and well but manifestly destructive when vitality of nerve element is weakened by abuse of function or other cause. For it is with elements of tissue as with individuals: to be weak is to be miserable.

In the discoveries of microbic toxins and their antitoxins and of the immunising virtues of antitoxin serums there is a discernible promise of scientific therapeutics when chemical agents will be used, not empirically, but with scientific precision for a definite end: an optimistic outlook all the more legitimate, seeing how the chemist in his laboratory, by substitution of atoms in molecules, now creates new substances which, so far as we know, never existed before in nature and some of which have proved to be of good medical service. Thus creating, our hope is that he will on the whole turn out to be a benevolent creator by inventing more beneficent than maleficent compounds for human use; range himself, in fact, on the side of the good genius of the universe. The rapid progress of chemical research, steadily sapping the barrier between organic and inorganic nature, has now reached the very confines of life, even forecasting an ultimate analysis of those subtile physico-chemical processes whose mysterious unity of action in the organic molecule we provisionally call vital force. Six years ago a president of the Chemical Section of the British Association for the Advancement of Science affirmed that, no matter how successful the reduction of vital to physico-chemical activities, a residuum would always evade such explanation and require an intelligent directive agency; but the latest researches of stereochemistry into enantiomorphous substances seem to show that the enantiomorphous agency working in the dead universe may dispense with the need of the metaphysical assumption. However that be, certain it is that day after day, with every step forward in physics and chemistry, proofs accumulate that all vital processes rest at bottom on physical and chemical processes of the same kind—although raised to a higher power—as those which take place out of the living body.

Deep as the chemist penetrates into the subtilties of matter, there is a yet deeper order of inquiry into the mysteries of the infinitely little and its most potent forces. The discovery of radial rays, perpetually thrown off in radio-active dissociation with an energy greater than that liberated in the most violent chemical decompositions, has taught us that the atom is not a simple thing but a spot of positive electrification within which swarms of negative electrons whirl their mazy rounds with inconceivable rapidity. Thus the chemical elements, each with its individual properties, originate in differences of the number of electrons and the figures which these take as they whirl, and all matter is resolved at last into moving electric charges—material nature simplified into electricity and ether. Remote as such speculation appears to be from the realities of life the story of applied science furnishes many striking instances of theories so abstract as to seem of no conceivable use, which have, nevertheless, in ways quite unexpected, effected extraordinarily useful revolutions in practice; and it is not therefore unlikely that full and exact knowledge of radial energy and of its mode of action on the vital processes may instruct and guide to yet undreamed success the radial treatment of disease, some fruits of which have already been empirically gathered.

Here, then, thought again reaches a point where the domains of the living and the non-living are no longer separated by a chasm; where, indeed, one might think (if one did not suffer thought to be governed by words) that the domains of matter and life, even of life and spirit, meet, the material being sublimed into the vital and the vital into the spiritual. That all divisions of science shall gradually be effaced, even that which metaphysics has fixed between bodily and mental life, the partitions being received as conveniences of thought, not as sections and separations of substance, is inevitable, if all nature be one process of orderly evolution and the function of science be to find it out. The absolute barrier between mind and body set up by metaphysics has in truth been a great hindrance to the progress of positive science. That mind works upon body to alter the rate and quality of its functions and, conversely, body upon mind to affect its moods and thoughts is a truism, but a truism the full truth of which is not realised because of the habit of setting mind and body over against one another as separate and independent entities. Between material energy and consciousness there is a gulf, it is true, just as there is between one mode of perception and another, but it is not possible in biology to set up a partition between mind and body. Mind works in every function of the body; a sound body is the foundation of a sound mind; and the lunatic is lunatic to his finger ends. Moreover, they surely disclose one another, although by more subtile writing than we can yet read. It is not by the medium of words only that thoughts and feelings are expressed. They are expressed by other motions that are sufficiently distinct to be perceptible by sense—by subtile motions of look, gesture, gait, attitude, and the like; the differences of which in different persons are characteristic exponents of natural differences of thought, feeling, and action. Mind does not merely affect the body, it permeates its constitution and is delineate in the map of it. On the other hand, there is not a function of any organ of the body which does not enter into the constitution of mind; the reproductive glandular function notably revolutionises its thoughts and feelings during adolescence; the defective thyroid maims and lames it; an atom or two going astray in metabolism precipitate it from the height of joyous vigour to the depths of impotent despair. No purposive movement could ever be made but as the outward discharge of mind incorporate in fit structure; for the cleverest man in the world could not button a button, even stir a step, had he not learnt the art by repeated practice—had not, in fact, patiently organised intelligence in proportional, that is *ratio*-nal, structure which thereafter discharges itself automatically. When the intelligent act, once learnt and fixed, is done unconsciously exactly as it is done consciously, it is absurd to say that there is mind in the one act and not in the other. The organic process is simply one of doing consciously in the individual lifetime that which has been done gradually in the formation of animal and human instincts by evolutional adaptation through the ages. In both cases the result is structually consolidated reason, mind statical. The intimate and essential unity of mind and body is, of course, pathological as well as physiological. When the paralysed patient's power to speak or walk is restored by a strong impression made upon mind by a miracle-working shrine, or by the suggestion of a skilled hypnotist, there takes place a physical excitation of the suspended function of the nervous tract or area in which the belief and will to act were implicitly organised. For the seeming miracle to occur there must, naturally, be mutual sympathy and belief in its success; an interposed screen of doubt or disbelief prevents the excitation or inspiration of the requisite faith. To ascribe the result to imagination is one sort of provisional explanation. Certainly, as imagination may kill, so also it may cure. But that, after all, is to explain nothing—is to do little more than to make a faculty of a word.

What is the nature of the subtle transfer of energy between he active and the recipient mind whereby the former excites he latent belief and energy in the latter? Without subscribing to the strange stories of telepathy, of the solemn apparition of a person somewhere at the moment of his death a thousand miles away, of the unquiet ghost haunting the scenes of its bygone hopes and endeavours, one may ask whether two brains cannot be so tuned in sympathy as to transmit and to receive a subtile transfusion of mind without mediation of sense. Considering what is implied by the human brain with its countless millions of cells, its complexities of minute structure, its innumerable chemical compositions, and the condensed forces in its microscopic and ultramicroscopic elements—the whole a sort of microcosm of cosmic forces to which no conceivable compound of electric batteries is comparable; considering, again, that from an electric station waves of energy radiate through the viewless air to be caught up by a fit receiver a thousand miles distant; it is not inconceivable that the human brain may send off still more subtle waves to be accepted and interpreted by the fitly tuned receiving brain. Is it, after all, mere fancy that a mental atmosphere or effluence emanates from one person to affect another, either soothing sympathetically or irritating antipathically? Think in this relation on the extraordinary (so-called) magnetic personalities which some persons possess, and, again, on the contagious fire of emotion which spreads quickly and gathers volume in a crowd of people, inflaming them, as the case may be, either to deeds of mad fury or to corybantic displays of religious fervour.

Now, as fuller and exacter knowledge of the reflex mechanism of the body adds to our means of preventing and curing its disorders, and increasing chemical knowledge points to scientific therapeutics, so may a just conception of the subtilties of the forces at work in mental action inspire a more advised and methodical use of the resources of mind to cure diseases of body. Is it not from neglect to employ such intelligent measures that patients fall into the hands of nature-curers, Christian scientists, mesmerists, and the like faith-instilling persons and are sometimes cured when drugs have failed? And is it not to the use of such means, albeit not consciously formulated, that the popular practitioner, whose small medical knowledge is the smallest part of his skill, gains the coöperative belief of his patient and owes his fashionable success? It is all very well to say that people are ignorant, foolish, credulous. Of course they are. The world would not have gone the way it has gone were the immense majority not gladly beguiled; but if you would influence the fool, for his good you must enter by sympathetic imagination into the fool's mind and discern the motives by which it can best be moved. And it is still the fact that, as Cicero said of places in his time, every place swarms with fools. Sick persons, even when not foolish, are notably sick in mind mostly need a mental tonic to stimulate their weak vitality, such inspiration serving sometimes to animat tissues to a strength of vital resistance from which noxious bacillus retreats baffled—yes, even though greedy there and scents the fit soil it does not find fit climate. Few drugs are more helpful than hope, deadly than despair.

If the procession of nature be an orderly evol of things up to the mental organisation of man, slowly perfected through the ages and still perfec and the growth of man's understanding and p takes place through growing knowledge and ob ance of its laws—being a growth of nature through h part of it—medical science will obviously play a large in the future improvement of the race. In his desi found a science of *Eugenics* by discovery of the law good breeding in families Mr. Galton would have well-co tuted persons chosen to mate with well-constituted per looking forward to the establishment of a suitable auth to grant certificates of good health of mind and body to who propose to marry, so that eventually a superior h stock may gradually be produced. Inasmuch, howeve the inferior persons would go on breeding after their the result might be two species of human beings, a r clean contrary to the philanthropic principles of a democ age, which aspires to embrace the lowest specimen o race as a man and a brother—in heaven ultimately, a events, although not for the present on earth. The pro of human breeding, however, is far from so simple as of the lower animals, both as regards the forces conce and the nature of the desired product. Man is a very plex organic mechanism, framed to function, not like or dog in certain set ways, but in fine thoughts and feeli these being the superior essence of him; and it no follows that an otherwise perfect physical constitution along with a perfect mental constitution, or that you not breed a mind of extraordinary quality from a and lame body. The owner of racehorses, basing trust on a law of heredity, no doubt does wisely to a thousand guineas for a yearling colt of a distingui sire, when he would not give a thousand shillings for offspring of a poor sire, but it would hardly be wis buy the offspring of a human genius at a like proportio cost. In the human organism, with its varieties of chan moods and passions, there are delicate influences affec gravely the processes of reproduction which invalidate clusions drawn from observation of the comparatively sin organic machines which animals are; for these subtile-po forces of mind assuredly constitute a medium which powerfully on the formative processes of the delicate ge not otherwise than as on a lower and coarser level slight perimental changes in the physical medium are now exp mentally shown to effect strangely the development of germs of sea-urchins, caterpillars, and the like.

Complex and uncertain as the matter is in the human c it is nevertheless certain that there are laws of mental br ing yet to be discovered and it is no more unlawful to inq scientifically into the nature of vice and sin than into nature and action of poisons. Hatred is as natural as hu and stands in no less need of scientific explanation. That m qualities are not dependent upon physical constitution, h no physical connexion whatever, is an opinion wh although fostered in the supposed interests of morality really a hindrance to the growth of practical morality. one thing is certain it is that all wrong-doing, whether er vice, or sin, is avenged on earth; not always, it is true, the individual wrongdoer, but somehow, somewhere, on oth bound together with him vitally in the social system. Co men be taught to know and knowingly feel this simple tr they might be more heedful of their thoughts, feelings, actions than they are apt to be while they ignore the st law of vicarious punishment on earth and relegate recompense of their doings to another life. Even for own sake the evildoer might pause in his course if he thought himself that the habit of a life is the orga fashioning of a character and that a persistent system bad feeling and conduct means a steady deterioration character—means, in fact, the physiological undoing in mental organisation of the fine filaments of thought a moral feeling, the delicate nervous tracery, which have be the gain of human progress through the ages and, being t latest and finest organised, are the first lost in every form mental degeneracy.

A sobering thought, too, it might be that the mischief does not end with the individual life. From that which is evil what good can come? In the moral as in the physical world the present is the natural product of the past and the determinant of the future. Moral deterioration in the parent is pretty sure to be visited somehow upon the mental constitution of the children and the children's children, for grapes do not grow on thorns in the moral any more than in the vegetable world, and it is, I believe, the moral or affective, not the intellectual, nature—the tone of feeling infused into the forming germ—which counts most in human heredity. If that be a lesson which medical research will some day demonstrate scientifically one can heartily endorse the saying of Descartes, who was well versed in the physiology of his time and was himself a diligent dissector, that if mankind is to be perfected, the means of perfecting it must be sought in the medical sciences. For my part I cannot doubt that a positive science of human nature, as it gradually emerges into form, will make it ever more and more plain that, by operation of natural law in the process of organic evolution, sound thought, good moral feeling, and devotion to a high ideal are the solid foundation of health and wealth of mind in individuals, in families, and through families in nations; that there was, indeed, a measure of scientific truth in the saying of the Hebrew seer who, looking on the generations of old, declared that those who sow upon the furrows of unrighteousness shall reap them sevenfold.

Address in Surgery

ON

ASCENDING CURRENTS IN MUCOUS CANALS AND GLAND DUCTS, AND THEIR INFLUENCE ON INFECTION: A STUDY IN SURGICAL PATHOLOGY.

Delivered at the Seventy-third Annual Meeting of the British Medical Association on July 27th 1905.

BY CHARLES JOHN BOND, F.R C.S. ENG.,
HONORARY SURGEON, LEICESTER INFIRMARY.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—When I look through the names of the distinguished surgeons who have delivered the Address in Surgery at the annual meetings of our Association during the last 50 years, I feel very strongly that my own thanks are especially due to the Council of the Association in thus honouring me by asking me to address you on the present occasion. Among those names to which I have referred one of the most distinguished is that of Professor Syme of Edinburgh who gave the Address in Surgery at the annual meeting at Leamington in 1865. Syme concluded his survey of the progress of surgery during the previous 40 years with these words:—

> In conclusion, Mr. President and Gentlemen, I beg to express my hope that from what has been said surgery will not appear to have stood still, or pursued a retrograde course during the last 40 years, but, on the contrary, to have been improved in many important points of practice and to hold out the prospect of further advance, so that when, forty years hence, some senior member of the Association shall take a similar retrospect, he will find no lack of materials for illustrating the march of progress.

Sir, it is 40 years this year since these words were spoken; what, then, shall we say to-day in fulfilment of Syme's prophecy? We may, I think, safely affirm that next to the enormous strides which the science of surgery has made in this period (a very large share in which triumph belongs, among other honoured names, to Syme's own son-in-law, Lord Lister), that next to this advance one of the most notable of the lesser changes has been the decentralisation which has sprung up in surgical practice. London, Edinburgh, and Dublin no longer act as exclusive centres, to which converge the surgical patients from the three divisions of the United Kingdom. Excellent surgical hospitals and homes, and competent and able surgeons, are found nowadays in all provincial towns of any size, while many of th ts and advances in surgical technique and surgical methods have had their birth in the country. In my judgment this great change has been wholly beneficial. It has, I believe, been of enormous benefit to surgery itself, and there is abundant evidence in every town to show that it has been the means of conferring untold blessings on the population of our country, both rich and poor.

I venture to think that it is partly to the recognition of this principle of decentralisation by the council of our progressive British Medical Association that I must attribute your kindness in asking me, a provincial surgeon, and not even a very senior member of the Association, to address you to-day. And hence I regard the honour conferred upon me not alone as personal, but as a compliment paid to my colleagues of the Midland branch and of the town of Leicester.

I propose, in using the opportunity now afforded me, to depart somewhat from usual custom and instead of attempting a retrospect of recent surgical triumphs and of advances in surgical technique I would rather try to throw the searchlight of inquiry in the other direction and indicate some of the ways in which these very surgical triumphs may themselves throw light upon physiological and pathological problems and in this way enable surgery in some slight degree to repay something of the debt she owes to these two foundations of her existence. For when we come to consider the enormous number of what are really human physiological and pathological experiments which are performed daily for necessary and well-defined surgical objects and to save life; when we reflect on the great opportunities which the continuous observation of these operation cases affords of looking into the inner processes of bodily function, both healthy and diseased, we are bound to inquire whether we, as surgeons, have in this respect carefully observed all that we might have done and whether we have utilised to the utmost our many opportunities. Thus, to come closely to the matter of my remarks to-day:

THE LARGE INTESTINE.

Consider for a moment the very frequent—nay, the daily—establishment of fistulæ for surgical purposes. The operations of colotomy, cholecystotomy, nephrotomy, cystotomy, with the resulting fistulous openings into bowel, gall-bladder, kidney, and urinary bladder should enable us, if rightly studied, to observe something of what goes on in the hollow viscera, the biliary canals, and the urinary tract, when the fæcal stream or the biliary or urinary flow is wholly or partially diverted from its normal course. We will consider the fistulous opening in the bowel, established by the operation of colotomy, first. I have in several of these cases tried to ascertain what occurs in the bowel below the colotomy opening by means of the introduction of some insoluble, innocuous pigment, such as hollow suppositories containing a few grains of sterilised indigo or carmine, and will record the results in several cases.

CASE 1.—This was a case of cancer of the sigmoid colon with obstruction. About six inches of the bowel were removed with the growth and partial end-to-end anastomosis was performed, but owing to the patient's condition from obstruction a colotomy anus was also established. A week later, after recovery, a carmine suppository was introduced into the rectum. A white gauze plug inserted into the lower colotomy opening showed distinct carmine colouration within 24 hours and this colour continued to be noticeable for several days after the suppositories were discontinued.

CASE 2.—The second case was one of advanced cancer with almost complete obstruction high up in the rectum. Here again, after inguinal colotomy, an indigo suppository placed within the rectum was followed by the appearance of indigo at the colotomy lower opening within 24 hours. Here the indigo had passed through the malignant stricture.

CASE 3.—This case was one of inguinal colotomy for cancer of the rectum, with ulceration into the vagina. A suppository containing powdered sterilised litmus was introduced into the rectum on Nov. 28th at 8 P.M. The bowels were moved through the upper colotomy opening on Nov. 29th and 30th, and on the 30th the white gauze plug in the lower colotomy opening was stained blue; the blue colour turned red on the addition of acid, thus showing not only that the litmus had traversed the sigmoid flexure, through the stricture, from the rectum, but also demonstrating that the intestinal mucus, and the secretion of the large intestine, is alkaline in the absence of fæcal matter.

CASE 4.—This case is of peculiar interest. An operation for acute appendicitis with abscess, six months previously, had resulted in a fistulous opening into the cæcum, which discharged a very little fæces in the right iliac region when the patient assumed the upright position. While recumbent practically the whole of the fæces was passed per anum. Before closing the fistula indigo suppositories were administered twice daily on Dec. 12th, 13th, and 14th. Distinct evidence of indigo from the cæcal fistula appeared on the 15th, the bowels having been moved freely on the 13th, 14th, and 15th, and an aperient taken by the mouth on the 12th and 14th. In this case the particles of indigo traversed the whole length of the large intestine within at most three days and during the time that the natural downward passage of fæcal matter was going on and in spite of the active clearing of the bowel on two occasions by aperients.

From these cases we learn: first, that in the large intestine in cases in which the fæcal stream has been diverted by a previous colotomy there is an upward current capable of carrying foreign particles, such as powdered indigo, along the bowel and taking about 24 hours to pass from the anus through the sigmoid flexure to the colotomy opening. The shortest time recorded has been 12 hours. Secondly, that this current is not arrested by the presence of a stricture in the rectum, provided that there is, of course, some patency of channel left. Thirdly, from the case of the girl with the cæcal fistula we learn that it is not essential for this upward current that the fæcal current should be wholly diverted or absent, or that the bowel should be prevented from undergoing brisk downward peristalsis, the effect of an aperient. Fourthly, from the same case we learn that this ascending current takes about three days to pass from the anus along the whole length of the large intestine to the cæcum.

In offering any explanation as to the means by which this upward carriage of pigment particles is brought about we must remember:—1. That in the case of the indigo, at any rate, the particles are insoluble in the intestinal juices. Indigo administered by the mouth is recovered unchanged, as far as microscopic appearance goes, from the fæces, so that the material is conveyed in particulate masses, probably by a mucous steam, and not by the agency of phagocytes or wandering cells. 2. Also the current is absent in the dead bowel and is not due to capillary flow in a closed tube. If, for instance, indigo is inserted into the lower end of a sheep's colon removed after death no ascent of the powder occurs in the tube. 3. Further, even in healthy animals in the absence of any fistulous opening there is some upward flow, though slight, along the bowel. Indigo inserted into the rectum of a guinea-pig may be found when the animal is killed 48 hours later in the fæces higher up the colon. 4. Also, the current is quickened by any influence, such as the administration of an aperient, which acts by increasing peristalsis, or very possibly by increasing the secretion of mucus. This was shown in the last case.

In fact, a consideration of the facts strongly suggests the explanation that the particles of indigo, &c., are carried up the bowel by a mucous current and that while there is a central downward current of solid or semi-solid fæces, caused by peristaltic contraction, there is going on at the same time intermittently, or possibly alternating with the downward peristalsis, an upward peripheral mucous stream, covering and hugging the intestinal mucous membrane and capable of conveying minute particles only along with it. Some sort of upward intestinal current has been suspected in the large bowel and hypothetically spoken of as due to reversal of the peristaltic wave. This is an unlikely explanation from the facts mentioned above—that it is present while the downward peristalsis is going on at its normal rate, and also when the bowel is quite empty of any fæces at all. I venture to think that these facts have a not unimportant bearing on the physiology of the large intestine. By means of such an upward stream the nutritious fluids and particles which are being absorbed out of, or squeezed out of, the gradually solidifying and hardening fæces as they traverse the colon are carried gently upwards into the emptying upper reaches of the bowel and are presented to the free mucous membrane for readier absorption. They, too, have a direct bearing on therapeutics and on the administration of enemata, both nutritive and purgative.

THE FEMALE GENERATIVE TRACT.

We now pass to the consideration of the female generative canal. Here surgical operations on the Fallopian tubes have afforded opportunities for careful observation. In a considerable number of cases during the last two years in which it appeared likely that operation would become necessary on the appendages, after the preliminary douche a little coloured pigment—in most cases purified and sterilis indigo, in a few carmine—has been either placed upon, inserted just within, the os uteri at varying periods up to hours before operation. Careful microscopical examinati of the contents of the Fallopian tubes in these cases h nearly always shown the presence of indigo or carmi particles, while in several cases the pigment has been four on the peritoneal surfaces of the broad ligament, mes salpinx, and the fimbriæ of the Fallopian tubes. This show that the particles are carried from the os uteri below, rig through the uterus and the Fallopian tubes, to the peritone sac around the ovary above. In the case of these pigme particles automobility (such as the spermatozoa possess) i of course out of the question and we must fall back on ciliar action or an ascending mucous stream along the contiguou walls of the mucous canal.

In 22 cases in which careful examination was made of th contents of the Fallopian tubes and peritoneum for th presence of indigo introduced into the os uteri at periods u to within 20 hours before operation there were only four i which no pigment was found. Of these four cases one wa a case of double hydrosalpinx, in which any connexion wit the uterine cavity was difficult or obliterated. In one th indigo had been inserted only 16 hours before operation In two cases the indigo was inserted on the first day o the establishment of the menstrual flow and probably faile to enter the uterus. On the other hand, positive result were obtained in three cases of double pyosalpinx, in one case of uterine fibroid, and in two cases of tubal pregnancy in which rupture or tubal abortion had occurred. One of these is interesting from the fact that the remaining left ovary and tube had been removed two years previously. The indigo was found in the bloody mucous contents of the tube on the uterine side of the rupture and in the blood filling the conception cavity. Indigo was also found in two cases of chronic appendage disease in which the indigo was inserted on the last day of the menstrual period and in two cases of hysterectomy which are of special interest. In one the patient was 70 years old and therefore the uterus was senile. In the other the uterus was removed some months after the artificial menopause produced by oophorectomy 12 months before. These two cases clearly show that this upward mucous stream is not dependent on the functional activity of the uterus, since it occurs in the senile and post-climacteric organ as well as in the actively functional state. In two cases of large ovarian cysts pigment granules were found on the peritoneum and in the contents of the tube dilated and stretched over the cyst wall. In the case of suppurating ovarian cyst with pyosalpinx indigo was found in the pus in the tube. It was also found in three cases of chronic inflammatory disease of the appendages, probably gonorrhœal in origin. In one case of large pyosalpinx and ovarian abscess on one side and hæmosalpinx on the other operation became necessary while the temperature was 104° and 28 hours before operation pus began to escape from the uterus. Indigo was found in the bloody contents of the left tube but not in the pus in the right tube or in that of the ovarian abscess. No doubt the particles were washed away from the uterine opening of the right tube by the flow of matter from the opening.

I desire also to draw attention to the presence of the indigo within the pus cells in one of the two cases of pyosalpinx. The granules were actually ingested by the cells and lay scattered as blue pigment grains in their interior. In fact, we had succeeded in feeding the pus cells with indigo and had produced an *intra vitam* staining. Two explanations are possible. Either the material had entered the blood or lymph stream and had been ingested by leucocytes or phagocytes which had then migrated into the abscess, or the pus cells had ingested the granules *in situ* in the abscess, after the pigment had been carried thither up the Fallopian tube. This will, I believe, prove to be the true explanation and also carries with it the interesting fact that pus cells, as such, after their entry into an abscess are capable of ingesting foreign particles into their interior. In the other three cases of double pyosalpinx examined indigo was found in the pus in the tubes but not in the cells. Now in these cases there was no manifest discharge of matter from the uterus, though the presence of the indigo in the tubes proves that the communication between the tubes and the uterus was still patent. In fact, I believe that this is the case in most, if not all, cases of pyosalpinx. Blocking, temporary and intermittent, no doubt occurs of the lumen of the tube on the uterine side, but bearing in mind how difficult it is, even by operation, to obliterate the channel by any means short of excision I think it very probable that some communication exists in most of these cases of secondary infection of tubes with purulent contents and that an occasional slight escape of pus occurs, with corresponding relief of intra-tubal tension. In fact, the whole subject of tubal regurgitation of uterine contents is very interesting. We know from the artificial production of hydrometra and hydrosalpinx in animals, under aseptic conditions, that regurgitation of the hydrometric fluid from the distended uterus is much prevented by the sudden deviation of direction which the tube takes in passing through the uterine muscular wall. At the same time, no opposition is encountered by the mobile spermatozoa in their upward passage. And we also now know, from the observations I have just described, that foreign particles of a suitable size if introduced into the vagina are habitually carried up the whole length of the genital canal in women. It is not absolutely necessary that the indigo should be inserted into the cervix, for if deposited in the upper vaginal vault it is still found occasionally in the tubes at the operation.

The question of the size of the particles is an important one. Particles up to the size of lycopodium grains are carried up but this seems to be about the limit, as I have found lycopodium (a very few grains) in one case only. This same upward current exists also in animals, for I have repeatedly found indigo particles in the Fallopian tubes of rabbits after insertion of the powder in the vagina. I wish also to record an observation at this point on the question of mucous currents in the oviduct of birds. After dusting indigo on the cloacal opening, or after insertion of the powder within the cloaca in fowls, the pigment was found, not only upon, but also sparingly incorporated in, the egg-shell and I have seen it in the vitelline membrane, thus showing that it had passed up the oviduct. Further observations are necessary to ascertain whether this occurs only at certain periods or throughout the egg-laying period. I feel sure, however, from repeated observations during intra-abdominal inspection of the fimbriated ends of the Fallopian tubes during the menstrual period that regurgitation of menstrual blood and mucus occasionally occurs from the abdominal ostium of the tubes; moreover, blood is sometimes found free in the pelvic cavity without symptoms and apart from any question of tubal pregnancy. In fact, I have no doubt that in many cases of dysmenorrhœa in young women the pain is really tubal in origin and is due to peristalsis of the tube in its effort to overcome this regurgitant wave. The pain, in fact, is due to tubal, not uterine colic.

Let us for a moment consider one other important fact, depending on the establishment of the presence of this upward, utero-tubal, mucous current. Those who are brought in contact with uterine cases know that gonorrhœal and puerperal poisons, although the most important, do not exhaust all the sources of tubal and peritoneal infection. The mere exposure of the upper vaginal tract to dirt, to lotions and ointments, to any substance surgically unclean, by whatever means introduced, has in many cases originated salpingitis and chronic endometritis, and I am not without hope that this picture of the constant upward mucous current which I have described may produce a greater sense of responsibility in surgeons and tend, perhaps, to check some of the indiscriminate curetting operations which are so fashionable and which (while the only treatment in some cases) in others only aggravate the troubles they are supposed to cure. Fortunately, the door, though open, is guarded by the watchful peritoneum. Foreign particles and fluids introduced, as it were, guttatim, by the tiny canal of the tube, if not too virulent, are at once incarcerated and rendered innocuous. But it should surely make us all most careful to know that any powdered substance we introduce into the os uteri will probably be found within 20 hours inside the peritoneal cavity.

[Mr. Bond described his observations on the presence of indigo in biliary fistulæ after it had been given by the month.]

THE URINARY TRACT.

We now pass to the consideration of the urinary tract, from the kidney to the bladder, and from the bladder to the surface, by way of the male and female urethra. We will consider the ureters first. Reverse infection of the pelvis of the kidney so frequently occurs from interference with bladder function by septic instrumentation that the ureter is universally regarded as the usual channel of infection and not the blood stream. When we come, however, to consider the manner of this ureteral infection the successive steps are not so clearly known. In extreme cases of marked obstruction to the outflow of urine from the bladder in which backward pressure of urine leads to dilatation of the ureters and in which the interior of the bladder has become infected, by instrumentation or otherwise, it is, of course, quite possible that the open water-way, by arrest or reversal of current, may explain the upward carriage of infective organisms. At present I have not had an opportunity of testing the transference of indigo to the pelvis of the kidney in these cases. The more important point, however, was, if possible, to determine whether, supposing that from any cause (such as the establishment of a renal fistula) the normal downward current of secretion from the kidney to have been arrested, whether in these circumstances any regurgitation of mucous stream occurs in the normal, or at all events, undilated and competent, ureter.

The following case has an important bearing on this point:—

Lumbar nephrectomy for cystic destruction of the kidney by calculus impacted in the lower end of the ureter.—The calculus was detected by a probe in the ureter at the time of the nephrectomy, but the condition of the patient was such that it was thought wiser to bring the open end of the ureter to the skin surface in the loin and remove the calculus at a later date through a vaginal incision. This was done one week later and a good recovery ensued. After the operation of nephrectomy the bladder was irrigated daily and two drachms of an iodoform emulsion containing sterilised indigo allowed to remain in the bladder. The fistulous opening of the ureter on the loin was lightly plugged with a little white sterile gauze. This and the muco-pus from the ureter were examined daily and on three occasions numerous indigo particles were found showing that here, at all events, a reverse mucous current had passed up the ureter in the absence of any urine.

The position, then, at present is probably this: Given an arrest from any cause of the normal downward current of urine along the ureter it is possible that a backward mucous current may occur, carrying with it any infective organisms or foreign particles, such as pus, or blood cells, or débris, which may be present in the bladder. What we do not at present know is whether this regurgitation occurs in those cases of kidney infection in which there is no direct evidence of arrested secretion. We are not at liberty to assume, however, that even in such cases temporary arrest does not occur. It is, indeed, known that the flow of urine from the ureteral orifices is intermittent in normal circumstances; it is possible that this intermittency may be increased to the point of temporary arrest under pathological conditions. We still have to consider the question of the entrance of infection into the bladder from outside; the conditions, in fact, of the mucous currents in the urethra.

I will first consider the male urethra. The conveyance of infection from the exterior, in the absence of any outside interference, with a normal flow of urine along a healthy urethra is, of course, practically unknown. But, as in the case of the gall-bladder, the frequent performance of suprapubic cystotomy for surgical purposes in the urinary bladder affords opportunities of investigating what goes on in the urethral mucous canal. I have investigated two cases of suprapubic cystotomy in which the bladder was drained by Sprengel's pump after prostatectomy.

Complete prostatectomy.—Oct. 20th, 1904. Bladder drained suprapubically by Sprengel's pump, blood was present in urine for ten days, then clear. On Oct. 31st, ten days after operation, indigo was inserted within the urethra a quarter of an inch from the meatus in the eye of a Jacques's catheter, and again two days later. The urine drained suprapubically was collected daily and the sediment examined. Indigo grains were found sparingly in the deposit.

Noticing the difficulty in finding such a minute quantity of indigo in such a large quantity of fluid and the labour involved in searching for it, in the next case I adopted a somewhat different technique.

Prostatectomy for adenomatous prostate and suprapubic drainage of the bladder by Sprengel's pump.—March 2[illegible]th, 1905. The urine remained blood stained for one week after operation but when clear, eight days later, a little sterilised indigo was inserted into the penile urethra just within the meatus on one occasion only, no urine having been passed per urethram. A small piece of white sterile gauze was placed at the bottom of the suprapubic tube or silver cannula and this served as a filter through which the urine and vesical mucus passed before being drawn out by the aspiration of the small inner glass tube through the suprapubic opening. The gauze was removed 24 hours later, and a cover-glass preparation taken of the mucus and urine which it contained. Bright blue indigo granules were freely found in varying sized particles.

Now, since all source of accidental contamination from outside was avoided by a dressing over the suprapubic opening, the indigo can only have gained access to the interior of the bladder by traversing the urethral canal. Further, we must remember that in both these cases no instruments had been passed and that the urethra was uninjured, at any rate up to the triangular ligament and prostatic portion. The main point, of course, being that all passage of urine had been arrested for some days along the mucous canal. I have also tried inserting indigo within the urethra alongside of a catheter retained in the urethra and bladder, *in cases where it has been necessary* for surgical reasons for some days to drain the bladder through a tied-in catheter. In several of these cases I have recovered the indigo from the urine flowing from the catheter, showing that the material has passed centripetally along the urethra to the bladder. I do not feel, however, that much stress can be laid on this, as there is always more or less to and fro, or inward or outward, movement of any instrument tied in the bladder, it tends to be expelled and is passed back again and re-secured, as the movements of the patient alter its position and it is thus quite possible that, by friction of the instrument against the wall of the urethra, any material might be mechanically conveyed, in successive waves, along the urethra to the bladder.

This objection does not, of course, apply to the previous cases in which no instrument was used; but, at any rate, the experience of the latter case shows how easy it is for infection to be conveyed from a dirty meatus alongside a retained instrument into the bladder; for if inorganic particles can float, as it were, in the mucous stream which is set up between the instrument and the urethral wall and are carried thus backwards into the bladder infective organisms can do the same. It is not necessary to assume that they must be conveyed on the point of, or by, a dirty instrument; they may reach the bladder by way of the urethra from the surface at the meatus after the introduction of the instrument. In fact, surgeons know well that even though the urine be received by a tube direct from the catheter into some antiseptic fluid without contact with the air, yet it is practically impossible to keep the bladder aseptic for any length of time *in cases in which an instrument traversing the urethra is* tied in the bladder, and I think the above observations throw some light on the manner in which, and the route by which, this infection is brought about. At any rate, they point to the extreme importance of guarding the external orifices and probably careful disinfection of the external meatus and the application of efficient antiseptic filtering dressings at this spot would have a good influence in preventing bladder infection in the manner above described, especially in those cases (and they should be very few) in which it is necessary to tie an instrument in the bladder.

One word as regards the short female urethra. In one case of vesico-vaginal fistula with a very considerable opening, in which it was necessary to perform suprapubic cystotomy and operate from within the bladder, the opportunity afforded by subsequent suprapubic drainage was utilised to trace the urethral mucous stream in the female urethra. A little indigo was inserted just within the meatus and a small filtering plug of sterile gauze inserted in the suprapubic tube through which the urine was draining. Indigo granules were found in the mucus coating this plug when removed six hours later. We have thus traced the reflux passage of inorganic particles of a recognisable substance like indigo from the surface along the urethra to the bladder and from the bladder to the upper end of the ureter. In all cases the important associated condition has been that the normal flow of urine has been diverted. We still require observations on cases of pyelitis made at the time of operation, when the pelvis of the kidney is first explored and in which indigo had previously been inserted into the bladder. Observations on animals will probably be necessary to investigate this point under conditions in which no previous diversion of the urinary flow has been brought about by surgical operation or disease. The mode of infection of the epididymis by the tubercle bacillus or by the gonococcus or pyogenic organisms requires further examination. I have not yet been able to test the mucous current in the vas deferens, but I think it likely that sterilised indigo inserted into the prostatic urethra in suitable cases will be recovered from tuberculous and other abscesses in the epididymis or the vesiculæ seminales. If this should occur then the mucous canal of the vas deferens and not the blood stream will probably be the route taken.

RESPIRATORY TRACT.

With regard to the respiratory tract and the mucous canals in connexion with it, the accessory nasal cavities, the Eustachian tubes, and the bronchi, any observations on this part of the body are all, of course, open to the obvious objection that foreign particles may be, and no doubt are, carried by the air currents and distributed over the mucous surface. I should, however, like to mention one case of chronic otitis media with tympanic perforation in which sterilised indigo was insufflated for four days into the retro-pharyngeal cavity. The *muco-pus flowing from the external* meatus was collected on both sides and on the fourth day showed abundant indigo granules. Of course, it will be objected that owing to some effort of sneezing or blowing of the nose the material was transported up the canals by a blast of air. The patient was instructed to avoid all such sudden expiratory efforts and I am inclined to think that the presence of the indigo in the internal ear is not due to this cause. Supposing, however, that such is the case, it is surely a matter of considerable importance that in, at any rate, cases of perforated drums not only air currents should pass habitually from pharynx to middle-ear but that foreign particles should also find their way up to the Eustachian tubes in the absence, of course, of all instrumentation. The bearing of this on the question of conveyance of infection from pharynx to middle-ear is obvious, though, in the case of tympanic perforation, the important condition of diverted flow is present.

GLANDS.

We now pass to the consideration of the glands with ducts opening on to the surface of the body and the possible conveyance of pigment particles along the ducts, from the skin to the alveoli of the glands. The mammary gland, with it numerous ducts opening on the nipple, is the largest an most important of these glands. In a case of duct cancer the breast for six days before removal of the breast sterilise indigo was rubbed on the nipple twice daily and a simpl dressing of wool was worn. Great care must, of cours be taken to avoid contamination of the exposed breas tissues at the time of the operation, but this, after all, is a *object lesson in surgical technique and the same precautio* in the way of repeated washing and sterilisation of the skin which are taken to prevent contamination by skin organisms will apply to the indigo also. In order to insure absence of contamination I have either coated the nipple and surrounding skin to be excised with a layer of gauze and collodion or, having turned up the flap of skin to be excised, inwards all round the nipple, I have tied this by a purse-string suture, thus leaving only the raw surfaces exposed. The whole breast after removal is laid on a slab with the deep surface uppermost and incisions are made into the breast tissue in the neighbourhood of the ducts and into the portion affected by the cancer. Scrapings were taken from these incisions and indigo granules were found sparingly but from several parts of the breast. Other cases of mammary cancer have yielded the same result. I have also examined unstained sections of breast tissues obtained in the same way in two cases of cystic disease associated with chronic mastitis in which indigo had previously been applied to the nipple and detected it in the breast. In a case of chronic mastitis with a scirrhous nodule in one part of the breast, in which indigo was applied for four days before operation, the pigment was found in the portion of mammary tissue containing the ducts just beneath the nipple, but not in the solid portion invaded by growth.

Now, the importance of this fact, of the conveyance of pigment particles from the skin to the deeper parts of the mammary gland, along the lacteal ducts, lies in its application to the question of the transference of infective organisms by the same route. Here, again, it is a question of conveyance by blood or lymph stream as against transference by mucous *currents along the ducts, and it seems to me* that the demonstration of the passage of inorganic pigment particles by this latter route strongly confirms the suspicion that it is by these duct channels that pyogenic and probably tuberculous organisms gain access to the mammary gland. I feel some hesitation in the present unsettled state of the cancer problem in mentioning cancer in this connexion. All I will permit myself to say is this: that if, in the course of future research the exciting cause of cancer shall be proved to be parasitic, the above observations may stimulate inquiry into the nipple route as a possible channel of infection in cancer of the breast.

CONCLUSIONS.

We have now passed in review the conditions present in the more important mucous canals and gland ducts opening in the interior of the body and in one case in the ducts of a gland opening on the skin surface, and a few general observations bearing on the facts so observed may not be out of place. I think from the observations I have described we may consider it proved that by some means or other, and under certain conditions, particles of an insoluble substance, such as indigo, inserted into the orifices of a mucous canal or duct are conveyed along the mucous channel in a reverse direction to that taken by the contents of the tube, or by the secretion or excretion of the glands along such ducts. The conditions which seem to favour this passage are: some interference with the normal flow of the contents of the mucous tube or duct; some arrest or diversion of secretion, such as is produced by a fistulous opening, though it is by no means necessary that this should be complete. By what agency is this transference of foreign particles brought about?

Ciliary action.—Though present in the upper generative tract, cilia are absent in the lower genital tract, in the intestinal canal, in the biliary ducts, in the urinary tract, and in the ducts or glands opening on the skin.

Muscular contraction.—No doubt irregular or reversed peristaltic contractions in the bowel, if present, would bring about the result. It is, however, suggestive that the ascent of the indigo up the colon is not prevented but rather accelerated by the increased downward peristalsis produced by purgatives. Reverse muscular contractions are as yet, moreover, unknown, or rather undemonstrated in the bile ducts, urethra, and urinary tubes, Fallopian tubes, or in the ducts of glands.

The phenomenon is not due to physical agency alone, such as capillary action. It is absent in the non-living tube. The transference of particles in empty tubes and ducts is one, and there are other reasons before explained, for regarding he mucus which coats the walls of the tube or duct as the ehicle in which the particles are carried. Further observaions are necessary to ascertain whether a reverse current— sort of mucous backwater—is present in all mucous hannels or whether it only exists where the normal outgoing urrent of secretion or excretion is interfered with. Such a ack current is probably present to a certain extent normally hough much increased by any agency, such as a fistula, which starts a flow of mucus from the other end of the canal. The essential conditions, then, seem to be a living tube the walls of which are partially, if not wholly, in apposition and lined by a mucous secretion, while the reversal of this mucous current is favoured by any condition (such as a fistula) which leads to arrest or diversion of the ordinary secretion of the viscus or gland.

The bearing of these remarks on the larger question of infection will be at once apparent. I am inclined to think that in some cases more attention should be paid to mucous channels as routes of invasion rather than to the lymph or blood stream. Thus I have spoken of the large share which such a mucous, as opposed to a blood, infection plays in the diseases of the female generative tract. The rapid ascent of the urethra by the non-motile gonococcus and the colonisation of deeper portions of the tube, apart from direct extension of growth and in the absence of instrumentation or injection, are thus explained. The ascending infections of the kidney by way of the ureter can also be investigated from this point of view. Our knowledge of the causes which produce biliary and urinary calculi is still very incomplete. The facts which point to the importance of diseased conditions of the mucous linings of the excretory tubes in favouring the deposition of concretions are of especial importance from this point of view. And bearing in mind the proved transference of particles, under certain conditions, from duodenum to gall-bladder and from urethra to ureter, I hope that further light may thus be thrown on these calculous diseases. In fact, the burden of my remarks points to the necessity for the active recognition of the importance of all communications between the efferent canals of the body and the external world and thus accentuates the value of personal hygiene and true cleanliness.

Gentlemen, I hope I have not wearied you with these remarks on what may be called surgical physiology and pathology. As I said at first, instead of pointing to new operations or improvements in surgical technique, instead of giving statistical tables indicating case-mortality after operations, I have tried to turn your attention the other way and to glean a few facts from the many opportunities which modern surgery affords, for the observation of fundamental processes of organic life. And yet, without the surgical revolution which we owe to a few great men and which has been one of the glories of our century, these life-giving operations would have been unperformed and the light which they have shed in many a dark corner of the human body would never have shone. Though the public (the mass of our fellow creatures) are only beginning to grasp, as yet very imperfectly, the all-pervading influence which medical and surgical science, and indeed all the sciences which deal with physical and mental efficiency, will assuredly soon exert in the life of the individual, the City, the Nation, and the State; yet it is surely fitting that we medical men, who know these things, should ever recall the services rendered to humanity by the Pasteurs, the Listers, the Kochs, and all those who have done so much to raise our calling to its present proud position—all those who have made these things possible. And how better can we show our gratitude to them than by strenuous individual effort, each of us, in spite of much distraction and scanty opportunity, to add one small fact to the store of garnered knowledge, to bring even one stone to the building of that glorious Temple of Health, the topmost pinnacle of which will only be finished when disease and suffering have been finally vanquished.

TEMPORARY FIXATION OF TESTIS TO THIGH.

A SERIES OF 25 CASES OPERATED ON FOR UNDESCENDED TESTIS.

By C. B. KEETLEY, F.R.C.S. ENG.,
SENIOR SURGEON TO THE WEST LONDON HOSPITAL.

THE plan of keeping down the testis after operation in this class of cases by fixing it to the thigh was first demonstrated by me in cases shown at the Medical Society of London[1] on April 16th, 1894. It has been practised and recommended lately by several distinguished surgeons, especially by Professor Rushton Parker[2] and Professor T. Annandale.[3] The latter fastens the testicle by a ligature to the skin of the opposite thigh, probably with a view to pull in the line of the inguinal canal. But the pull is quite direct enough from the thigh of the same side and in the latter case the patient himself can easily relax the tension by flexing the hip. Katzenstein of Berlin in the *Deutsche Medicinische Wochenschrift*, 1902, vol. xxviii., p. 937, described a case in which he fastened the testis to a pedicled flap of skin of the thigh instead of to the fascia lata. I think this is no improvement on my plan. I am indebted for the reference to a very excellent paper on undescended testis by Odiorne and Simmons in the Annals of Surgery for 1904, vol. xl., p. 962. But they have overlooked my cases published eight years before Katzenstein's. I do not believe that any surgeon practically acquainted with my plan would ever afterwards resort to any other. The first step is to free the cord and testis. In many cases this requires the incision of the external oblique used in Bassini's operation for the radical cure of inguinal hernia. There frequently is a congenital inguinal hernia to deal with in these cases and when there is not, incision of the external oblique is sometimes necessary to bring the testicle out of the abdominal cavity and to free it and the cord from deep attachments. It was from Lucas-Championnière's book on hernia published 20 years ago that I learnt the importance of dividing these adhesions and also the comparative ease with which the cord can be separated from the tunica vaginalis high up the inguinal canal.

The main incision I make is over the inguinal canal and the external ring. Two other skin incisions are made in the great majority of cases, one about one and a quarter inches long at the bottom of the scrotum and the other of the same size in the upper and inner part of the thigh adjacent to the scrotal incision. Before cutting the scrotal incision a bed should be made with the finger in the scrotum to receive the testis and the scrotal incision should divide all the structures down to this bed. Something, either a blunt instrument or a piece of gauze, should be passed through this scrotal aperture *immediately, or its different layers will* cease to be opposite one another. The thigh incision should expose the fascia lata.

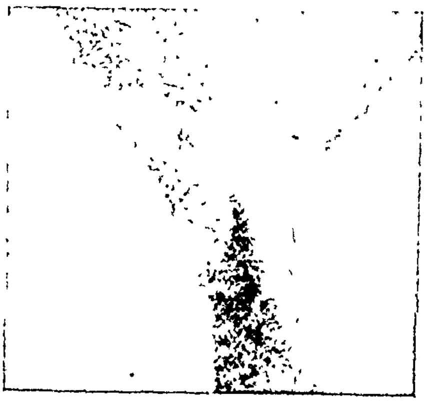
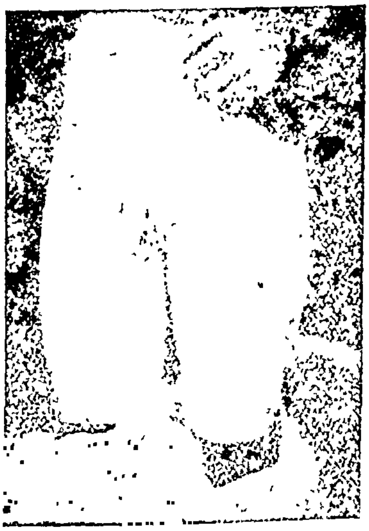
FIG 1



From a young man who had been operated on two years before for undescended testis and right inguinal congenital hernia. Being perfectly comfortable he did not wish the testis to be separated from the thigh.

The testicle and the cord having been thoroughly freed from everything but the musculo-fibrous bands forming the gubernaculum, which are generally attached to the pillars of the external ring, especially the internal pillar, the gubernaculum is divided as far away as possible from the testicle. A pair of forceps is then passed from below upwards through the hole in the scrotum and the gubernaculum is seized by it and pulled right through the scrotum till it can be seen through the hole in the skin of the scrotum. At the same time the tunica vaginalis testis should also be pulled down into the scrotum, though it is not absolutely necessary to keep the testis in its serous bag; indeed, I have often omitted to attend to this point. The posterior borders of the apertures in the skin of the scrotum and thigh are next united by a continuous silkworm-gut suture left long at both ends. Now the gubernaculum testis is sutured with strong catgut to the fascia lata of the thigh; and, lastly, the original silkworm-gut suture is used to complete the union of the skin apertures in the scrotum and thigh to one another. The hernia which is generally present is operated on for radical cure in the way the surgeon thinks best for the individual case. I nearly always do a Bassini's operation, but in very young children have been content with simpler procedures such as that of Kocher.

FIG. 2.



Testis attached to thigh; photographed just before separation.

Even when the testicle has been wholly intra-abdominal I have always succeeded, not only in bringing it into view chiefly by means of the gubernaculum but also in getting it, by persuasion, to come down to the fascia lata without uncomfortable or painful tension. The thigh can always, if necessary, be brought up to the testis by flexing the hip. The patient is sent to bed with his hip flexed but soon straightens it out himself, thus gradually lengthening a short cord, and I repeat that the process is painless. None of my cases have suffered from any complication except an occasional stitch abscess, due either to delayed dressing or omission to remove the silkworm-gut suture from the skin. For dressings is used iodoform gauze wrung out in 1 in 2000 perchloride solution, the gauze being passed behind the scrotum as well as in front, and over the gauze salicylic wool. If the urine wets this dressing no harm is done if it be changed within 24 hours. In older and clean patients it does not generally need to be changed at all until it is time to remove the skin sutures.

I like to leave the testis attached to the thigh for five months. It is rare to find a patient who feels any discomfort from this. One of the above illustrations (*Fig.* 1) is taken from a patient who had been operated on two years before and who, being perfectly comfortable, saw no reason for having the scrotum freed from the thigh. I have had several such cases. In some of the patients both testes were operated on, sometimes separately, sometimes together.

Occasionally I have attached the fibrous coat of the testis directly to the fascia lata and several times the fibrous fold between the lower end of the epididymis and the body of the testicle. But the gubernaculum is the best. Sometimes I have passed the gubernaculum beneath a bridge of fascia lata and then brought its end up again and sewn it to its base. There is an objection to fastening the testis too close to the fascia lata, as then the parts have afterwards to be dissected asunder. In the operation, as I generally do it, they can be separated with a scalpel or sharp pair of scissors, cutting close to the thigh, especially as the testis has a greater tendency to pull the fascia lata up than to be pulled down by the fascia lata. Two or three stitches serve to close the wounds made by the separation, which is effected under local anæsthesia. When I have found no tension at all on the cord and testis I have simply carried the suture fixing the gubernaculum through the bottom of the scrotum with a needle and with the same needle sutured it to the skin of the thigh only, dividing it when removing the skin sutures. But I have only once found the tension so non-existent as to justify this.

The testis generally remains permanently in the scrotum but near its root. The fears about a testis just outside the inguinal canal and on the front of the os pubis being dangerously exposed to injury are according to my observation, and I have inquired carefully into this point, imaginary. For example, one of my patients has had his testis in that position for ten years, playing cricket and other games without the slightest inconvenience.

Do these testes grow when brought down in the scrotum? Undoubtedly some of them do, but not to the size of normal testes. Reproductions of photographs are given of two cases (Figs. 1 and 2). The scrotum and testicles represented in *Fig. 1 had been attached to the thigh two years* and the patient was perfectly comfortable, wishing it to be left alone.

Should the undescended testis be brought down by operation? Ordinarily, if an important organ were out of place and could safely be put into correct position, the indication for operating would be regarded as sufficient. Moreover, that indication would be strengthened if there were reason to believe that not only appearance but function would possibly be improved. Now this is true of the testicle. But there is still another reason for bringing down an undescended testis by operation—namely, that in such a case all the most serious and expensive features of the operation may be required to treat the frequently coexisting hernia.

There are some who advise that when an undescended and small testis occurs in connexion with a hernia, then the testis should be removed. They say it is worthless. The burthen of proof of this view lies with them. I think they have quite failed to sustain it. Even if it be granted that microscopic examination proves such testicles to be incapable of producing normal spermatozoa—and I doubt if it does, even then, however, the microscopic examination of a testicle just removed from the inguinal canal or from the abdominal cavity does not afford any final proof of what that testis might have developed into had it been brought down into the scrotum and kept there for several years. Moreover, there has been known to us now for several years still another strong reason for conservatism in dealing with undescended testes—viz., the fact that other glands, such as the thyroid, the suprarenal, and the thymus, exercise a serious influence on the general state of the body in some more or less uncertain way, generally regarded as by producing an internal secretion.

This last argument has of late been unwittingly misrepresented and weakened. It has been put as if it depended on the truth of a quite unproved hypothesis—viz., that which assigns the duty of influencing the general state of the body to certain cells in the testicle of which the function is as yet unknown. This is an interesting surmise, but the argument in favour of preserving as much testicular substance as possible is quite independent of it and must not be regarded as standing or falling with any such speculation. It is quite conceivable that the internal testicular secretion, if there is one, may be a mere by-product of the manufacture of semen.

Lastly, it should always be remembered that each individual has only two testes. And further, sometimes both are undescended. Such cryptorchids are said to have begotten children, though I am not aware whether the evidence in favour of the statement was very severely tested. There are obvious possibilities of error. So far as I know, only one of my patients has married and become a father. But nearly all my patients are still more or less young. Reflecting on the reasons which have brought most of my patients with this affection to consult me, I think they have been one or more of the following: (1) liability to attacks of pain, sometimes very severe, in the inguinal region; (2) the mother's concern at discovering the absence of the missing testis; (3) the coexisting rupture; and (4) acute strangulation of a congenital hernia which perhaps had given no sign or warning until the day of strangulation. With regard to No. 1, it may not be possible to tell whether the pain is due to a hernia or to the nipping of the testis as it slips in and out of the canal.

In some of my earlier cases in which I have found no hernia I think I may have overlooked a potential one through not slitting up the inguinal canal. With care an unobliterated process of the tunica vaginalis should usually be found in the inguinal canal. Two, at least, of the cases reported in this paper came under my care while acutely strangulated. One, a young man, was quite unaware that he had a hernia; the other, an old man, had his gubernaculum directed outwards after emerging from the external ring and attached to the front of Poupart's ligament, not far from the anterior superior iliac spine. The 25 cases on which this paper is based were tabulated for me by Dr. W. Trethowan, now of Perth, Western Australia, and by Dr. E. Bell Tawse. They stop short four years ago since which I have operated on a number of other similar cases. However, as all have followed practically a similar course ending in a good recovery, it is not necessary to complete and to publish the tables. Analysed they show—

Right side affected in	12
Left ,, ,,	2
Both sides	5 (1 ?)
Not stated	5
Total	25

The presence of hernia was noted in ten, but a potential hernia—i.e., an unobliterated tunica vaginalis in the inguinal canal—existed in nearly all the rest. In two cases the hernia was strangulated. One hernia (in a man aged 61 years) had a part of the bladder in the inner wall of the sac. In this case already mentioned the testicle had emerged from the inguinal canal and then passed upwards and outwards to be fixed near the anterior superior iliac spine, where there was also a hydrocele. It occurred 17 years ago and I removed the testis. On the earlier cases Macewen's operation for hernia was performed, on most of the later, Bassini's. As regards temperature, in only three is it noted to have risen above 100° F. after operation, in only one above 101°, and in not a single case did it rise to 102°. In the great majority the highest point was 99° to 99·6°. In seven cases the charts are missing.[4]

Grosvenor-street, W.

ON THE TREATMENT OF ACUTE SUMMER DIARRHŒA IN INFANTS.

By J. A. COUTTS, M.B. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

THE theme of acute infantile summer diarrhœa is a somewhat dispiriting one, nor is the depression so commonly associated with recollections of it at all relieved by a sense of any conspicuous success in its treatment. It is, nevertheless, an important complaint both from its extreme prevalence and for the large share attributable to it in our excessive infantile mortality.

Any form of diarrhœa may occur in infants during summer weather but the particular one I am dealing with is only too readily recognisable without any further specifying or description. Occurring in widespread epidemics when the weather is unduly warm it floods the out-patient department and the wards of every children's hospital and its treatment exacts the major part of the time and attention of both the resident and the visiting staffs. The complaint is known under various names, the two commonest, perhaps, being cholera infantum and acute gastro-enteritis. To both such names, however, there are objections, in that the one implies a connexion with another totally different and distinct disease and the other assumes a pathological condition of the stomach and intestines which is seldom, if ever, verified on post-mortem examination. The symptoms are apt to prove monotonous in their unvarying sameness, being mainly comprised in sudden onset, with vomiting and diarrhœa, speedily followed by profound collapse. One feature, however, distinguishes the complaint from all others ordinarily occurring in these climes and this is the rapidity with which the tissues are drained of their fluids and thereby a healthy infant is reduced in a very few hours to a wasted one with wrinkled skin, depressed fontanelle, sunken eyes, cold breath, and almost inaudible cry.

As an instance of the completeness of this tissue drainage, I may quote a remarkable case that occurred many years ago in the practice of my colleague, Dr. Eustace Smith. This case was that of an infant with chronic hydrocephalus, who was admitted into the Shadwell Hospital with acute summer diarrhœa. In the course of the last complaint the cerebral ventricles became drained of their distending fluid, with the result that both brain and vault of the skull collapsed upon their bases and, with the infant in a vertical position, half a pint or more of water could have been poured into the concavity produced in the skull and there retained. Oddly enough, doubtlessly owing to the integrity of the more strictly vital centres in the medulla, the infant lived for several days in this condition, and at the post-mortem examination the only remains of the brain were a shapeless disintegrated pulp on the floor of the skull. The severity of the drainage of the tissues and the importance of this element in the complaint may be readily gauged when even the cerebral ventricles can be emptied of their normal fluid.

Another point in the disorder may be briefly touched upon from its extreme importance in prognosis and this is the presence or absence of pyrexia. In every case probably the temperature is raised at the start and sinks below the normal in the condition of collapse. Recovery from the last is usually accompanied by a temporary rise of temperature above the normal. Cases where this rise persists and cases where the temperature remains high without the occurrence of collapse are of infinitely graver prognosis than those in which the temperature is normal. It has been pointed out that the heightened temperature may persist when both diarrhœa and vomiting have practically ceased, showing the toxæmic nature of the complaint. In my opinion too little stress has been laid upon this question of pyrexia, and given a normal temperature I seldom despair of pulling an infant through.

---

[4] Three patients operated on were shown at the Medical Society of London on Jan. 2[illegible]th, 1903. In one of them, operated on nine years before, the testicle had certainly grown. It had the testicular sensation markedly. (Transactions of the Medical Society of London, vol. xxvi., p. 322.)

The main lines of treatment are the same with all of us and the subject indeed does not permit of novelty. My present object is to discuss briefly such of the ordinary measures as I have found most useful in a practice where I have had only too many opportunities of treating the disorder. When seen in the early stages there can be no doubt as to the wisdom of the usual practice of giving a purgative and temporarily withholding all milk. Such measures will usually cure the milder forms of diarrhœa which in hot weather are apt to drift into the severer one at present in question. Occasionally, too, these same measures may be sufficient to cure cases of the acute form when taken early enough. The purgative commonly given is castor oil, and in the milder varieties of diarrhœa this acts admirably. In the acute form I prefer calomel for the following reasons. When vomiting is present castor oil is not likely to be retained, but there is a possibility of calomel being so, and in this last event the drug may be of service in the vomiting itself. In a small minority of cases the diarrhœa is unaccompanied by vomiting, and in such cases castor oil may induce vomiting and so add a further gravity to the complaint. Calomel, moreover, may act as a slight intestinal antiseptic, either from the products into which it is converted before absorption or from the action of any bile it may transfer from the duodenum into the lower bowel. Further, it may act indirectly as a diuretic, a consideration of no small importance where the renal functions are inefficient or wholly in abeyance. The chief use of the calomel is, of course, to clear the intestine of any deleterious material and to check vomiting, but the subsidiary advantages attaching to it, slight as they may be, should not be overlooked in a complaint where assistance of every kind is so urgently needed. As I have said, there is no question as to the value of a purgative, calomel or otherwise, at the start of the complaint, when the temperature is usually high and the tongue furred. When, however, the vomiting and diarrhœa have persisted for some time and where milk has not been administered or not retained, then a purgative is of doubtful advantage or possibly even harmful.

There is no remedy that has any influence over the disease as an entity and the main treatment is that of the symptoms —vomiting, diarrhœa, and collapse—with careful regulation of the diet when food is resumed.

In the great majority of cases vomiting is the earliest symptom, usually preceding the diarrhœa by an appreciable interval. Fortunately, too, it generally ceases some time before the latter. It is, moreover, of more urgent importance, for whilst it persists no nourishment can reach the infant, the accompanying diarrhœa precluding any attempts at temporary and imperfect alimentation by way of the rectum. For the treatment of the vomiting I know of no remedy so successful as that of washing out the stomach with warm water or a weak solution of bicarbonate of sodium. This is most readily and satisfactorily done by means of a soft tube introduced through the nose. After washing out the stomach I often administer a tenth to an eighth of a grain of cocaine in a teaspoonful of iced water. In slighter cases the cocaine is sufficient by itself but in case of non-success after two doses I do not persist with its use. *Cocaine, indeed,* is a useful remedy for vomiting from many causes in children but its dose has to be regulated carefully. On two occasions I have seen symptoms which were taken to be those of cocaine poisoning from doses of one-fifth of a grain in children one year old.

The foregoing measures can be supplemented with safety by a mustard poultice over the epigastrium and the administration of a mixture of carbonate of bismuth and bicarbonate of sodium, along with a quarter of a minim of dilute hydrocyanic acid. The bismuth and alkali, moreover, aid in checking the diarrhœa as well as the vomiting, but to be effectual they should not be given in less than five grains of each to even the youngest infants. During the time of abstention from food the vomiting is relieved by giving frequent teaspoonfuls of hot water. The hot water is grateful, too, to the infant by relieving the excessive thirst and it helps to ward off collapse. The vomiting is generally most urgent at the onset of the complaint and usually subsides when the food is withheld. *It may recommence* when food is again resumed and the latter should only be given in very small quantities at frequent intervals. If, in spite of these precautions, the vomiting recurs with food, then the latter should be given entirely cold or even iced if necessary. I have frequently met with a hesitation about administering such cold food to infants, mainly based on the ground that it is unnatural at such an early age. To this objection it may be answered that neither artificial feeding nor acute diarrhœa is a natural condition in infancy and unnatural states may have to be met with unnatural means.

The number of drugs that have been advocated for the treatment of the diarrhœa is legion and their very number is proof of their general inadequacy. By trustworthy authorities resorcin, naphthol, salicylate of sodium, salicylate of bismuth, salol, carbolic acid, tannigen, and numerous other drugs have been advanced as almost specifics, but trial of most of them would not lead me to place any great reliance on any one of them. Regarding one class of drugs, the direct astringents, I concur in the general agreement that they are of little or no value in the early stages of the disorder. They find their usefulness in the more chronic diarrhœa that is so often left by the acute disease. When the motions are peculiarly offensive, a not very frequent occurrence in the acute stage, I have found benefit in a mixture containing a minim each of glycerine, of carbolic, and tincture of iodine. This usually corrects the fœtor of the motions in a day, or a couple of days, and when this has been accomplished other measures for controlling the diarrhœa are much more effectual. For the ordinary run of cases I have found nothing more useful than half grains each of grey powder and Dover's powder, given every four hours, alternately with the bismuth mixture mentioned above. After the acute stage is passed, but where diarrhœa persists, if there be no tendency to vomiting, I usually prescribe oxide of zinc and have found this last quite as effective as, if not more so than, the astringents more commonly employed. Along wit continue the powders of mercury with Dover's powde

In the cases with continued pyrexia few succe attained with any treatment. For these I have now co rely on small doses of calomel, an eighth to a tenth grain, with an equal quantity of Dover's powder, given two or three hours, and fancy I have been more succe or less unsuccessful, with such treatment than with other. Here again, too, the wet pack has occasio seemed a valuable addition to the other measures. I cases where the diarrhœa persists a daily irrigation o large bowel with saline solution for three or four day often apparently been of advantage.

In a great many instances the infant is already in a of collapse when first seen and this has to be dealt promptly, independently of the other conditions associ with it. The readiest and most efficacious remed the one most commonly employed, an injection of str nine, and latter-day experience shows that infants collapse will bear much larger doses of the drug were formerly considered either safe or desirable. one occasion an infant, aged ten months, under care in hospital was given as much as two mi of liquor strychninæ by injection. The result was that was desirable; but in spite of this and of the *that bigger doses may succeed* where smaller ones I still think the dose in this instance to have been too l and would not counsel more than one minim for an in of the age in question but would repeat this after a s interval if necessity arose. The strychnine injection can followed by a mustard bath with great and conspic advantage. In the slighter degrees of collapse a strych injection may not be essential, the mustard bath in it being all that is needed. The bath is beneficial in ways: in the first place it is a powerful general sti lant and restorative; in the second, by its local ac it may help to restore the functions of the skin which ar abeyance. The return of sweating is a favourable sign often an early one of impending recovery. After the must bath it is well to wash out the lower bowel with a pin normal saline solution, at a temperature of 105° F. T should be slowly injected, by preference with an irriga but there is no need to use a long tube. This procedure be of service in several ways. It helps to clear the la bowel of any irritating or infectious material that may t to increase the existing toxæmia. Given in the manner dicated, the solution is usually retained for periods vary from half an hour to two hours. Thus some of it is absor and by assisting to restore to the tissues the fluid of wh they have been drained the rectal injection become powerful restorative in the collapse. The hot fluid, aga is of advantage in raising the temperature which may have fallen many degrees below the normal. In states of exhaustion in infants, from any cause, a large warm rectal injection acts as a sedative and will often induce sleep when other means have failed. After the return of the major portion of the injection I am in the habit of advising the employment of a second smaller one, of from three to four ounces. This is usually all retained and often its benefit is speedily shown in an improvement of the pulse. To this second smaller injection can be added any alcoholic stimulant that may be deemed desirable, when vomiting prevents it being given by the mouth. These smaller injections can advantageously be repeated every three or four hours. The other measures can also be repeated if necessary but the collapse when once thoroughly recovered from seldom recurs. Some writers have claimed a remarkable success in the treatment of the complaint by frequent washing out of the stomach and rectum by the methods which I have mentioned. My experience has not been confirmatory of the advantage of such repetition of the measures and I now restrict their employment for the times and purposes already given.

In every stage and condition of the complaint the question of feeding is of paramount importance. There can be no doubt as to the wisdom of the ordinary course of withholding all food during the first 12 hours, or even longer if the state of the infant seems to admit of it. During such time the administration of hot water, mentioned when dealing with vomiting, can be continued with advantage. If the condition of the infant be very urgent small quantities of white wine whey can be tried. This is often retained when every other substance with a resemblance to nutriment will be rejected. It should always be remembered, however, that the amount of nourishment in such whey is extremely small and the amount of alcohol is proportionately large for an infant. The marked improvement in the infant that often ensues from its administration in the early stages of the complaint should not, then, lead to a long continuance with it. Whilst all are agreed as to the advisability of discarding cows' milk at the commencement of the complaint there are differences of opinion as to the appropriate time for its resumption and as to the substitutes to be given for it in the interval. In nearly every case the milk has been directly responsible for the disorder, either through the introduction by its means of bacteria or their products or through its forming a suitable medium for the conversion of the ordinary saprophytic organisms of the intestines into others that are harmful and pathogenic. Clearly, then, on its resumption the milk should be sterilised or pasteurised, as, indeed, it should be throughout the continuance of unduly warm weather. Unfortunately, however, many infants in ill-health have a repugnance to sterilised milk, when not previously accustomed to it, and in such infants sterilised milk will often cause vomiting or be refused. Apart from these considerations, in the early stages of the complaint the digestive system is so disturbed that it is usually totally incapable of dealing with cows' milk at all, and given at such times even sterilised milk may serve as a mechanical source of irritation to the intestines and so prolong the diarrhœa. The digestive organs share in the general and profound inanition which the complaint entails and must themselves be nourished to enable them to perform their functions properly, and how to accomplish this is a main source of difficulty. No assistance is here forthcoming from the use of predigested foods, such as pancreatised or peptonised milks. Such milks are apt to cause looseness of the bowels in healthy infants if too long continued, and under the conditions at present in question the risk is great that under their use the diarrhœa may re-start or be prolonged. The commonest substitutes for cows' milk in the early stages are veal or mutton broth, albumin water, and raw meat juice. Their usefulness at such times is indubitable, but they should not be employed for longer than 24, or at the most 48, hours. I have, it is true, known infants to be kept alive on such substitutes for a much longer time where cows' milk has disagreed but in no single instance have I known a child under such conditions gain weight or in any way be considered to have thriven. Most of them, indeed, died from a slow inanition. Of these substances, the highest in nutritive value is raw meat juice and a fresh home-made preparation is preferable to any of the much-advertised proprietary articles. But any raw meat juice, given in such quantities as to have any real effect in the nutrition of an infant, is apt to give rise to foul, tarry motions after a few days use, a contingency that is far from desirable. Rather than continue for longer than two days with either meat broths or meat juice I would give a trial to one of the patent foods, such as Mellin's given with whey, &c. It is only in emergencies, like the one at present in question, that I have found even an occasional temporary use for such foods. It is very rarely, indeed, that I employ them and I find a good brand of unsweetened condensed milk is far preferable to any one of them. Such a milk is sterile when first opened, is fairly easy of digestion, and when diluted with three parts of water the solution approximates in nutritional value to that of average cows' milk. I usually start with a very dilute solution, one part of the condensed milk to four parts each of barley-water and lime-water, and slightly sweeten, the excess of alkali being useful in the presence of diarrhœa or vomiting. If this is retained and digested the strength of the solution can be increased and after a few days a start can be made gradually to replace the condensed milk by boiled or sterilised cows' milk. If the infant is taking the unsweetened condensed milk well no anxiety need be felt if this substitution cannot be carried out at once, as I have known many infants to be fed with it during the whole of the hot weather or even during many months and still thrive fairly well. But of course a long continuance with it is not to be commended as it is attended with the risks of the probable contraction of rickets and the possible one of scurvy as well. In the difficulties associated with the acute diarrhœa of infants, however, I have found the temporary employment of such milk of the greatest advantage. Many chronic diarrhœas in infants, too, are immediately benefited by the substitution for a few days of unsweetened condensed for ordinary cows' milk. There is a perfectly intelligible prejudice on the part of the profession against condensed milks generally, founded mainly, I believe, on a knowledge of the sweetened brands, most, or all, of which have been righteously condemned. My own preference as to a substitute food for infants is for properly modified fresh cows' milk given, in most circumstances, neither boiled nor sterilised. No unsweetened condensed milk is an ideal food or should replace ordinary cows' milk as a stable one for hand-fed infants, but a temporary trial of a good brand of it can be recommended under the conditions I have indicated. In every case, however, whenever practicable the sooner cows' milk replaces it the better for the infant.

The age of the patients and the severity of the complaint must render the mortality a high one, let the treatment be as prompt and as well devised as possible. Still, the extreme prevalence of the disorder is to be regretted, as it is in a large measure a preventable one, and this with the simplest precautions. As regards the etiology of the complaint, three factors are prominent in the vast majority of cases—the infantile age, hand-feeding, and the presence of unduly hot weather. Severe diarrhœa and vomiting, speedily followed by collapse, can indeed occur in infants at the breast. But such cases are rare compared with the number occurring in the hand-fed and whether all cases are etiologically identical is open to question. One frequent cause for the disorder, then, lies in the food administered and this is, without doubt, the one usually assigned for it—the more thorough bacteriological contamination that cow's milk undergoes in excessive heat. It follows, then, that in hot weather all cows' milk for infantile use should be boiled or, better, sterilised. Whether such boiling or sterilisation of cows' milk should be carried out as a routine practice in all cases of hand-feeding is, however, another question. A contributing cause is the innervating effect upon the digestive system that excessive heat entails and both breast fed infants and adults share with the hand-fed the tendency to simple diarrhœa during summer weather. In many cases of the acute disorder there is a history of its having followed on a simple diarrhœa of no great severity. During the hottest months, then, it is well to lengthen the intervals between the breast-feedings and in hand-fed infants slightly to lessen both the quantity and strength of the cows' milk meals administered. In both classes any discomfort which the infant might suffer from the reduction in his food can be met by small quantities of plain water being given between the meals.

Lastly, no diarrhœa, however slight, in infants during the summer heat should be lightly regarded and still less be considered as even salutary. A castor-oil purge and the withholding of food for a few hours will promptly cure most of such simple cases and prove a safeguard against the acute disease. The few simple measures mentioned will, I believe, if carried out in summer weather, lead to a large reduction in the number of cases and their attending mortality.

Upper Berkeley-street, W.

AN ANALYSIS OF 300 CONSECUTIVE GYNÆCOLOGICAL LAPAROTOMIES.

By ARTHUR H. N. LEWERS, M.D. Lond., F.R.C.P. Lond.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

PART II.[1]

The remarks forming the whole of this part of the paper were originally incorporated in the table itself, but it was found more convenient to print them separately. The numbers are the same as in Part I. and it may be repeated that the cases are *absolutely consecutive;* every case is included in which the author performed abdominal section during the period of time referred to in Part I. It will be apparent that the remarks on each case should be read in conjunction with the other particulars of it given in the table in Part I.

Remarks.

Case 1.—A multilocular ovarian cyst of the left ovary of the size of the uterus at full term. The tumour had been tapped on five occasions before operation. It contained thick, brown, soapy fluid. The right ovary was healthy. The peritoneum was washed out with normal salt solution twice. There were firm and extensive adhesions, parietal and intestinal.

Case 2.—Removal of uterine appendages. Pelvic adhesions were found.

Case 3.—A tumour of the right ovary of the size of a goose's egg. The left ovary was healthy.

Case 4.—A right ovarian cyst of the size of a large walnut. It burst on pulling it up and about one drachm of pus escaped.

Case 5.—The chief symptom was a constant desire to pass urine with difficulty in passing it. There were multiple fibroids, one especially occupying Douglas's pouch. One ovary was not removed.

Case 6.—The patient was operated upon for cancer of the cervix by supravaginal amputation of the cervix. The opening contracted and it finally closed, causing hæmatometra and double hæmatosalpinx of the part of the tubes immediately external to the uterus. The uterus was dilated to the size of one four months pregnant. An attempt was made to enter the uterine cavity from the vagina; a large vessel was wounded in trying to do so, probably a uterine artery. The hæmorrhage was imperfectly controlled by pressure while preparations were made for abdominal hysterectomy. Both ovaries were cystic and were adherent in Douglas's pouch. The vermiform appendix was adherent to the dilated uterus. The patient seemed fairly well at the end of the operation but had lost much blood previously and she died within 24 hours.

Case 7.—The right Fallopian tube was closed at its outer end and was dilated; it was adherent to the corresponding ovary. A cyst in the left ovary was punctured but the left ovary was not removed; the left Fallopian tube was healthy.

Case 8.—The tumours were both dermoids; that on the left side was of the size of a cocoa-nut and that on the right of the size of a hen's egg. Both were removed without opening the cyst wall.

Case 9.—The tumour weighed five pounds.

Case 10.—230 ounces of fluid had been [illegible] peritoneal cavity about a week before th[illegible] appeared clinically to be either malignant [illegible]

Case 11.—Chronic inflammation of th[illegible] present.

Case 12.—A fixed mass existed in the left iliac region and in the pelvis. It was thought possible that it might be a generally adherent ovarian or more probably a malignant mass. At the operation it was found to be a malignant mass involving, or rather imbedding, the sigmoid flexure. The bowel was opened before the relation of the mass was fully determined. The patient recovered from the exploratory operation but she died from malignant disease nearly a month later.

Case 13.—A large solitary fibroid weighing six pounds. The left ovary was not removed. Twelve days after the operation the patient developed acute mania and remained insane during the month that she was in the nursing home. Soon after she went home she was taken to Brighton and in a very short time all the mental disorder disappeared and she has remained well ever since. I saw her in 1904 and she was then quite well and following her usual occupation.

Case 14.—The left tumour was of the size of a uterus seven months pregnant. It contai[illegible] was adherent to the intestine extensively. [illegible] The right ovary, which was slightly cystic, w[illegible] gg; it also was removed. The peritoneum was washed out with salt solution.

Case 15. The uterus was enlarged by an interstitial fibroid of the posterior wall to the size of a fœtal head at term A dermoid of the left ovary of the size of an orange contained two teeth. The patient had had retention of urine twice before operation.

Case 16.—Tubal pregnancy on the left side causing a large extravasation of blood in the pelvis.

Case 17.—The tumour reached to the umbilicus. An interstitial fibroid in the anterior wall was undergoing mucoid degeneration; it was of the size of a cocoa-nut. There was a subperitoneal fibroid of the size of an orange attached to the top of the uterus; it was not degenerating. The left ovary was not removed. The right ovary was removed with the uterus.

Case 18.—The tumours re[illegible] ovarian tumour on each side. [illegible] old adhesions everywhere and [illegible] had to be removed in order to [illegible] were also adhesions which w[illegible] flexure that a hole was torn in [illegible] by a purse-string suture with Lembert's sutures over that.

Case 19.—This was an emergency case. The pulse was 144 before operation. An intravenous injection of saline fluid was made at the same time as the laparotomy. A fœtus of four months was found free in the peritoneum with a large amount of blood and recent clot. The peritoneum was washed out with saline fluid twice. The patient had had amenorrhœa for eight months till two weeks before admission when she began to have a red vaginal discharge.

Case 20.—A mass of fibroids reached to the edge of the ribs on the left side. The larger part of the tumour was formed by interstitial fibroids and was softer than the upper portion near the ribs. The left ovary was not removed. The right ovary was removed with the tumour.

Case 21.—There was free fluid containing jelly-like lumps in the peritoneum. The main tumour reached to the navel, rising from the pelvis. It appeared to be an ovarian tumour and was evidently malignant, as numerous isolated secondary nodules existed at various parts of the peritoneum—e g., that of the abdominal wall. The patient had had colotomy performed without benefit some time before.

Case 22.—Hysterectomy and ovariotomy were performed.

Case 23.—An ovarian tumour reaching up to the umbilicus with adhesions to the appendix and sigmoid flexure extensively and universally in the pelvis. As it was dissected up about four inches of the right ureter were exposed as if cleaned by a dissection. The cyst was so adherent to the uterus that the uterus had to be removed as well. No sign of the other ovary was seen. No peritoneum was available to cover the cervical stump.

Case 24.—The uterus was enlarged by carcinoma of the body to the size of a uterus two months pregnant. The right ovary was removed with the uterus; the left ovary was not removed.

Case 25.—The left uterine appendages were chronically inflamed, causing persistent pain. The right appendages were normal and they were not removed. There were pelvic adhesions.

Case 26.—The left uterine appendages were normal and were not removed. There were slight pelvic adhesions.

Case 27.—Fibroids. One large interstitial fibroid in the left side of the body of the uterus was softening in the centre; several smaller fibroids were not softening. The whole mass reached half-way between the umbilicus and the ensiform cartilage. The right ovary was healthy and was not removed; the left formed an ovarian cyst of the size of [illegible] the tumour. The mass was remove[illegible]

Case [illegible] sions, and a right hydros[illegible]

Case 29.—The patient [illegible] before the operation. Sh[illegible] were moderate pelvic adhesions.

Case 30.—A left ovarian tumour reached nearly to the umbilicus. Double uterus. Both uteri from the abdominal aspect were normal, except that each had only one set of uterine appendages to it. The left tumour reached forward from behind between the uteri and was adherent to the bladder. The right ovarian tumour was of the size of a duck's egg. The vaginal portion of the cervix was single. There were intestinal, pelvic, and vesical adhesions.

Case 31.—The tumour reached two inc[illegible] the uterus was enlarged by a single sol[illegible] posterior wall. On section the surface of [illegible] The mass removed weighed four pounds. The left ovary was removed with the tumour; the right was not removed.

Case 32.—Ovarian tumours of the size of a child's head a year old. They contained thin, brownish-black fluid. The right tumour wall was very friable. The peritoneum was washed out with salt solution. The patient was very stout; there was a good deal of distension for the first three days after operation.

Case 33.—Multilocular ovarian cyst of the right side reaching half-way up to the umbilicus. It contained brown fluid.

Case 34.—[illegible] escence was uninterrupted till [illegible] of temperature to 104° F. occurr[illegible] remained normal. No explanation of the rise of temperature was to be found but it occurred at about the time when the menstrual period was due. Pelvic adhesions were present.

Case 35.—The Fallopian tube removed contained a three months fœtus; the fimbriated end could not be seen. There was a good deal of blood free in the peritoneum.

Case 36.—Removal of the appendages.

Case 37.—The tumour reached to the umbilicus; it was the uterus enlarged by multiple fibroids.

Case 38.—The right tube formed a hæmatosalpinx; there was no blood in the peritoneum. The left Fallopian tube was dilated, thickened, and closed. A thin flake of this tube was left where densely adherent to the rectum. There was seen a curious short, broad, dense [illegible] testine and the sigmoid flexure. There [illegible] ilated, and thickened. [illegible] gradually rose. Some [illegible] As on Feb. 10th it [illegible] I called in a surgeon [illegible] rent across the seam [illegible] bowel above this was uniting the peritoneum [illegible] distended; all below was collapsed. The surgeon opened the bowel and put in a glass tube but the patient died three hours later while a saline injection was being given under the left breast.

Case 41.—Very long incision. There were multiple fibroids of the uterus; many were lying behind and below the peritoneum. Both ovaries were removed with the tumour. The stitches were all out by the ninth day and the wound was strapped. Five days later a coil of intestine lay under the dressing, rather firmly adherent to the edge of the wound which had burst open. The coil was separated and put back. The general peritoneal cavity was reopened. A small gauze drain was left in for five days. Afterwards recovery was uninterrupted.

---

[1] Part I. was published in The Lancet of July 8th, 1905, p. 69.

CASE 42.—A tumour of the left ovary of the size of a uterus at the sixth month; there had been hæmorrhage into the cavity of the cyst. Although the patient recovered well after the operation some months later she had general disseminated cancer of the peritoneum from which she died. The cyst had burrowed into the broad ligament to a moderate extent.

CASE 43.—The tumour contained 40 ounces of fluid; the pedicle was twisted and there was much blood inside the tumour, as well as papillary intracystic growths. The patient was three months pregnant at the time of the operation. A long incision was necessary owing to adhesions to the abdominal wall. The left ovary was healthy. The patient did not abort.

CASE 44.—The right tube, the seat of the pregnancy (tubal mole), formed a swelling of the size of a goose's egg. The patient was watched for seven days in hospital before operation. She was examined on the morning of March 5th, 1902, by the obstetric registrar. Soon after she had pain in the abdomen, vomiting, and rapid pulse. The operation was performed at 2.30 P.M. There were large clots in the peritoneum and much fresh free blood. The tube was adherent rather firmly in the pelvis and to the back of the uterus.

CASE 45.—The right multilocular ovarian cyst reached up to the umbilicus. The left ovarian cyst was of the size of a duck's egg. There was free fluid in the peritoneum.

CASE 46.—A fibroid reaching up to the umbilicus. On section it was found to be undergoing cystic change. There were lamellæ of yellowish material stretching across the cavities, suggesting fatty degeneration. The right ovarian cyst was of the size of a duck's egg; it contained pasty brown material. The left ovary was not removed.

CASE 47.—The uterine appendages (both sides) were removed with the uterus. On opening the uterus a submucous fibroid was found occupying its cavity that might have been removed by morcellement from below, but there were numerous other fibroids interstitial in situation. The whole mass was of the size of a pregnant uterus at three months.

CASE 48.—The tumour was a subperitoneal fibroid of the size of a fœtal head at full term, situated on the anterior surface of the uterus. The patient was five months pregnant at the time of the operation. The tumour was very moveable and was thought to be an ovarian dermoid. The patient did not miscarry.

CASE 49.—The left tube, the seat of the pregnancy (tubal mole), was removed. The appendages on the right side were left alone. The left upper extremity was paralysed for six weeks; ultimately the use of it was completely recovered.

CASE 50.—Chronic inflammation of the uterine appendages. Pelvic adhesions were present.

CASE 51.—Removal of the appendages. The left ovary was firmly adherent to the back of the broad ligament.

CASE 52.—A right ovarian cyst reaching above the navel; it had a very broad short pedicle. The left ovarian cyst was of the size of a hen's egg; it was very adherent in the pelvis. A part of the right tumour was very hard, with hard papillomata on the peritoneal surface and also inside the cyst.

CASE 53.—The left ovarian cyst (suppurating), of the size of a fœtal head at term, pressed down behind the uterus which was moderately enlarged by multiple fibroids. The left tube, dilated to the size of the ball of the thumb, was stretched over the ovarian cyst. This latter was very adherent in the pelvis but it was removed without rupture. It contained very fœtid pus. The right uterine appendages, matted together by chronic inflammation, were also removed. The patient had had a high temperature for several weeks before the operation.

CASE 54.—The patient was very fat. She had bronchitis and emphysema and could not lie down, also chronic Bright's disease. The lower abdominal parietes became œdematous and the sutures there suppurated with gaping of the wound. This condition extended upwards and finally the whole wound separated, so that its edges were eight inches or more apart. Through the interval the intestines were visible, thinly covered with lymph. The edges of the wound could not be kept together. The patient died on the twenty-seventh day after operation.

CASE 55.—Practically unilocular cyst of the left ovary; it contained 14½ pints of dark thin fluid which weighed 18½ pounds. The uterus showed several small subperitoneal fibroids. The right ovary was normal. The patient had a carotid aneurysm on the right side.

CASE 56.—A suppurating ovarian cyst on the right side reaching to the umbilicus had burrowed between layers of the broad ligament so as to be immoveable before enucleation. In removing the base of the cyst three inches of the right ureter were cleaned and exposed; this was seen to contract in vermicular manner on touching. The body of the uterus had to be removed to remove the tumour completely. The left ovary was also cystic and was removed. A gauze drain was left in for five days. The patient was said to have had ovariotomy done at a special hospital 15 years before.

CASE 57.—The patient was watched in hospital for nearly four weeks before operating (tubal mole). The left Fallopian tube was the seat of the pregnancy; the fimbriated end of the tube was open. The left ovary was cystic, it being of about the size of a hen's egg. The right ovary was also cystic and was larger than the left. The right Fallopian tube was normal. The pregnant tube was adherent to the omentum and sigmoid flexure.

CASE 58.—The tumour reached to the left ribs. A very large incision was necessary. The patient had repeated floodings before operation and was intensely anæmic. She was kept in bed for two weeks before the operation. Before the operation on examination the vaginal cervix could barely be reached. There were multiple fibroids and on opening the uterus one large submucous fibroid nearly free in the uterine cavity.

CASE 59.—A left ovarian cyst which reached half way from the umbilicus to the ensiform cartilage. The pedicle was twisted. Green fluid was present.

CASE 60.—A left ovarian cyst of the size of the uterus at term. It contained fluid that would hardly flow through the cannula. The right ovarian cyst was of the size of the uterus at three months. The patient had had amenorrhœa for ten weeks before the operation.

CASE 61.—The tumour reached the ribs on the left side. A month after the operation a loop of bowel passed through a hole in the omentum and became strangulated. Before the condition was recognised the patient became too bad to interfere. The cause was found on post-mortem examination. There were numerous adhesions between the small intestine and sigmoid flexure and the back of the tumour.

CASE 62.—Chiefly cervical fibroids undergoing cystic change and lying almost wholly behind the peritoneum. Four inches of the left ureter were dissected from the lowest part of the tumour. The mass weighed over 13 pounds. (For a full report of this case see the Transactions of the Medical Society, vol. xxvi., 1903, p. 235.)

CASE 63.—The operation was undertaken for a large fibroid of the right broad ligament blocking the pelvis. It was performed a few days before full term. Both mother and child did well. (For a full report of this case see THE LANCET of Jan. 17th, 1903, p. 157.)

CASE 64.—A large interstitial fibroid of the posterior uterine wall not involving the cervix. The right ovary was cystic and was removed with the tumour. The left ovary was not removed. The chief indications for operation were abdominal pain and menorrhagia.

CASE 65.—Double hydrosalpinx; both fimbriated extremities were closed. There were slight pelvic adhesions.

CASE 66.—Left multilocular ovarian cyst, containing 16 pints of greenish yellow fluid which weighed 12 pounds. The patient had had only ten years of married life and had been a widow for 25 years.

CASE 67.—A left pyosalpinx which was adherent to the rectum and the bladder; it burst as it was being separated. A right pyosalpinx was removed entire. The peritoneum was washed out with a saline solution. A gauze drain was left in for five days.

CASE 68.—Uterus enlarged to size at two to three months. Interstitial fibroid was suspected but was not found. The enlargement was simply due to general hypertrophy of the uterine tissue. The patient had suffered from menorrhagia for a long time and had been curetted twice before with only temporary benefit.

CASE 69.—A dermoid tumour of the right ovary which was of the size of the fœtal head at term. The pedicle was twisted. There were omental adhesions. A fibroid polypus attached to the body of the uterus had been removed a month before.

CASE 70.—A right ovarian cyst which extended up to the umbilicus. The pedicle was twisted.

CASE 71.—The tumour reached nearly to the umbilicus. The patient was very anæmic and had had menorrhagia for six years and also severe pain in the lower abdomen and left iliac region. There were parietal adhesions.

CASE 72.—A left ovary which was moderately cystic.

CASE 73.—The whole mass was of the size of the fœtal head at term. There were extensive adhesions in the pelvis and part of the tumour had to be enucleated out of the right broad ligament. The right Fallopian tube was much enlarged and thickened and communicated with the ovarian part of the cyst by an aperture admitting a probe easily.

CASE 74.—The left ovary and tube were removed. There were adhesions to the rectum, the broad ligament, and the back of the uterus. The uterus was adherent to the rectum. The right ovary was adherent to the back of the uterus and the broad ligament; it was freed from its adhesions but was not removed. The right Fallopian tube was normal.

CASE 75.—The right ovary was of the size of a hen's egg and was cystic. The left ovary was not identified. There were dense adhesions to the back of the uterus and in the pelvis. The patient died from peritonitis on the third day. Double pyosalpinx.

CASE 76.—Chronic inflammation of the uterine appendages with firm pelvic adhesions.

CASE 77.—The tumour reached the umbilicus and was somewhat hour-glass shaped. The upper part had undergone cystic change. The right ovary was enlarged and was removed with the tumour; the left was not removed.

CASE 78.—A right ovarian cyst of the size of a uterus at term. Before operation the temperature was 102° F. and the pulse was 112. The patient was taken ill suddenly three days before operation with severe abdominal pain and vomiting. At the operation the pedicle was found to be twisted three times. There was a good deal of free blood-stained fluid in the peritoneum but no peritonitis; the left ovary was cystic and was also removed.

CASE 79.—The uterus was enlarged to about the size of that at three months by carcinoma of the body. There was a fibroid (interstitial) in the anterior uterine wall near the fundus.

CASE 80.—Left ovarian cyst, mainly unilocular, of the size of an orange.

CASE 81.—The tumour occupied the greater part of the abdomen and the mass removed weighed 12½ pounds. There was a large interstitial fibroid of the posterior uterine wall which on section showed mucoid and cystic changes. The length of the uterine cavity in the mass removed was six and a half inches.

CASE 82.—A right ovarian cyst of the size of a child's head; the pedicle was twisted three times. The patient was some ten weeks pregnant at the time of operation and miscarried three days after it.

CASE 83.—Large prominent tumour in the lower abdomen, reaching to the umbilicus. There was no free blood on opening the abdomen; the uterus was close under the wound. The omentum was adherent over the mass behind and to the left of the uterus. The pregnancy was in the left Fallopian tube; it was removed. The fœtus was three inches long. The right Fallopian tube, being thickened and closed, was separated from a mass of adhesions and was also removed.

CASE 84.—Left ovarian cyst of the size of a large orange. The left Fallopian tube was slightly enlarged and closed externally. The right Fallopian tube was enlarged, closed, and adherent to the ovary; the mass so formed was firmly adherent in the pelvis.

CASE 85.—The right Fallopian tube was dilated to the size of a large potato in its outer portion and this was adherent to the intestine, omentum, and abdominal wall. Its pedicle consisted of two and a half inches of undilated Fallopian tube and was twisted several times on itself. The left Fallopian tube was of the size of an orange with only a few adhesions to it. Both dilated tubes were removed without interfering with the ovaries, which were healthy. The patient had two acute attacks of illness with symptoms of twisted pedicle. She was a virgin.

CASE 86.—The patient was doing quite well until the evening of the fourth day when, while an enema was being given, she suddenly became faint and collapsed and died in two hours. The cause must have been either syncope, which not rarely happens in old subjects when an enema is given, or pulmonary embolism.

CASE 87.—The tumour reached nearly to the umbilicus. The left ovary was of the size of a hen's egg, slightly cystic. On section it showed a well-marked large corpus luteum indistinguishable from that met with in pregnancy, though five years had elapsed since the last confinement and she had been a widow nearly five years. The fibroid was interstitial and showed on section mucoid and calcareous degeneration. The right ovary was damaged and bled rather freely and it was thought safer to remove it.

CASE 88.—The right ovary showed commencing cystic change.

CASE 89.—The operation was performed for obstruction due to the presence of a large interstitial cervical fibroid which in the later months prevented the cervix being reached per vaginam on examination. Both mother and child did well. (For a full report of this case see THE LANCET of Jan. 17th, 1903, p. 157).

CASE 90.—Both Fallopian tubes were dilated to the size of the ball of the thumb and adherent to corresponding ovaries. Masses so formed were firmly adherent in the pelvis, especially to the rectum, from which they were separated with difficulty. Some pus escaped on separating the adhesions. A gauze drain was used.

CASE 91.—This was an emergency operation. The patient was admitted with all the symptoms of severe internal hæmorrhage. The pulse was 130, irregular, and feeble. Her face was very pale and she was so bad that intravenous injection of salt solution (four pints) was done while the operation was in progress. A large amount of fresh blood and clot was found in the peritoneal cavity. The pregnancy was in the right Fallopian tube which was removed in the usual way.

CASE 92.—Both ovaries and tubes were removed with the uterus. The right ovary formed a tumour of the size of a goose's egg which on subsequent examination was found to be carcinomatous.

CASE 93.—The patient was laid up with fever and abdominal pain some weeks before operation. There was swelling in the lower abdomen reaching half-way to the umbilicus. On opening the abdomen the surface in view over the swelling consisted of coils of intestine and omentum roofing the underlying swelling. On separating several coils of intestine pus came up from the region of the left tube and what was believed to be the left tube was separated from the left side of the pelvis and removed. The same was done on the right side. A gauze drain was used. The operation was extremely difficult.

CASE 94.—The left Fallopian tube was dilated and tortuous; it was adherent to the rectum and left ovary. The adhesions were separated and the tube was removed. It contained a tubal mole. The left ovary was not removed.

CASE 95.—The freely moveable lump in the abdomen of the size of a child's head was a tumour of the left ovary. The swelling felt in the left side of the pelvis on vaginal examination was a tumour of the right ovary. Both tumours were removed without puncturing. There was some clear free fluid in the abdominal cavity. This patient did quite well as regards this operation but some months later she died with a malignant growth in the region of the liver.

CASE 96.—A left ovarian cyst reaching to the umbilicus; it was densely adherent in the pelvis and to the intestine. The right ovarian cyst was of the size of a duck's egg. Numerous small subperitoneal fibroids were seen on the uterus.

CASE 97.—The tumour reached to the umbilicus. Marked anæmia was present. The right ovary was slightly but definitely cystic; both it and the left ovary were removed with the tumour. The peritoneal surface of the uterus was studded with curious granular elevations varying in size from that of a millet seed to a quarter of an inch in diameter. The appea
toneum is affected by
however, elsewhere.
fibroids in its cavity of
fibroids varying in size.

CASE 98.—Both Fallopian tubes were dilated to the size of the thumb and were firmly adherent in the pelvis, also to the omentum, intestine, uterus, and vermiform appendix. The last was adherent at the bottom of Douglas's pouch. There was no pus in the tubes. There were several fibroids in the uterus. The patient was very anæmic and had been losing blood daily for some time before operation.

CASE 99.—A right multilocular ovarian cyst of the size of a uterus at term. It contained clear gummy fluid, coagulating at once on exposure to air. The fluid would not flow through the cannula. The left ovary was healthy.

CASE 100.—An emergency operation for ruptured extra-uterine gestation. The abdomen was full of blood and clots. The pregnancy was in the left Fallopian tube. The ovum had escaped into the peritoneum and was not identified among the clots. An unusual point was the firm adhesion of the pregnant tube to the sigmoid flexure, and the broad ligament could not be transfixed and tied till this was separated. The left ovary contained a well-marked corpus luteum. Intravenous injections of salt solution and brandy were made during the operation.

CASE 101.—Both tubes were dilated and were adherent to the ovaries. The masses so formed were firmly adherent in the pelvis. The right ovary formed a cyst of the size of a Tangerine orange. The pedicle was friable near the uterus on the right side and the ligature cut through there. A ligature was passed with a sharp needle through the uterine tissue and this controlled the bleeding. A gauze drain was employed on account of the oozing. Laparotomy had been done previously by someone else but nothing had been removed.

CASE 102.—There was chronic inflammation of the right uterine appendages. There were slight adhesions.

CASE 103.—Chronic inflammation of the left uterine appendages was present. There were slight adhesions.

CASE 104.—Both tubes were considerably dilated and were firmly adherent to the ovaries and in the pelvis. Removal without bursting was effected. There was no pus but some turbid greyish-white fluid.

tion. A gauze drain was passed into the raw surface left after enucleating. This cyst contained extensive soft papillary growths in its interior.

CASE 106.—The tumour reached nearly to the umbilicus and had caused retention of urine. On opening the abdomen the surface of the tumour presented no irregularity except where there was a small subperitoneal fibroid of the size of a pea. The colour and general aspect were extremely like that of the pregnant uterus. Great difficulty was found in getting the tumour out of the wound. This was only possible after cutting and tying the upper parts of the broad ligaments and with the aid of an assistant pushing up the tumour from the vagina. Afterwards it was found that there was a large soft interstitial fibroid of the anterior uterine wall extending also into the supravaginal cervix.

CASE 107.—An emergency operation; supposed to be a case of ruptured extra-uterine. The patient was extremely collapsed and almost pulseless. Amenorrhœa had lasted for two months. On opening the abdomen it was found to be a case of intestinal obstruction due to a band, which was divided. The uterus was evidently two months pregnant and there was a small simple ovarian tumour of the size of an orange on the right side. This was removed. The patient died about eight hours later. The bowels acted six times between the time of the operation and the patient's death.

CASE 108.—On opening the abdomen a swelling was found reaching a hand's breadth above the pubes. It was roofed over by adherent omentum, sigmoid flexure, bladder, cæcum, and vermiform appendix. On separating these a cavity was opened up containing a mass of clot six inches long and three inches thick, below and behind the uterus. The left Fallopian tube was the seat of the pregnancy and it was removed.

CASE 109.—The ovaries were definitely enlarged, so they were removed with the uterus which contained three interstitial fibroids.

CASE 110.—There was chronic inflammation of the uterine appendages.

CASE 111.—Chronic inflammation of the uterine appendages was present and there were dense pelvic adhesions, especially to the rectum.

CASE 112.—The right tube was the seat of the pregnancy; its outer end was widely dilated and had evidently allowed the mole found in the pelvis to be extruded. The right appendages were removed. The left tube was closed and dilated and so it was also removed. The mole was of the size of a Tangerine orange. An emergency operation.

CASE 113.—Both sets of uterine appendages were removed with the uterus.

CASE 114.—An ovarian cyst containing 108 ounces of thin black fluid. There were dense adhesions between the lower back part of the tumour and the back of the right broad ligament and the back of the uterus. A thin layer of uterine tissue had to be removed to get away the cyst completely. Several ligatures had to be passed through the uterine tissue with a sharp needle in a handle.

CASE 115. A left multilocular ovarian cyst of the size of an ordinary potato was lying in front of the uterus. The right ovary was definitely enlarged by cystic changes but was smaller than the left.

CASE 116.—A right ovarian cyst of the size of a child's head with a twisted pedicle. There were a little free fluid in the abdomen and a great deal of fresh blood in the cavity of the tumour and in the tissues beyond the twist.

CASE 117.—The operation was performed one week before full term. The right Fallopian tube was not dilated but was found to be closed externally. A loop of the left Fallopian tube was removed.

CASE 118.—The tumour reached up to the umbilicus; it had been previously diagnosed as fibroid. There was some fever before operation. Extensive enucleation from between the layers of the left broad ligament was required.

CASE 119.—The tumour reached up to the umbilicus. A tubo-ovarian cyst on each side required enucleation at the lowest part on each side. The gap left was stitched together.

CASE 120.—A lump was felt of the size of a cocoa-nut. It was thought to be a suppurating ovarian. There were high temperature and pain. At the operation found to be due to a mass of omentum and intestine adherent. On separating the adhesions fœtid pus escaped. There was a small hole in the bowel which was made while separating the adhesions. It was stitched up. No cause for the abscess was discovered. The appendix was healthy.

CASE 121.—Both Fallopian tubes were closed; they were not much dilated. There were adhesions to the vermiform appendix and the sigmoid flexure.

CASE 122.

The right ovary was not removed.

CASE 124. A right
burrowed between the
the uterus internally a
was widely adherent to the bladder and roofed in the tumour. The tumour required extensive enucleation and the ligature of many vessels. The left Fallopian tube was dilated to the size of a thumb and was adherent to its ovary which was also removed. The gap in the right broad ligament was closed with fine silk.

CASE 125.—There was chronic inflammation of the left uterine appendages. The Fallopian tube was dilated and closed. The left ovary formed a cyst of the size of a duck's egg; it was closely adherent to the sigmoid flexure and required scissors to separate it. The right ovary and tube were normal.

CASE 126.—A tumour of the size of
was menorrhagia. The cervix was dilat
was found which could not be removed
ectomy was performed. Both ovaries, which were of the size of a hen's egg, were also removed.

CASE 127.—The patient had had the uterine appendages removed for fibroids some years before. There were coils of intestine adherent closely under the old scar which had to be separated with great care before the general peritoneal cavity was reached. The bowel was damaged over an area of the size of a sixpence. Four Lembert sutures were required. The tumour was
to the floor and sides of the pelv
into the tumour about the level of
experienced in catching the left ut
tumour being in the way. The tun
dense adhesions. The left ureter was seen during dissection. A gauze drain was passed through into the vagina.

CASE 128.—The tumour reached to the umbilicus. There were multiple fibroids. One ovary was left. The mass weighed six pounds.

CASE 129.—A fibroid of the right ovary of the size of a child's head.

There was no free fluid in the peritoneum. The tumour was calcified on its surface in various places. There were no adhesions. The left ovary was healthy.

CASE 130.—The operation was performed for menorrhagia. The left ovary was cystic and of the size of an egg and was removed with the tumour. The right ovary was not removed.

CASE 131.—A left ovarian cyst of the size of a uterus at seven months. The pedicle was twisted. There were slight adhesions; the pedicle was thick and œdematous; it was tied in sections. The right Fallopian tube was dilated to the size of the thumb and was adherent in the pelvis. The right ovary formed a cyst of the size of a hen's egg.

CASE 132.—A small ovarian cyst of the size of a hen's egg, which caused menorrhagia.

CASE 133.—A left ovarian cyst of the size of an orange; it was adherent to the rectum and elsewhere in the pelvis. The right ovary was decidedly enlarged so it was removed as well.

CASE 134.—The left Fallopian tube was dilated to the size of a cocoanut and contained a tubal mole. It was removed. There were many recent adhesions.

CASE 135.—A left ovarian cyst of the size of a uterus at term. It had grown between the layers of the broad ligament and raised the peritoneum from the left iliac fossa, so that the peritoneal surface of the tumour was continuous with that of the abdominal wall some two to three inches to the left of the incision. It was enucleated. Several inches of the left ureter had to be dissected from the base of the cyst. It contained half a bucketful of thin brown fluid. There were papillary growths on the inner surface of the cyst. There were a right ovarian cyst of the size of a duck's egg and a right hydrosalpinx.

CASE 136.—A tumour of the size of a uterus at four months. The right ovary was not removed.

CASE 137.—A left ovarian cyst of the size of a small cocoanut. The left Fallopian tube was dilated. The mass was fixed everywhere in the pelvis and above to the bladder and omentum. The right Fallopian tube was dilated to the size of the thumb and was adherent to the ovary; this was also removed.

CASE 138.—A left ovarian cyst containing nine pints of straw-coloured fluid. There was a right ovarian cyst of the size of a duck's egg.

CASE 139.—Both sets of uterine appendages were removed with the uterus. The lower angle of the wound broke down about two weeks after operation and a sinus formed from which in a few days large quantities of pure bile passed daily. This gradually diminished and the wound finally closed completely.

CASE 140.—A right ovarian cyst of the size of a child's head and containing straw-coloured fluid. There was a left dermoid ovarian cyst.

CASE 141.—A degenerating subperitoneal fibroid of the size of a uterus at term. It was supposed to be an ovarian cyst. The uterus was not lengthened. The tumour was found on section to be undergoing extensive cystic change and contained much jelly-like material. The right ovary was not removed. Omental adhesions were present.

CASE 142.—A large fibroid in the anterior uterine wall which caused a curious twisting of the uterus on its axis and partly beneath the peritoneum, so that the tumour could not be brought out of the wound till the peritoneum had been stripped down. The left ovary was not removed.

CASE 143.—The right ovary was not removed. On section of the fibroid it was found to contain a cavity admitting two fingers lined by smooth membrane.

CASE 144. The patient had had anterior and posterior colporrhaphy and amputation of the vaginal cervix for prolapse two years previously. The right ovary was not removed. The uterus was of the size of a large cocoanut; it weighed two pounds.

CASE 145.—A left ovarian cyst reaching to the umbilicus and a right ovarian cyst of the size of an orange. Both pedicles were twisted. The tumours were adherent in the pelvis, also to the omentum and bladder. Both cysts contained dark thick fluid. The patient had had an early miscarriage, the ovum being of the size of a walnut, on June 12th, 1905.

CASE 146.—A suppurating right ovarian cyst of the size of a large orange. The right Fallopian tube was thickened, enlarged to the size of a thumb, and was adherent to the tumour. There were extensive pelvic adhesions. The cyst burst during removal. The patient had undergone ovariotomy for left ovarian cyst some time before.

CASE 147.—The tumour occupied the greater part of the abdomen. There were multiple fibroids; one posteriorly and one anteriorly had grown under the peritoneum and could not be brought up till the peritoneum was incised. Both ovaries were removed owing to their position.

CASE 148.—The tumour was of the size of a uterus at five months. The right ovary was not removed. There were a good many rather recent adhesions and in the region of the left tube several loculi formed by serous perimetritis. The left Fallopian tube was dilated and the left ovary was twice the normal size.

CASE 149.—The intestines and omentum were matted so as to form a roof to the pelvic cavity. On separating these the right Fallopian tube was found to be dilated, containing dark firm blood clot, presumably a tubal mole. The case was supposed to be chronic salpingo-oöphoritis before operation.

CASE 150.—A right multilocular ovarian cyst of the size of a uterus at seven months; it contained thick black fluid and was extensively adherent in Douglas's pouch. The pedicle was twisted. The uterus was enlarged to the size of a four months gestation by multiple fibroids. The left ovary was three times the normal size and was also removed. On section it showed a well-marked corpus luteum like that of pregnancy.

(To be continued.)

GLOUCESTERSHIRE COMBINED SANITARY DISTRICT.—At the meeting of the Cirencester rural district council held on July 17th a resolution was read from the Gloucestershire sanitary authorities protesting against the action of the Chipping Sodbury rural district council in withdrawing from the combination without communicating with the other authorities.

TUBERCULOUS DISEASE OF THE CÆCUM, WITH NOTES ON A CASE.

BY R. ATKINSON STONEY, M.B. DUB.,
VISITING SURGEON TO THE ROYAL CITY OF DUBLIN HOSPITAL; LECTURER IN SYSTEMATIC SURGERY, ROYAL MEDICAL SERVICES SCHOOL; AND DEMONSTRATOR OF ANATOMY, SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN.

TUBERCULOUS disease of the cæcum must be a comparatively common occurrence, as Fenwick and Dodwell after examining a large number of cases of tuberculosis found that the cæcum was involved in 85 per cent. of all cases of intestinal tuberculosis. The infection of the cæcum may be either primary or secondary, the latter being most common in children and young adults, the former between the ages of 25 and 40 years. There are two main types, the ulcerative and the hyperplastic. If it occurs during the active progress of pulmonary disease it usually pursues an ulcerative or destructive course with varying rapidity, but if secondary to a healed pulmonary lesion, or if it is primary, then the infection is of a mild type and the pathological changes are of a chronic hyperplastic character. It is of these latter cases that I wish to speak and of which I recently had one under my care in the Royal City of Dublin Hospital.

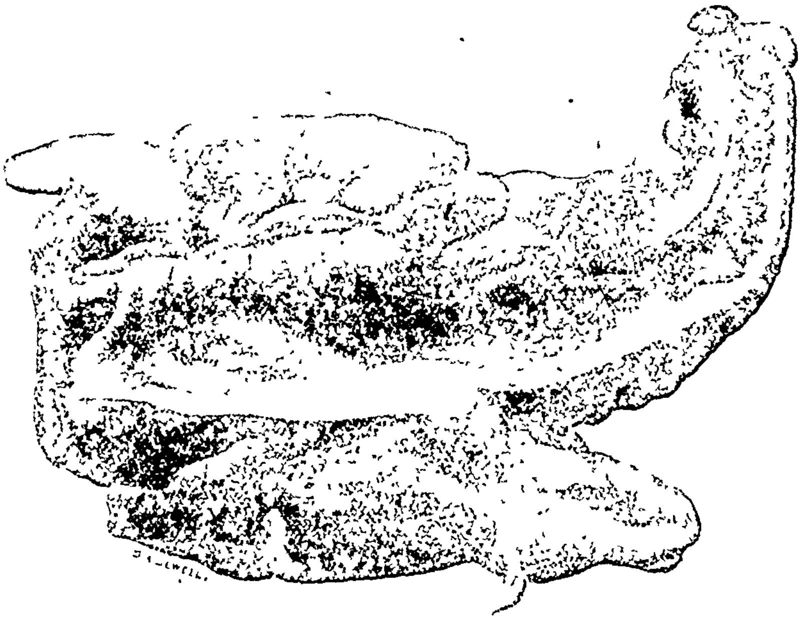
The best account of this disease and of the literature on the subject that I can find is Crowder's article in the *American Journal of the Medical Sciences.* According to him the chronic hyperplastic form of tuberculosis of the cæcum, giving rise to great thickening of the walls and narrowing of the lumen of this part of the intestine, was first described by Durante in 1890. In 1891 Billroth demonstrated a resected cæcum which presented itself clinically as a large hard swelling in the right iliac region, in every respect resembling a carcinoma. Hartman and Pilliet in the same year in Paris called attention to a form of tuberculous typhlitis which accurately resembles a carcinoma and which is not to be distinguished from it by the naked eye. In 1892 Sachs collected 12 cases from the literature and added one of his own. There was no caseation of the retrocæcal glands or ulceration of the mucosa, and the lumen was almost obliterated. Conrath collected 84 cases which had been surgically treated with the low mortality of 16·7 per cent. Crowder himself reported two cases, in the second of which there were combined malignant disease and tuberculosis, there being a perforating tuberculosis of the cæcum which had been secondarily invaded by carcinoma. The mucosa is usually ulcerated but may be merely thickened and covered with papillomatous masses of varying size. The wall of the bowel is thickened, firm and irregular, the lumen being either dilated or contracted; the enlargement and thickening of the cæcum are due to a hyperplasia and not to a compensatory hypertrophy; it is inelastic and rigid from tuberculous infiltration. The tendency is usually for the disease to spread along the colon and not into the ileum, but in cases mentioned by both Esmarch and Sachs there was a similar tuberculous tumour formation in the lower part of the ileum. The retrocæcal glands are practically always involved and later the mesenteric glands also. The appendix is not usually involved to any great extent, but in a case of Thierry and Routier it had undergone changes similar to those of the cæcum.

The characteristic clinical feature of these cases is the development of a tumour which is hard and nodular, moveable but usually only towards the middle line, not in an outward direction, not moving with respiration, and giving a hollow, impaired tympanitic note on percussion. The patients are frequently well nourished but there is usually some disturbance of digestion, attacks of colicky pain occurring at irregular intervals without any apparent cause. "Carcinoma of the cæcum presents symptoms so identical in nature that it is impossible to differentiate the two and even after removal the specimen has often been regarded as malignant until subjected to microscopical examination."

On March 20th last I was asked by my colleague, Dr. T. G. Moorhead, to see a patient of his suffering from a tumour in the right iliac fossa. The following is an account of the case. The patient, a female, aged 23 years, was admitted to the Royal City of Dublin Hospital on March 11th complaining of swelling of the left leg, pain in the left hip, pains in the stomach, palpitation of the heart on exertion, giddiness, headache, and general weakness. One sister died from consumption; several brothers and sisters were also dead but the cause of death was unknown. The patient had been more or less delicate since birth; for the past three years she had been getting worse and she had been confined to her bed, only getting up for an hour or two daily, for some time prior to admission to another Dublin hospital last January. Her chief complaint then was the pain in the left hip; this pain was most marked at night and travelled down the back of the leg to the ankle. She obtained no relief during a month's stay in hospital. For a month before her admission to the Royal City of Dublin Hospital she had been troubled with her stomach; she vomited a few times after taking food and had pain of a stabbing character shooting up from the right side, across the abdomen, and through to the back; it was increased by eating, relieved by pressure, and came on immediately after taking food. She stated that she had always been subject to constipation.

On examination the patient was very anæmic. Her teeth were very carious. The thorax was normal. The left hip was normal; there were no impairment of movement, no pain on movement or pressure, and no deformity. Great pain and tenderness were present on pressure over the spines of the first and second lumbar vertebræ. There was marked but not absolute rigidity of the lumbar spine; pain in this region was caused by downward pressure on the shoulders or vertex. There was no abnormal prominence or angular curvature. The abdomen on inspection appeared to be normal; on palpation very marked hyperæsthesia was present, mapping out in a very beautiful manner the eleventh dorsal segment of Head on the right side. Some pain was present on deep pressure over the right iliac fossa. In this region a large, somewhat irregular tumour could be felt; this was freely moveable in a lateral direction but not in a vertical and was dull on percussion. There was no history suggesting previous attacks of appendicitis or of the passage of blood or pus per rectum. Vaginal and rectal examination revealed nothing further except that the tumour did not appear to be connected with any of the pelvic organs. Owing to the great hyperæsthesia there was considerable difficulty in examining the tumour, so the patient was examined under an anæsthetic on March 23rd. The tumour was then found to be irregular, of about the size of an orange, in the position of the cæcum, freely moveable in a horizontal direction, especially towards the middle line, but only to a slight extent in a vertical direction; it did not move with respiration. The right kidney could be palpated above the tumour. Examination of the urine for tubercle bacilli gave negative results. The temperature was subnormal since admission. The pulse was variable and usually over 90; the respirations also were variable and frequently over 30 per minute.

On March 25th the abdomen was opened by an oblique incision over the right iliac region. The great omentum was found to be adherent to the bottom of the right iliac fossa. The adhesions were easily broken down. A band of thickening was found surrounding the ileum at a distance of about one and a half inches from the cæcum, somewhat rough on the surface and with all the appearance of a typical malignant stricture. The cæcum was then exposed and found to be greatly enlarged and very hard; the appendix also was swollen and hard, especially at its base. These appearances are well seen in the accompanying illustration. As the tumour was thought to be malignant the portion of the omentum which had been found adherent to the iliac fossa was removed. The ileum was divided about one and a half inches on the proximal side of the thickening, the proximal end of the gut being closed by a continuous through-and-through silk suture which was then invaginated and buried by a continuous serous silk suture. The distal end was ligatured, the mucous membrane being swabbed with pure carbolic acid, and wrapped in a piece of gauze. The end of the mesentery was then ligatured in sections and divided, the peritoneum on the outer side of the cæcum and ascending colon was divided, and the whole mass was lifted off the posterior abdominal wall and the colon divided between two clamps. A lateral anastomosis was then made between the ileum and the transverse colon by means of a double row of continuous silk sutures. An attempt was then made to close the cut end of the colon in the same manner as the ileum, but as the peritoneal covering was scanty the serous stitch could not be completed and it was thought safer to fix the gut in the upper angle of the wound which was closed by silkworm gut sutures with the exception of the upper inch. The operation lasted for one and three-quarter hours and was well borne by the patient.



Tuberculous ileum, cæcum, and appendix. The thickened band surrounding the ileum and the corresponding stricture are well shown, also the great thickening of the walls of the cæcum and the stricture in the commencement of the ascending colon, observe also the peculiar shape and appearance of the appendix.

For the first few days after the operation some uneasiness was caused by the fact that the patient's respirations and pulse were abnormally rapid, the former varying from 36 to 50 and the latter from 128 to 148 per minute; but the patient slept well and there was no abdominal tenderness or rigidity. The temperature on the night after the operation rose to 101° F., the next night it was 100°, and the following night 99°; after that it did not rise above normal during her stay in hospital. There was occasional vomiting of small quantities of fluid for the first two days after the operation. The patient was given nutrient enemata every four hours. On the second day she was allowed one drachm of panopeptone every hour and was given a simple enema in the evening which had a fairly good result. The next day the patient was given a soap-and-water enema which produced a good motion and on the following day the bowels acted naturally. From this on the patient made an interrupted recovery; the wound healed by first intention except in the upper part, where a small fæcal fistula formed on the sixth day but closed within a fortnight. The nutrient enemata were stopped on the eighth day after the operation, the patient was allowed bread on the thirteenth and meat on the sixteenth day, she was allowed up on the twenty-first, and left hospital on the thirty-fifth day after the operation. At the time of her discharge the bowels were moving regularly every day without the assistance of any medicine and she had put on weight;

the symptoms present in the lumbar region before operation had entirely disappeared.

On opening the intestine after removal it was found that where the ileum was surrounded by the thickened band there was a distinct stricture reducing the lumen of the bowel to a diameter of half an inch: there was, however, no sign of ulceration or presence of tubercles either in the mucosa or on the peritoneum; from this to the cæcum the wall of the gut was slightly thickened. The walls of the cæcum were enormously thickened, the lumen being merely represented by a small channel. The ileo-cæcal valve had entirely disappeared and the opening of the appendix was reduced to a minute hole. At the commencement of the ascending colon about one inch from where the small and large intestine joined there was a second stricture, the lumen being reduced to about one-third of an inch in diameter. The appendix was about one inch in length, conical in shape, and solid. Most of these points can be well seen in the accompanying illustration. Portions were removed from both strictures and one of three or four slightly enlarged glands found in the loose tissue behind the cæcum. These were cut and examined microscopically; they presented the typical appearances of tuberculosis—giant cells, tubercles, and small patches of caseation. Before the microscopical examination the tumour was thought by all who saw it to be a scirrhous carcinoma and even afterwards on examining the tumour again nothing could be seen by the naked eye to suggest the fact that it was of a tuberculous origin.

THE RAPID ESTIMATION OF THE AMOUNT OF SUGAR IN URINE.

By R. T. WILLIAMSON, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, MANCHESTER, ETC.

FOR most clinical work the fermentation method is quite satisfactory for the estimation of the amount of sugar in diabetic urine, providing certain precautions be taken. But it is necessary to wait for 24 hours before the results can be obtained. Sometimes, however, it is desirable to obtain the results of the quantitative estimation of sugar in a few hours or immediately. In such cases the ordinary method of estimation with Fehling's solution is trustworthy but it is troublesome on account of the considerable amount of time required, especially if many specimens of urine have to be examined. Hence many simpler modifications have been employed. Recently I have devised a slight modification in the performance of Gerrard's method which I have found so useful and rapid that for ordinary clinical work I prefer it to all other methods I have tried. The estimation can be made in a few minutes, only a very small amount of urine is required, and the results are sufficiently accurate for most clinical work. The only apparatus required are a test-tube of ordinary size (diameter about five-eighths of an inch); a small narrow burette tube (diameter about three-eighths of an inch and graduated to indicate one-tenth of a cubic centimetre); and a spirit lamp. At my request Messrs. Burroughs, Wellcome, and Co. have kindly prepared "soloids," each equivalent to one cubic centimetre of Fehling's solution, decolourised whilst boiling with a 5 per cent. solution of potassium cyanide (Gerrard's solution).

The rapidity of the method is due to the use of these soloids and to the performance of the estimation with small quantities of the fluids. The estimation is made in the following manner: A little water is placed in the test-tube (about half a drachm or a little more). In it are dissolved, by heating with a spirit lamp, one of the copper sulphate soloids and then one of the alkaline tartrate soloids which are supplied by Messrs. Burroughs, Wellcome, and Co.; together these two soloids form a solution equivalent to one cubic centimetre of Fehling's solution. (The copper in this solution requires 0·005 gramme of sugar for its complete reduction.) Then one of the potassium copper cyanide soloids (already mentioned) is dissolved by heat in the same fluid. The urine which has been placed in the burette tube is rapidly dropped into the boiling fluid in the test-tube until the blue colour of the solution disappears. The amount of urine used is read off from the graduated burette. This quantity must therefore contain 0·005 gramme of sugar. The percentage of sugar can then be easily calculated. When the amount of sugar present is small the urine may be employed undiluted; when the urine contains much sugar or when greater accuracy is desirable it is best to dilute the urine (1 in 10).

The following are the advantages of this simplified method. 1. The estimation can be made very rapidly; only a few minutes are required. (As in the ordinary method of performing Gerrard's test, the oxide of copper is dissolved by the potassium copper cyanide as soon as it is reduced from the Fehling's solution by the saccharine urine and hence the troublesome waiting for the copper oxide precipitate to subside is avoided.) 2. The method can be employed when only a very small amount of urine is available. 3. The estimation can be made easily when the urine only contains a very small amount of sugar. These specimens are very troublesome when the ordinary method of estimation with Fehling's solution is employed.

The use of the soloids saves the time required for accurately measuring the test reagents. The soloids are dissolved whilst the fluid is being heated. The performance of the test with small quantities of the fluids diminishes the time required for boiling the solution; the use of the narrow burette tube increases the accuracy of the measurement of the amount of urine required in the test and thus compensates to some extent for the loss of delicacy through the use of small quantities of fluids. When greater accuracy is desired, one of the cyanide soloids may be dissolved in water in a second test-tube and this solution may be used as a standard of the exact tint to which the mixed Fehling's solution and double cyanide (in the first tube) should be reduced by the addition of the diabetic urine.

Although there are many other rapid methods of sugar estimation, I have ventured to record the modification just described since I have found it so useful in medical practice.

Manchester.

A CASE OF PULMONARY EMBOLUS WITH SOME PECULIAR FEATURES, OCCURRING SHORTLY AFTER NORMAL LABOUR.

By R. J. WAUGH, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER, BETHNAL GREEN INFIRMARY.

A WOMAN, aged 25 years, a healthy multipara, pregnant at full term, was admitted to the Bethnal Green Infirmary on Nov. 16th, 1904. The second stage of labour was well advanced at 11 P.M. on the 17th when I was called to see her. On my arrival I found the fœtal head already distending the vulva and a few moments later the child, a full-time, healthy, male infant weighing 8 pounds, was born. I expressed the placenta almost immediately and left the patient quite comfortable at 11.25 P.M., 15 minutes after the completion of the third stage. At 12.30 A.M., an hour later, I received an urgent message asking me to come at once to see the patient as she appeared to be dying. On reaching the ward I found her sitting propped up in bed gasping for breath. Dyspnœa was extreme, the features were pinched, the lips were blue, and the face and hair were bathed in a clammy sweat. The pulse was rapid, compressible, and extremely irregular. On examining the chest I found the cardiac dulness to be extended as much as an inch beyond the right sternal margin: otherwise irregular and tumultuous action was the only abnormal feature. On auscultation of the upper lobe of the left lung no breath sounds were audible but in their place many fine moist râles could be heard, giving one the impression of an intense local œdema. The percussion note over the corresponding area was distinctly impaired. The lower lobe of the left lung seemed to be but little affected, though the breathing was somewhat faint in this region, especially when compared with the right side of the chest, where the breath sounds might be described as almost puerile in character, so much were they increased. From the commencement of the attack (which I was informed occurred quite suddenly, the patient complaining of great pain above the right breast and difficulty in breathing) a colourless frothy liquid, at times slightly stained with hæmoglobin, had been coughed up in considerable quantities. There was about half a pint in all. Of specific gravity about 1030, it coagulated on boiling, contained no red corpuscles when examined microscopically, but gave the spectroscopic test for oxyhæmoglobin. As the more alarming symptoms seemed to be due to an acute engorgement of the right ventricle a small venesection was performed, about ten ounces of blood being withdrawn, and five minims of solution of strychnine, together with 20 minims of ether purus, were given hypodermically, weak brandy and water being ordered by the mouth, in teaspoonful doses, as the respiratory distress rendered swallowing very difficult.

The patient's condition having undergone a slight improvement I left her about 4 A.M., giving instructions that the hypodermic injections should be continued as directed and that I should be sent for immediately if any change for the worse took place. To my surprise I heard no more of the patient until I made my usual visit to the ward on the following morning at 10 o'clock. She was then resting quietly; all signs of dyspnœa had disappeared and, except for some facial pallor and slight exhaustion, she seemed to be none the worse for her experience of the early hours. On examination of the chest a few moist râles could still be heard over the affected area while all signs of cardiac dilatation had vanished and at 4 o'clock on the same afternoon the chest, being again examined, this time in company with one of my colleagues, was pronounced by him to be normal. From this time onwards the puerperium was uneventful, save for the development of a small, superficial mammary abscess which rapidly yielded to appropriate treatment, and the patient was allowed up on the twenty-first day and discharged herself from the infirmary two days later.

As regards a diagnosis, dyspnœa coming on suddenly after labour in a healthy woman such as this patient, taken together with the physical signs present during the attack, seemed to me to point to an embolus of uterine origin which had been carried away and become arrested in the pulmonary circulation, while the fact of the signs clearing up so rapidly (all physical signs had disappeared 16 hours after onset) makes it probable that the embolus, if such it were, must have been composed of air rather than dislodged blood clot. If, however, this diagnosis be admitted as possibly a correct one it seems difficult to imagine how the air was introduced into the uterus, since no intra-uterine manipulations were made nor was a douche given either before or after labour. The point about which I feel most interest is as to whether a hurried expulsion of the afterbirth, such as was effected in this case, could have given rise to the condition described, air presumably being sucked into the vagina as the uterus was released from the somewhat powerful grasp necessary to expel a not sufficiently separated placenta; and if this be so, why so lengthy an interval as an hour elapsed before the onset of the disquieting symptoms? Should any of your readers feel sufficiently interested I should be grateful for an expression of opinion upon this, to me, somewhat puzzling experience.

Cambridge Heath, N.E.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF FORWARD DISLOCATION OF THE RADIUS AND ULNA WITHOUT FRACTURE OF THE OLECRANON PROCESS OF THE ULNA.

By F. W. STAUNTON, M.B. DUB.,
HONORARY SURGEON TO WATERFORD COUNTY AND CITY INFIRMARY.

THE patient in this case was a man, aged 45 years, whose description of his accident was to the effect that "while walking quickly downstairs he felt as if he had trod on something slippery; his foot went from under him, he twisted round in order to save himself and fell backwards downstairs, the tip of his left elbow striking the edge of the staircase first." On examination the elbow was seen to be held at an angle of 130°. It could be slightly flexed and extended and permitted a good deal of lateral movement. The head of the radius and the olecranon process of the ulna could be felt lying on the shaft of the humerus about two and a quarter inches above the condyles. It was possible to feel both condyles of the humerus, the olecranon fossa, the coronoid depression, the trochlea, and the capitellum; in fact, the lower end of the humerus could be easily grasped in the hand. There was distinct lengthening of the forearm.

The points of interest in this case were: (1) its rarity; (2) the absence of fracture of the olecranon; and (3) the maintenance of the relationship between the radius and ulna. Attention has been called to this in Treves's "Surgery" by Mr. Marmaduke Sheild who states that "this dislocation is extremely rare," and quotes Canton's case in which the radius maintained its relationship to the ulna. Looking up the literature on the subject I find that there are about 12 recorded cases. Erichsen states that six cases of this dislocation are on record. Rose and Carless state that fracture of the olecranon always occurs in this dislocation. Gould and Warren in their "International Text-book of Surgery" refer to this dislocation as "rare and its occurrence without existing fracture has been doubted; in point of fact the latter complication has been still more rarely recorded." Helferich says: "This is a very rare injury; it was formerly said it never occurred without simultaneous fracture of olecranon. May be produced by a fall or blow on olecranon while arm is in extreme flexion." Hamilton quotes nine cases and states "that it seems to have been in most cases caused by a fall upon elbow while forearm is forcibly flexed." Cheyne and Burghard state that this dislocation "is sometimes met with ...... as result of a severe blow upon back of flexed elbow."

Stimson in his book refers to a case which was under his care in 1895. He says: "The elbow is held at a right angle but can be somewhat flexed and extended; is moveable laterally. The epitrochlea can be plainly felt, also the inner face and edge of trochlea. The overlying flexor muscles of hand having been torn away from humerus, the tip of olecranon is below, and even a little in front of, the trochlea, the inner anterior portion of articular surface of which can also be felt on depressing the skin. The head of radius in front of capitellum; the forearm is markedly abducted. ...... The only other reported case is Wright's. The symptoms were similar."

Waterford.

DISAPPEARANCE OF RODENT ULCER UNDER THE APPLICATION OF THE X RAYS.

BY FREDERICK B. JEFFERISS, F.R.C.S. EDIN.,
M.R.C.S. ENG., L.R.C.P. LOND.

THE successful treatment of rodent ulcer by the application of the x rays is now well established and many cases are on record where a complete recovery has resulted. The same, however, cannot be said of carcinomata, some cases improving for a time but relapsing again or even getting worse as the treatment is continued.

The patient in the present instance was an elderly woman who suffered from an epithelial growth on the left frontal region. The history was to the effect that about two years before she first came under my notice she observed a small pimple at the site of the growth which she injured by accidently striking it against the mantelpiece causing ulceration. She treated it herself with zinc ointment without any benefit and it steadily grew for the two years. When I first saw her the growth was about as big as a five-shilling piece, rounded in shape, and very much raised, the ulcer on the top of the growth being about half an inch above the level of the surrounding skin, so that the whole growth was crateriform in appearance. It was very vascular, several large veins ramifying on the surface, and bleeding was easily induced on manipulation. There was no pain but the growth was very tender and the whole was soft, including the edges of the ulcer, which although heaped up were not indurated; the mass was freely moveable and none of the neighbouring glands were involved. A diagnosis of rodent ulcer was made but it could not be confirmed as the patient refused to allow a piece to be removed for microscopic examination.

I began the treatment with the x rays on March 5th, 1904, giving two sittings a week of five minutes each. No change was noticed until after the fifth application, when the surrounding skin, which was not completely covered by the mask of lead-foil I was using as a shield, showed some signs of inflammation. At the next sitting the ulcer had increased in size and after that the elevation of the growth became less marked as the treatment was continued, until after the sixteenth sitting the ulcer was level with the surrounding skin and of about the size of a half crown. As the reaction was marked the treatment was stopped for ten days and the ulcer was dressed with boric ointment. When next seen by me the ulcer was smaller, showing a healthy healing edge, and after four more applications of the rays it had quite healed, just over three months from the first application. At the time of writing, seven months since the ulcer healed, there is no sign of recurrence and no scar is visible.

Chatham.

IODOFORM AND MERCURY IN THE TREATMENT OF TUBERCULOUS PERITONITIS.

By DAVID SANDLER, M.B., CH.B. EDIN.

THE following case of successful treatment of tuberculous peritonitis with iodoform and mercury seems worthy of being recorded.

On May 25th, 1904, I was called to see a female child about six years of age, who was unable to stand and had been bedridden for over seven months. The treatment of several local practitioners as well as the assiduous employment of all sorts of domestic remedies, so much in vogue in this part of the world, seemed to do no good. The parents of the child regarded the case as hopeless and consulted me simply for the sake of novelty as I had newly arrived here. The patient presented a pitiful appearance. She was reduced to a perfect skeleton, her limbs, both upper and lower, being mere bone and skin. Her face was pinched, sallow, old looking and had a remarkably monkey-like expression. Her forehead was covered with wrinkles. Her lips were coated with a foul mass of yellowish-brown sordes. Her head was studded with large boils, some of which were hard and some were fluctuating. Her abdomen presented a wonderful contrast to the extremely emaciated appearance of the trunk and limbs, being very much distended, hard to the touch, and pigmented. Many small nodular masses could be felt through the skin. Several foul bedsores were seen on the buttock. The fæces were liquid and foul smelling. The morning temperature was subnormal, being 96° F. Sometimes slight fever was present. Immediately I had begun treatment the temperature rose on one or two occasions to 102°. There was no difficulty in diagnosing chronic tuberculous peritonitis. I prescribed powders consisting each of half a grain of mercury with chalk and half a grain of iodoform, one powder to be taken in milk three times daily. I also directed equal parts of ointment of mercury and ointment of iodoform to be rubbed, morning and evening, each time for about ten minutes, over the whole abdomen. Under this treatment, which was continued for several months, the child gradually improved. The boils rapidly disappeared. Already in about two weeks there was a very marked subsidence in the distension of the abdomen with a corresponding disappearance of the small nodular masses When the stools ceased to be liquid and foul smelling I ordered also half a teaspoonful of cod liver oil thrice daily. At present the child is almost perfectly healthy. Her face and body generally present a full, well-nourished appearance. Her gait, however, is somewhat unsteady, due undoubtedly to the fact that she has been confined to bed for a long period and has almost forgotten how to walk.

Constantinople.

MEDICAL MAGISTRATE.—Mr. Charles Augustine Hayman, M.D. St. And., F.R.C.S. Irel., L.R.C.P. Irel., L.D.S. R.C.S. Eng., assistant dental surgeon to the Bristol Royal Infirmary, has been placed on the commission of the peace for the city and county of Bristol.

COST OF SMALL-POX PATIENTS.—At a meeting of the Chard (Somerset) rural district council, held on July 17th, a discussion took place with regard to small-pox and it was decided that should any cases arise in Chard they should be removed to Langport where the authorities would be willing to receive them at seven guineas weekly for each patient.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

ST. THOMAS'S HOSPITAL.

A CASE OF PRIMARY CARCINOMA OF THE APPENDIX VERMIFORMIS.

(Under the care of Mr. W. H. BATTLE.)

FOR the notes of the case we are indebted to Mr. F. O. Spensley, dresser.

A schoolgirl, aged 14 years, was transferred to Beatrice ward from the gynæcological ward, where she had been admitted under the care of Dr. W. W. H. Tate, on July 15th, 1904. She was sent to the hospital by Mr. T. F. Okell of Long Ditton. Her father was said to suffer from pulmonary tuberculosis but the rest of the family were healthy. She is stated to have suffered from an attack of pain in the right iliac region with vomiting on four occasions. The first illness began on July 13th, 1903, and she was ill for two months. The second, which was the most severe, was in August, 1903, and she was ill for two weeks. The third attack was in September of the same year and also lasted for two weeks, whilst the fourth attack in July, 1904, only lasted for a few days.

On admission she was a healthy-looking, well-nourished girl, presenting nothing abnormal in her general condition. She complained of no pain or sickness. There were some resistance to pressure and slight fulness in the right iliac region over the appendix, otherwise the abdomen was natural.

On July 15th Mr. Battle removed the appendix. An incision three inches long was made midway between the anterior superior spine and the crest of the ilium. The rectus sheath was then opened, the muscle was separated and drawn inwards, and an incision was made through the posterior layer of the sheath and peritoneum. (The area of operation was shut off from the rest of the peritoneal cavity with strips of sterilised gauze.) On opening the peritoneum a large mass of omentum was exposed, matted and extensively adherent to the bowel. This was turned forwards and the appendix was found; it was then separated, not without difficulty, and removed, the stump being sutured into the wall of the cæcum. The parts exposed during the operation were washed with warm sterilised salt solution and returned to the abdomen. The opening in the structures behind the rectus abdominis was closed with interrupted silk sutures. The muscle was permitted to return to its position; the anterior part of the sheath was then closed with interrupted silk sutures and the skin with a continuous horsehair stitch. No enlarged glands were found. The appendix was twisted on itself and closely bound down, there being considerable fibrinous exudation all round it. Measuring about two inches in length, it was congested and its wall and mucous lining were much thickened. It presented two constrictions after removal, one near the distal extremity which cut off a marble-like portion in which was a collection of thick purulent fluid; the other was about two-thirds of an inch nearer the cæcum; and between them was a rounded nodule of about the size of a small marble which presented a yellowish white appearance on section somewhat the colour of a caseating mass of tubercle but of firm consistence. This caused a block in the lumen of the appendix When examined microscopically in the clinical laboratory a report was returned by Dr. C. F. Selous: "Spheroidal-celled carcinoma not arising from mucosa. Deep extension in muscular wall. ? Secondary to a visceral growth." The wound healed per primam. There was no rise of temperature or local pain. The patient left the hospital on July 28th and has since continued in good health.

Remarks by Mr. BATTLE.—Carcinoma of the appendix is more frequent as a primary disease in females than in males and the most striking thing about these cases is the age at which the disease has been found. Almost all the younger subjects were women and the youngest, so far as can be ascertained, was a girl 12 years of age, then one of 15, &c. It is not, however, suggested that it is a common complaint —far from it; only about 40 instances have so far been placed on record.

This is a very good instance of the manner in which cases of carcinoma of the appendix come under the notice of the surgeon. A patient is under treatment for attacks of appendicitis, and after operation some unusual change is observed in the appearance of the excised part which causes a microscopical examination to be made and a report of carcinoma is returned. Or the carcinoma is found at a post-mortem examination, when its presence had been quite unsuspected. The effect is very similar on the distal part of the appendix to that of a stricture of the lumen, and an attack of what appears to be of an ordinary inflammatory nature first draws attention to the fact that the appendix is diseased. This complication of the disease probably explains the fact that carcinoma in this part of the body seldom gives rise to secondary deposits; the patient dies, or the growth sloughs, or the appendix is removed. In a case described by Lejars in 1896 the growth rapidly recurred and disseminated, although at the time of operation the appendix appeared normal before it was cut open.

VICTORIA HOSPITAL, KINGSTON-ON-THAMES.

A CASE OF STRANGULATED CONGENITAL HERNIA CONTAINING A MECKEL'S DIVERTICULUM; OPERATION; RECOVERY.

(Under the care of Mr. J. E. S. BARNETT.)

THE patient, a man, aged 23 years, was admitted into the Kingston Victoria Hospital on the night of July 7th last. He was ruptured two years ago while lifting a gun-carriage when a soldier in India. He went to Bangalore Hospital and was invalided out of the service. This hernia was probably an epiplocele and his recent acute trouble arose from the sudden descent of an enterocele. He had been rowing the same day on the river without a truss. He vomited, was pale, sweating, moaning with pain, and begged to be relieved. Taxis had been tried outside the hospital by a medical man. The tumour extended from the left inguinal internal ring to the scrotum; it was narrow above, broad below, and very tense. Transfixion and subsequent dissection revealed a somewhat thickened sac, on opening which no fluid escaped but a considerable amount of omentum. The loop of gut was congested and tightly distended. A Meckel's diverticulum protruded from the posterior portion of the loop; this was not noticed till reduction was being effected. The canal and the processus vaginalis were very narrow and the neck of the sac barely admitted the tip of the little finger. It was necessary to snick this neck three times before reduction was possible. The vas deferens was so adherent to the back of the sac that no attempt was made to separate it completely. The upper end of the divided neck was twisted and ligatured high up and a ligature was tied round the lower end, the vas deferens being isolated. Sutures were passed between the conjoined tendon and Poupart's ligament. On July 10th the patient complained of slight pain in the wound and of "starvation" diet. There were no serious symptoms. At the end of a week skin stitches were removed and the wound had healed by first intention. His good condition must be attributed to the short period allowed to elapse between the strangulation (7 P.M.) and the operation (11 P.M.) and to the fact that no undue efforts at taxis were perpetrated.

GRIMSBY AND DISTRICT HOSPITAL.

A CASE OF ACUTE DILATATION OF THE STOMACH AFTER AN OPERATION ON THE KIDNEY.

(Under the care of Mr. C. B. TURNER.)

FOR the notes of the case we are indebted to Mr. S. B. Gadgil, house surgeon.

The patient, a married woman, aged 36 years, was admitted into the Grimsby and District Hospital on Jan. 14th, 1905, at 10 P.M., with anuria of three days' duration, sickness, and a temperature of 100° F. She had a history of rigors when at home. On examination a large tumour was felt in the right lumbar region of about the size of a fist, which was fluctuating and tender. Mr. C. B. Turner, who had removed her left kidney a couple of years back, having examined the case, came to the conclusion that she was suffering from pyonephrosis and decided to operate immediately.

Taking into consideration that the patient had only one kidney Mr. Turner simply drained the tumour through the lumbar incision, when a large amount of urine with pus came out. No stone was felt and on account of the nature of the case no more exploration was made. A drainage tube was put in and the patient was sent back to bed. She felt better on the next day. The temperature was 98·4° 12 hours after the operation but the vomiting did not stop. She also passed urine per urethram. After another 12 hours the temperature fell to 97° and the pulse remained very feeble and slow. Stimulants were tried but nothing was done in the way of washing out the stomach for the vomiting which kept on as before. The vomit was reddish, dark, and brown in colour and very profuse in quantity. On the next morning —i.e., 36 hours after the operation—she lost more ground. Her temperature was 96° and she died about eight hours later.

Necropsy.—At the post-mortem examination the kidney had its capsule very adherent, due to inflammation (past), and it contained two stones, one in the pelvis of about the size of a marble and the other in the tissue, which was smaller. There were also two or three suppurating foci in the tissue of the kidney. The pelvis of the kidney was moderately dilated. But the remarkable point was the size of the stomach. The lower curvature of the stomach was very much below the level of the umbilicus and hardly any part of the intestinal canal could be seen. The stomach wall was attenuated, so that when the abdomen was opened and nicked a couple of pints of dirty fluid simply welled out and after tying the opening the stomach was found to be still full of fluid.

Remarks by Mr. GADGIL.—Acute dilatation of the stomach being a rare complication after operations on the kidney I thought it well to record the above case.

The persistent vomiting and the absence of desire for food should have led me to do something for the stomach in the way of lavage but whether it would have been of any use I cannot say. Perhaps someone who has met with a similar case may be able to tell his experience.

That the case was one of acute dilatation is inferred from the fact that the woman never complained of any gastric troubles before and that the anuria was not due to pressure of the stomach contents on the ureter is shown by the fact that she passed urine per urethram *after nephrotomy.* During this operation I believe the pressure upon the ureters was relieved. There was a *stone found in the pelvis* of the kidney which not being taken away at the operation could not have been the cause of anuria. The stomach was left undisturbed throughout the whole course of the complaint.

I have to thank Mr. Turner for allowing me to report the case.

Reviews and Notices of Books.

Squint: its Causes, Pathology, and Treatment. By CLAUD WORTH, F.R C S Eng. Second edition. London: John Bale, Sons, and Danielsson, Limited. 1905. 8vo, pp. 231. Price 6*s*.

THIS treatise belongs to a class of works which are happily becoming more and *more* numerous and in which a surgeon whose opportunities of observation are large selects a particular form of disease, studies its varieties, obtains accurate statistics of age and sex, endeavours to ascertain its pathology, and notes the effects of different methods of treatment. It is only in this way that real advances can be made.

The various opinions that have been held in regard to the causation of squint form an edifying commentary on the effects of more exact knowledge upon our theories of the nature of disease. If even a well educated medical man had been asked so late as at the *middle* of the last century to what cause he would attribute the occurrence of squint he would have replied that it was due to weak-sightedness, imperfect vision from short-sightedness, or some congenital defect of the retina causing the squinting eye to be very considerably inferior in power of sensation to the other. It was known, even at that time, that the muscles presented no appreciable change and it was considered that the defect was occasioned either by some opacity of the cornea or by some lesion of the retina. Additional and subsidiary causes were found in hereditary predisposition, in the child being allowed to hold his book too close to the eyes, in imitation, and in the habit of looking at the point of the nose, and it was noticed that it frequently followed irritation of the nerves or the brain by worms or teething, or inflammation of the brain itself. After the appearance of Donders's well-known treatise, in which he demonstrated the connexion of convergence with accommodation, it was generally believed that hypermetropia was the fundamental cause of the affection. But it was soon ascertained that high degrees of hypermetropia are by no means constantly associated with squint and that although an important factor in the maintenance of that affection when once established, it could not be accepted as the exclusive cause. Mr. Worth now comes forward with another theory which regards convergent squint as the result of an imperfect development of the fusion faculty. This faculty he believes to be acquired as a rule in early infancy, reaching its full development about the sixth year. This view has an important bearing upon the treatment which he adopts. That treatment consists in training the fusion faculty by means of an instrument named the amblyscope, of which he gives a drawing and description. Fusion training, Mr. Worth considers, to be of any material benefit must be undertaken at a very early period. Before the age of five years it may be in suitable cases quickly and easily accomplished. After the age of six, or at the latest seven, years the results are not worth the time and the trouble which they cost. The deviating eye, it is hardly necessary to say, must not be too blind. Divergent squint, Mr. Worth states, presents two distinct varieties, the myopic and the neuropathic. In the myopic form the fusion sense is usually well developed and the squint develops gradually. It may often be cured by the use of appropriate glasses. The neuropathic form is less amenable to treatment by means of glasses and an operation effecting advancement of the tendon of the internal rectus is frequently necessary to remedy the defect. The author cites a number of cases that have been under his care of the ordinary forms of squint as well as others which illustrate the rarer forms of heterophoria that are highly instructive and we commend the book cordially to the attention of every ophthalmic surgeon.

An Atlas of Dermatology, showing the Appearances, Clinical and Microscopical, Normal and Abnormal, of Conditions of the Skin. By MORGAN DOCKRELL, M.A., M.D. Dub., Senior Physician and Chesterfield Lecturer on Dermatology to St. John's Hospital for Diseases of the Skin. With 60 coloured plates. London: Longmans, Green, and Co. 1905. Price 50s. net.

THE scientific study of dermatology has been delayed until comparatively recent years owing to the lack of knowledge of the morbid histology of cutaneous diseases. The microscopic pathology of the internal organs had attained a high degree of perfection before the study of the morbid histology of the skin had even been commenced. Two reasons are given in explanation of this somewhat remarkable fact. Firstly, the symptoms of skin diseases, unlike those of internal diseases, are visible to the eye of the physician and seem at first to be so definite and distinct that the need of histological knowledge is not urgently felt; and secondly, cutaneous diseases being rarely fatal sections from the cadaver are not frequently obtainable. As the clinical study of cutaneous diseases advanced descriptions of naked-eye observations made by various competent dermatologists became so involved and the nomenclature and classification in consequence so vast and intricate that the necessity of histological investigation became increasingly evident. Not until biopsy—i.e., sections of skin for microscopic examination taken from the living subject—was introduced and welcomed as a harmless and almost painless operation did the study of cutaneous diseases begin to make scientific progress in keeping with the advance in other departments of medicine and surgery in the latter part of the nineteenth century. The practical use of this recent development comes into play in the diagnosis and consequently affects the treatment of diseases which may baffle the skill of the most experienced with naked-eye examination alone. Thus, a lupus erythematosus is readily distinguished under the microscope from a lupus vulgaris, yet the very names of these diseases betray their frequent clinical similarity.

Many atlases have been published showing the clinical aspects of cutaneous diseases, and several excellent books, notably the monumental work of P. G. Unna, have been written on the histo-pathology of the skin. So far as we are aware the atlas before us is the first to attempt to combine the clinical and the histological appearances of cases of disease of the skin met with in everyday practice. The International Atlas of Rare Skin Diseases (conducted by Unna, Morris, Duhring, Leloir, and Besnier), which first appeared in 1889, contained in most cases illustrations of the microscopic sections as well as of the clinical appearance of the diseases dealt with, but, as the title informs us, that atlas was concerned only with a few rare diseases. We therefore welcome an atlas which supplies a distinct want at the present day and congratulate Dr. Dockrell on producing one at once so accurate and so artistic. The book is portable, handsomely printed, and contains two additional illustrations of the normal skin, which can be removed for purposes of reference or comparison.

The microscopic plates, with the exception mentioned below, call for high praise. Dr. Dockrell is fortunate to have in Mr. Colhoun a histologist who has reproduced with such careful accuracy the minute details that make up a faithful picture of a microscopic specimen. To understand a section prepared for examination under the microscope it is all important to recognise the varieties of cells met with in the tissue examined—leucocytes and connective tissue, epithelial, mast and plasma cells. With this object Dr. Dockrell has devoted Plate IV. to the representation of cells. The degenerate "balloon cell" which is met with chiefly in herpes zoster is clearly depicted in Plate IV. It is a matter for regret that on Plate XLIII., which deals with herpes zoster, the reader is not referred to Plate IV., because of the two plates the latter has much the better picture of a "balloon cell." The various fungi of the hair and the skin are illustrated in this atlas and we are disappointed to find that these are somewhat blurred in outline; the spores and mycelial segments of the ringworm fungi do not show the sharp definition seen in a stained microscopic preparation, nor are the differential points of the small and large spored ringworm fungus brought out as distinctly as we have seen in many black-and-white drawings in ordinary text-books.

The illustrations of the clinical appearances of skin diseases are highly to be commended, but owing to the method of colour reproduction many of the plates fail to give a lifelike outline and colour. Thus, a greenish-yellow hue predominates in Plate IX. (seborrhœic dermatitis), while the letterpress draws attention to the brick-red colour of the lesions. Again, in Plate VI. (vesicular eczema) the vesicles would scarcely be recognised to be such. These faults, it is true, may be found in all atlases and are not due to an error on the part of the artist. While the majority of the plates in this atlas reach a high level, yet some of the plates fall short of the life-like representation obtained by the four-colour process, known as citrochromy, in Professor Jacobi's portfolio of dermochromes, with which, no doubt, most of our readers are familiar. The only illustration in regard to which we consider that the artist is open to adverse criticism is that of small-pox. The size of this plate is inadequate; the lesions in consequence are so crowded and each is so minute that it is impossible to distinguish the umbilication referred to in the letterpress. The lesions of varicella might also with advantage be enlarged. We mention these few drawbacks because they stand out in an otherwise excellent atlas.

With regard to the letterpress, the author admits that this is somewhat brief but this is certainly an error on the right side. Dr. Dockrell uses few words but these are always to the point. His lucid and convincing style is admirably seen in his differentiation of lichen acuminatus and pityriasis rubra pilaris; the accompanying plates (XII. and XIII.) bear out his contention that in pityriasis rubra pilaris the hair follicle is involved from the first and that the infiltration is greater than in lichen acuminatus, while the epithelium does not undergo the hyaline change met with in lichen.

This atlas will be of use to the practitioner or senior student who has not time or opportunity to undertake courses of instruction in the clinical and microscopic study of dermatology in a hospital or laboratory; it will also form a valuable aid to those more fortunately circumstanced who are enabled to devote the necessary time to the practical study of the subject.

LIBRARY TABLE.

Paludisme et Trypanosomiase. Par A. LAVERAN, Membre de l'Institut et de l'Académie de Médecine. Paris: J. B. Baillière et Fils. 1905. Price 2 fr. 50. Pp. 124.—In this small work we find a most complete *résumé* of the actual state of our knowledge of these two maladies. The section on Malaria, constituting the greater portion of the work, is just what would be expected from its author who is so well known in connexion with this subject. M. Laveran commences by detailing the geographical regions affected by the disease; he then narrates the general conditions favouring its outburst, such as those connected with season, humidity, altitude, and so on. The question of congenital paludism is answered by a possible affirmative. Then the history of the provocative agent is entered upon and the subject is traced from the last century up to the present time. The author, as is well known, in 1880 first described the hæmamœba malariæ and in 1884, in his treatise on "Marsh Fever," advanced the opinion that the parasite had a stage of its being outside the human body and probably in the mosquito. This was ultimately proved to be the case by the researches of Ross, supplemented by those of Grassi, Bignami, Bastianelli, and Manson. The parasite is well described in its different stages, with the manner of its evolution in the body of the mosquito. Mention is made of the experimental proof by T. Manson who contracted tertian ague from an infected mosquito's bite sent from Italy after biting there a patient suffering from that disease. With respect to the question whether there are several species of the hæmatozoon, M. Laveran states that he does not admit this to be the case. The method of the examination of the blood is well described. The author deals with the period of incubation, which he holds to be from six to eight days at a minimum. The clinical forms of the disease are described—the intermittent, the continued, the pernicious, the larval, and finally the cachexial. The description of the pernicious class is particularly lucid. We then come to the various complications that may be met with, namely, those of the spleen, liver, kidneys, lungs, heart, glands, nervous system, bones, and affections of the organs of vision. The relationships of dysentery and enteric fever are discussed, as are also those of tuberculosis, diabetes, scurvy, and small-pox with malaria. After a section on the post-mortem appearances we come to the question of diagnosis and here the importance of an acquaintance with the microscopical appearance of the hæmatozoon is insisted on. The various points in the differential diagnosis are explicitly detailed. A few words on prognosis follow and the section concludes with the subject of treatment. As regards quinine, it is well stated that although it may be better to give it during the apyrexial periods yet we cannot wait to do this in the grave forms of the fever. With respect to prophylaxis the methods are the destruction of the mosquitoes, the protection against their bites, the treatment of malarial patients, and the rendering individuals immune to the disease. The concluding part of the work deals with Human Trypanosomiasis and Sleeping Sickness. The medical history of this disease is first given and the various theories formerly in vogue are described, and then are detailed the steps during which the trypanosoma was finally adjudged to be the cause of the disease. The geographical distribution is shown, the predisposing causes of the malady connected with sex, age, race, and so on, are mentioned, and then we come to the description of the disease in its first and second periods. The pathological anatomy, the description of the parasite, its dissemination by the glossina palpalis, the diagnosis of the disease, and its prognosis and its treatment successively follow. With respect to the last, iron, quinine, and arsenious acid are recommended. As regards serotherapy no definite opinion is expressed as it is still under discussion.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. New Series, No. 14: On a Parasite found in the White Corpuscles of the Blood in Dogs, by Captain S. P. JAMES, M.B. Lond., I.M.S. Calcutta: Office of the Superintendent of Government of India Printing, India. Pp. 12. Price 10 annas or 1s.—The author records in this memoir some observations that he has made on a leucocytic parasite which is not uncommon in the peripheral blood of dogs in Assam. The observations are extremely interesting as there is no previous record in literature of the discovery of parasites of the white blood corpuscles of mammals. Captain James first refers briefly to the work of Danilewsky, Sacharoff, Ziemann and others regarding the leucocytic parasites found in the screech owl, crows, rooks, and magpies, and concisely summarises the researches of Schaudinn on these micro-organisms, according to whom the so-called leucocytozoa of the latter are the resting asexual stages of his trypanosome like parasite, the nucleated mass in which those observers thought the parasite was contained being in Schaudinn's opinion neither a leucocyte nor a red blood corpuscle but an erythroblast to which the parasite has attached itself, and which, with the exception of the nucleus, it absorbs into its own substance. With regard to the parasite which is the subject of this memoir, in June, 1904, the author relates that his attention was directed to a peculiar body in the leucocytes of the blood of a dog by Dr. C. A. Bentley of Assam and in subsequent examinations it was found by the author in the peripheral blood of six out of 45 dogs, either alone or with other parasites. In number the bodies varied a good deal, from one parasite in every 11 polymorphonuclear cells to one in every 64. Especially noted was the presence of nucleated red blood cells in considerable numbers. The blood films were examined, fixed in alcohol, and coloured by Romanowsky's method. The parasites were found to be contained almost invariably in polymorphonuclear leucocytes and it was necessary to stain deeply the films in order to bring out their structure distinctly. They were found to consist of two parts—(1) a definite oblong, almost quadrilateral cytocyst, with (2) a parasite inclosed within this cytocyst. The facts relating to the position of the parasite in the leucocytes and its effect upon them are then narrated. Captain James believes that two forms are always present in the peripheral blood of infected dogs. He thinks that the parasite represents a hitherto entirely unknown form of mammalian blood infection, inasmuch as it is parasitic entirely upon the leucocytes, and suggests for it the name of "leucocytozoon canis." A clear plate accompanies this interesting memoir.

"*Verb. Sap.*" *on Going to West Africa, to Northern and Southern Nigeria, and to the Coasts.* By ALAN FIELD, F.R.G.S. London: John Bale, Sons, and Danielsson, Limited. Pp. 166. Price 2*s.* 6*d.* net.—This little work constitutes an excellent guide on all matters appertaining to the countries named in the title. It opens with a preliminary note on the outfit that an official should provide himself with and we are glad to see that the fact is emphasised that woollen vests must be worn under the body linen in order to obviate "fever." The expenses of a good outfit are put down as £100. A descriptive article on the voyage from Liverpool to Lokoja follows, after which there are eminently practical chapters on the Climate and Health and the Mode of Life in the above regions. Here the reader will find all the essential points for preservation of the health. The precautions to be taken with regard to malaria are excellent; especially valuable are those having reference to mosquitoes. Here we note with pleasure that the mosquito nets are directed to be tucked under the mattress and hung inside the rods or poles and not outside. The remarks regarding sunstroke are equally valuable; stress is laid on the fact that an attack can be caused through the eyes. There is, however, no mention of the advisability of lining the helmet with red cloth, which experience in India has shown to be very efficacious. The book also contains notes on sport, languages, and so on, and, in fact, everything concerning which a newcomer would require information.

JOURNALS AND MAGAZINES.

The Practitioner.—In addition to cases of particular interest narrated by Sir Dyce Duckworth and Mr. A. W. Mayo Robson the July issue of the *Practitioner* has an attractive little series of articles under the heading, The Effect of Tobacco in Health and Disease. Sir Lauder Brunton deals with the heart and the circulation and he consoles the smoker by the reflection that "smoking in moderation does not seem to be injurious to grown-up people." Dr. Norman Dalton, in connexion with the gastro-intestinal tract and tobacco, agrees with Dr. T. Clifford Allbutt that in certain persons a hyperchlorhydria is produced with an intense heartburn which is relieved by food. Dr. James Taylor discusses the effects of tobacco on the nervous system and Mr. W. G. Spencer those upon the mouth and the tongue.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S.; D. J. CUNNINGHAM, M.D., F.R.S.; G. S. HUNTINGTON, M.D.; A. MACALISTER, F.R.S.; and J. M'KENDRICK, F.R.S. Vol. XXXIX., Part IV. July, 1905. London: Charles Griffin and Co. Pp. 145. Annual subscription, 21*s.*—The articles contained in this number are as follows: 1. On the Origin of Vertebrates, deduced from the study of Ammocœtes, by Walter H. Gaskell, F.R.S., Part 12. 2. On Pressure Epiphyses, by F. G. Parsons, F.R.C.S. 3. On Imbrication of the Papillary Ridges in Man, by Walter Kidd. 4. Skulls from the Round Barrows of East Yorkshire, by William Wright, F.R.C.S., with six plates. The skulls are described in a very technical manner. For example, Skull 33 is that of a female; it is brachycephalic, hypsicephalic, chamæprosopic, orthognathous, and mesorhine, besides presenting other characteristic features. Skull 46 is a male skull. It is mesaticephalic, orthocephalic, mesognathous, leptoprosopic, and mesorhine. The plates which accompany the article are from excellent photographs. 5. The Anatomy of a Sirenomelian Monster, by Gillman Moorhead, M.D. 6. Cranio-cerebral Topography, by G. J. Jenkins, M.D. 7. The Development of the Retina in Amphibia: an Embryological and Cytological Study, by John Cameron, M.D. Edin., with two plates, Part 3. The author recognises four groups of structures in the inner wall of the retinal cup—namely, germinal nuclei, neuroblast nuclei, spongioblasts, and myelospongium The processes of the cells in the ganglionic and internal nuclear layers emerge from the nuclei and not from any surrounding cytoplasm and the first rudiments of the rods and cones are partly in the form of protrusions of nascent achromatin from the external nuclear layers. This substance attacks the yelk granules and transforms them into clear achromatic "yelk globules." The rod and cone rudiments ingest the pigment of the pigment cells and metabolise it into a substance which stains very intensely with iron alum-hæmatoxylin and is apparently rhodopsin. The so called "oil globule" of the amphibian cone is simply the remains of the original yelk globule. 8. A note on the Variations of the Tibia and Astragalus, by D. Macrae Aitken, F.R.C.S. Edin. 9. On the Limits of the Sensibility to Odours and of the Methods of detecting Emanations, by M. Berthelot. 10. A Curious Abnormality of the Renal Arteries, by Charles R. Whittaker, F.R.C.S. 11. Abstract of a paper on Ossification of the Lower Jaws of Man, by Edward Fawcett, M.B. Edin. This part of the journal also contains the Fifteenth Report on Recent Teratological Literature, by Bertram C. A. Windle, M.D., F.R.S., and the index of the thirty-ninth volume of the journal.

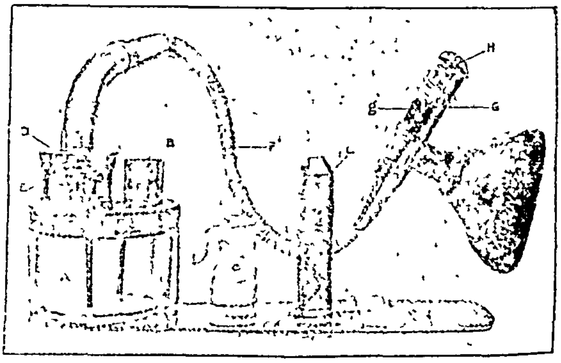
Transactions of the Bombay Medical and Physical Society. Vol. IX., No. 2. April, 1905. Bombay: Printed at the Times Press. 1905. Pp. 23 and six plates.—This issue contains the report of a clinical meeting held in the University Library on April 17th. Among the papers read were two on cases of Leishman-Donovan Disease by Major L. F. Childe, I.M.S., and by Major C. H. L. Meyer, I.M.S., and a most interesting one from the F. D. Petit Laboratory, Bombay, by Dr. R. Row, on Obscure Irregular Continued Fevers of the Typhoid Group and their probable relation with different species of bacilli of the typhocoli race, as seen from the specific bacteriolytic value of blood serums of such cases on various members of the typho-coli group of microbes. This paper is illustrated with excellent plates. The author states that his study of fevers of a continuous type familiar in Bombay—fevers characterised by their atypical and irregular course, by pronounced abdominal and later by typhoid symptoms, with the blood sterile and free from malarial, relapsing, or other parasites—leads him to concur with the views of Major D. B. Spencer, I.M.S. (*Indian Medical Gazette* April, 1900), that apart from the genuine enteric fever (produced by Eberth's bacillus) met with in India, practitioners have often to deal with a group of fevers which though generally styled "typhoid," are in reality intestinal infection produced, as he believes, primarily by a single type of bacillus or a mixture of enteric bacilli (distinct from, although closely allied to, Eberth's bacillus typhosus) setting up a simple or a complex reaction on the part of the patient and in some cases a complex phenomenon resulting from secondary infections superimposed in the course of reaction set up by the primary cause. Dr. Row says that Major Spencer's observations from a clinical point of view are in harmony with his own and that they strongly support the inferences enumerated in this paper which are drawn from bacteriological evidence.

New Inventions.

A NEW CHLOROFORM AND ETHER REGULATING INHALER.

THE aim of the anæsthetist when administering chloroform should be to give a constant minimal dose and to maintain an unvarying depth of anæsthesia, but by the rough-and-ready method with mask and drop bottle it is almost impossible to attain this ideal except at the hands of experts, and even then only approximately. By the old methods the dosage is necessarily far from accurate and is therefore unsatisfactory; it is, moreover, on account of this inaccuracy, this varying dose of chloroform, and varying depth of anæsthesia that dangers during narcosis from chloroform usually arise. Most anæsthetists therefore welcomed the advent of the Vernon-Harcourt regulator and it was doubtless a revelation to many of us that a very large number of patients can be kept sufficiently anæsthetised with fractions of 1 per cent. of chloroform vapour in the inspired air. The apparatus is, however, very cumbersome and inconvenient and in my hands it is incapable in many cases—for instance, extensive abdominal operations in certain types of patient—of giving a sufficient dose of chloroform for all contingencies and to suit all surgeons. It has, moreover, certain other inherent disadvantages, such as the restriction of its air-ways by several right-angle bends. For these reasons it has, in spite of its virtues, been discarded by many. I have therefore devised, and Messrs. Krohne and Sesemann have very carefully made after many experiments, the apparatus illustrated below, which enables the anæsthetist to attain the ideal I have predicated and which is without any of the disadvantages of the Vernon-Harcourt apparatus. The two indispensable points about any chloroform inhaling apparatus are that it should be capable of giving a sufficient dose to any kind of case under any ordinary surgical conditions and that it should offer no obstruction to the patient's respiration, which is easily depressed by chloroform. In this apparatus the air-ways are made five-eighths of an inch in diameter, so that there is absolutely no sense of oppression in breathing through them. The apparatus is capable of giving all percentages from zero up to an approximate maximum of 4 5 per cent. I have made no attempt to limit the dose to a so-called "safe" percentage, as I think it is a wrong principle to put an apparatus for giving chloroform into the hands of inexperienced persons and lull their legitimate fears by telling them that it is "safe" Chloroform can never be quite safe and only harm can result by trying to make people think otherwise. It is a mistake to minimise the necessity for the very closest attention on the part of an administrator and to take away the necessity for his judgment and initiative. In the inhaler now to be described an ample percentage of chloroform can, if desired, be obtained for all conditions, and this is particularly useful in those cases where it is very difficult to fit the face-piece with perfect accuracy; in such instances a little admixture of air round the face piece can be compensated for by increasing the percentage in the chloroform delivery.

The apparatus consists of a graduated glass reservoir (A) four inches in diameter by three inches deep. The reservoir is made of this large sectional area to enable ether to be quickly evaporated, since when the apparatus is used as an ether inhaler it is necessary that the inspired air shall pass in close contact over a large area of ether in order that it shall take up sufficient ether vapour. The reservoir is fitted, by means of a bayonet catch, with a metal lid; this lid is perforated by two openings, the air inlet at B and the outlet at E, for the mixture of air and chloroform vapour: this latter opening is closed with a balanced valve. Both openings are five-eighths of an inch in diameter. B is a slotted metal collar around the air inlet which takes the "increase tube" C; the variations in the position of this tube alter the strength of chloroform vapour in the inspired air, since by its means at each inspiration a column of air is made to impinge more or less directly and forcibly upon the surface of the anæsthetic fluid. Thus when it is at its highest point and with one ounce of chloroform in the reservoir the volume of chloroform vapour in the inspired air is 3 per cent. to 2½ per cent. depending upon the frequency of the respiration and the temperature of the chloroform; when at its lowest point the volume rises to 3½ to 4 per cent. depending upon the same conditions, and when the "increase tube" is removed the volume is only 0·75 per cent., which may be further reduced at will by revolving the air inlet collar (g) to admit more air and thus dilute the chloroform vapour. This dilution can be made irrespectively of the position of the "increase tube" if this plan of reducing the dose of chloroform be preferred. The "increase tube" C is fitted with a metal grooved ring (c) to which a petticoat of gauze may be attached in such a way that when it is desired to give ether and when the tube is in place the end of the gauze dips into the ether, acting like a wick and thus increasing the area of evaporation. The orifice and valve (E) are inclosed in a glass valve observation chamber, to the lid of which is attached by a bayonet catch a piece of flexible aluminium tubing 18 inches in length (F); this connects the reservoir with the stopcock (G). The inspiratory valve E is so delicately balanced that the least lowering of pressure in the tube and valve chamber immediately causes the valve to rise and thus there is no sense of oppression in breathing through it. The face-piece is fixed to the stopcock (G), which is of standard size, so that any ordinary face-piece of Clover's inhaler or gas apparatus will fit it. It has an opening to admit air which is opposite the face-piece and when fully open is wide enough to take the whole of the respiratory stream, no air then passing through the apparatus over the surface of the chloroform; this orifice may be closed at will by a revolving collar (g) which is seen in the figure half across the opening. This collar carries, by means of another collar plugged upon it, the expiratory valve (H) which is guarded by a cross of stout wire. By means of its collar, which is made to rotate, the valve (H) may always be kept dependent in any ordinary position of the stopcock, so that it completely closes the expiratory orifice and does not tend to fall away from it. To the opposite end of the stopcock the flexible aluminium tube is fixed. All parts of the apparatus are detachable and can be easily removed for cleansing or repair. The reservoir is held in a convenient position close to the patient's head, where all its parts will be well in view and where it is out of the way of the surgeon or his assistants by means of the stand (I). This consists of a stout wire cage which closely fits round the reservoir and is fixed to a flat telescoping base. This base is made in two parts which may be pushed one upon the other until the length is reduced to ten inches, so that it can be carried easily in the anæsthetist's bag, or when in use it may be extended to 18 inches. By pushing the base of the stand under that part of the mattress on which the patient's shoulders rest on the bed or operating table the whole apparatus is kept perfectly rigid. If preferred the stand may instead be placed upon a table beside the patient, the length of the base when fully extended insuring sufficient immobility without the additional weight of the patient resting upon it. Since the reservoir is so close to the patient's head only a short length of tube is required and thus the respiration is not impeded; moreover, the air-ways are not encroached upon by angular bends. It will be seen that the apparatus is extremely simple, handy, and portable, and that there is nothing to get out of order.



The best way to use the inhaler is as follows. Half an ounce or more of chloroform is put into the reservoir—the quantity depending upon the probable duration of the operation—the "increase tube" is fixed at its highest point, the air inlet collar is revolved so wide that only the faintest taste of chloroform is perceptible when a breath is taken through the apparatus, the inhaler is placed in its stand, and the base of the stand is pushed under the patient in a convenient position. After applying the face-piece the air opening is closed very gradually by rotating the collar which covers it, thus gradually making more and more of the inspired air pass over the surface of the chloroform as less and less passes through the air inlet *in the stopcock*; in this way the percentage of chloroform in the inspired air is slowly increased. Experience will soon teach how rapidly this gradual increase of dose may be effected, but six minutes will usually be sufficient in which to induce anæsthesia. If the percentage of chloroform be not too quickly increased patients will, as a rule, quietly pass into the anæsthetic sleep without a struggle or sign of discomfort. Should, however, the subject be alcoholic or inclined to struggle, in spite of a very gradual administration, the "increase tube" may be placed at its lowest point and the percentage of chloroform thus considerably increased. After full anæsthesia has been established the patient will need very much less chloroform to maintain it, only sufficient, in fact, to make up for that which is eliminated at each breath. The percentage therefore should be reduced and kept at as low a point as is consistent with the requirements of the surgeon. When once the minimum point has been found nothing more is required than to keep the face-piece closely applied; the patient will then remain in an unvarying depth of anæsthesia because he will be inhaling a practically unvarying dose. In course of time, however, the chloroform in the reservoir will become cooler and other things being equal the percentage of chloroform in the inspired air will, from diminished evaporation, slightly fall; but since as the operation progresses the patient needs less chloroform this automatic diminution in the dose is an advantage. During the administration the anæsthetist must, of course, watch the condition of the patient closely and reduce or increase the amount of chloroform as may be necessary. Generally speaking, all he has to do is to keep the face-piece applied, but he must remember that chloroform can never be an absolutely safe anæsthetic and that its administration involves the gravest responsibility and risk, that in the administration of an anæsthetic more is involved than the mere exhibition of a certain dose of the anæsthetic drug, and that unless he *devotes* his closest attention to the matter in hand he courts disaster. With this apparatus he is enabled to administer an exact and constant dose in the simplest manner and provided he keeps the air-way free and works with as small a dose as possible an accident is a remote contingency.

In the event of the patient showing symptoms of shock in the course of a long or extensive operation ether may be added to the chloroform by pouring it down *the* "*increase* tube"; or if it be desired to change to ether entirely the remaining chloroform may be poured out of the reservoir and ether substituted, after placing the ring carrying the gauze petticoat (c) upon the "increase tube" *inside the reservoir* It is not recommended to induce anæsthesia with ether in this way, the better plan being to accomplish this with ethyl chloride or gas in another inhaler and then to change to ether in the regulator. In giving chloroform by this means the consumption is not more than one-third of that necessary by means of a mask and drop-bottle; if, however, ether be given the consumption is greater than when a closed inhaler is used, but the regulator possesses this obvious advantage that there is no re-breathing in and out of a stuffy bag, a process which is unhygienic in the highest degree. The patient instead takes in fresh air laden with ether vapour with each breath and in consequence of the freedom from asphyxia there is but little secretion, no sweating and therefore less *risk* of chill, no cyanosis, and the respiration is less *forcible*. The after-effects are naturally less. I have used the inhaler constantly both at the London Hospital and in private *practice* since last autumn and have experienced no trouble with it, and by the kindness of Mr. C. Carter Braine and Dr. J. Blumfeld I have been enabled to demonstrate its use twice at the Charing Cross Hospital in serious abdominal operations on patients weighing over 16 stones—one in the Trendelenburg position for over an hour—and once at St George's Hospital for an abdominal operation. In each instance the administration was conducted to the entire satisfaction of the surgeons and the anæsthetists on duty at the time. The apparatus is admirable for teaching purposes since the effects of definite percentages of chloroform *can* be easily demonstrated. The comfort of administration by its means and the freedom from anxiety can only be fully appreciated by actual trial of the instrument. I believe its general use would *materially* lessen the mortality from *chloroform*. The percentages were *estimated* by Mr. P. Richards, lecturer on chemistry at the Charing Cross Hospital Medical School, for whose kind help I am most grateful.

L R.C.P. Lond.,
Assistant Instructor in Anæsthetics at the London
Hospital and Anæsthetist to the Royal
Dental Hospital.

A DROP-BOTTLE FOR THE CHLOROFORM-ETHER ANÆSTHETIC MIXTURE.

DURING the past ten years I have found a mixture, consisting of one part of chloroform with two parts of ether by volume well shaken together, to be a most valuable anæsthetic when administered upon a honeycomb sponge by means of Dr. J. F. W. Silk's celluloid Rendle's mask. My own method has always been to hold the mask with the left hand close to, but not touching, the patient's face before the anæsthetic is poured on, and after instructing the patient to breathe slowly through the mouth to introduce the mixture upon the sponge in the flannel lining at the distal end of the mask by inserting the spout of a suitable drop bottle through the most convenient of the holes which are pierced through the celluloid for respiration. By this means a gradually increasing strength of vapour can be administered without removing the mask until the third stage of anæsthesia, with a weakly active corneal reflex, is attained. The bottle for this purpose should hold four ounces of the mixture and possess a bayonet catch to the stopper, so that it may be fixed open and the spout may then deliver a free stream of anæsthetic when the bottle is held by the body without the necessity of pressing the stopper with the index finger.

FIG. 1.

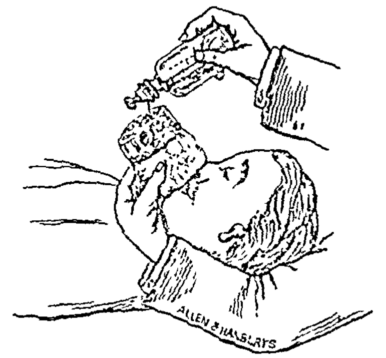

FIG. 2.

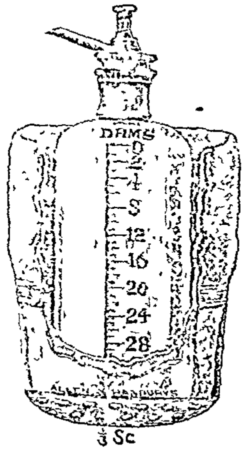

Messrs. Allen and Hanburys of Wigmore-street have made a bottle suitable for this purpose which packs easily into the mask for transit, as shown in the accompanying illustrations.

LONDON: SATURDAY, JULY 29, 1905

The British Medical Association: The President's Address.

THE Presidential Address of the British Medical Association, delivered by Mr. G COOPER FRANKLIN, surgeon to the Leicester Infirmary, and printed in our columns this week, forms an interesting contribution to one of the most important questions in medical politics Medical education is in a critical position in many ways, and all discussion which deals with the numerous questions pressing for solution will be welcomed by thoughtful members of our profession After a brief *résumé* of medical education before the Act of 1858 Mr FRANKLIN describes with some detail the curriculum of the medical student of the present day and as a result comes to the conclusion that the prescribed course of training is still, as it has been in times gone by, deficient in three particulars He considers that the quality of the preliminary examinations is poor, that insufficient attention is paid to obstetric medicine, and that practical experience in the administration of anæsthetics is not adequately provided for It is a relief to come across concrete objections to the present state of affairs instead of merely nebulous abuse of British technical training, or criticism of the proceedings of the University of London, or complaints of the inefficiency of the examination system, and Mr FRANKLIN will find his words to be all the more heeded that their purport is so straightly defined

One of the main defects in the present education of the medical student is undoubtedly constituted by the fact that certain of the examinations which form an introduction to the career of a medical man are not sufficiently stringent Mr FRANKLIN'S consequent proposal is that every medical student should pass an examination of equal stringency to the matriculation examination of the University of London. We quite realise that the increasing scope of medical knowledge makes it necessary that the medical student should be increasingly receptive but this proposal seems to us to be a little extreme The matriculation examination of the University of London, owing to improvements in its arrangement, is no longer the stumbling block to the student that it was, but it remains a test for which a lad of 17 or 18 years of age requires good teaching if he is to be brought up to the point of learning at which he is fairly sure to pass it Many lads of the indicated age, as well as many young women among their coevals, can pass it with ease, but some who are really abler students find it a most awkward check to their progress, a check which they can hardly surmount unless they are specially "coached" to that end It has to be remembered that boys of 17 are not all of the same age, some being men in their powers of concentration and in their early development, while others are veritable schoolboys By the age of 24 or 25, however, a levelling process will set in, the forward lad comes back to those whom he had distanced, the backward lad catches many of those who bade fair to outstrip him entirely. It is the chief argument against an examination of real stringency at the age of 17 that the barrier may prove unimportant to men who at the age of 24 prove themselves capable of no great intellectual achievement, while it may terribly impede the career of other men who, on arriving at the age when individual action is necessary, display themselves as the possessors of real originality It must be admitted that from the medical student's point of view the best thing that can happen to him is to have his career blocked at the outset by a thoroughly stringent examination—such an examination is a blessing in disguise Over and over again it has been found that the student who starts his career in possession of a good education of a general sort finds no difficulty in passing the professional tests to so many of which he has to submit himself later. And yet the matriculation examination of the University of London is too severe to form the portal to the medical profession The best course at the present moment is probably an intermediate one A stringent examination guards the portals of the Foreign Office, of the Home Office, of the Indian Civil Service, of the Treasury, and so on, but it must be remembered that those who pass it are, to a certain extent, made men. Their parents ought not to grudge for them the expensive education and special "coaching," because good interest is reaped on the capital expended But this position does not prevail in the case of the medical student and his entrance examination ought not to be made of the kind that will burden the purse of his parents, or that will lead to the rejection of valuable candidates whose powers for this reason or that are slow to develop. Yet the entrance examination for the medical profession ought to be of a much higher standard than it now is at many centres of medical education The smattering of knowledge which is all that the medical student need possess when he enters upon his professional career is of no real service to him and this is a situation with which the General Medical Council must soon deal

With regard to the lack of practical teaching of obstetric medicine and of anæsthetics at our medical schools we think that these reproaches cannot be so fairly urged to-day as they could have been five years ago The inspectors and visitors for the General Medical Council of the various final examinations of the United Kingdom have been careful to insist that the tests in obstetrics should be so far as possible practical, and as a result the student is now better equipped than formerly for one of the most important parts of his professional life It is not possible to insist upon a course of training for all medical students at a special hospital devoted to midwifery having regard to the amount that has to be got through in the five years of the curriculum, but short of this all care is, we believe, now taken to perfect the knowledge of the student in practical obstetrics It must be remembered also that attention to ordinary antiseptic principles means so much in the conduct of a normal labour that the general instruction obtained in the surgical wards furnishes a large part of the routine of midwifery practice. As regards a knowledge of anæsthetics, their administration is taught now at most hospitals and students have opportunities at many medical schools of producing anæsthesia under the immediate eye of an experienced anæsthetist. Mr. FRANKLIN has rightly urged the necessity of the medical student being familiar with these two important branches of his life-work, but we think that he has hardly appreciated how entirely his views are the views of those responsible for medical training.

The British Medical Association: The Address in Medicine.

WE may congratulate the British Medical Association on its selection of Dr. HENRY MAUDSLEY to deliver the Address in Medicine and likewise felicitate him on his choice of the subject of "Medicine, Present and Prospective." To review the present position of an advancing science and an applied art such as medicine and to indicate fruitful fields to cultivate in the future requires a catholicity of range, a depth of knowledge, and a position of disinterested detachment which it is given to few to possess. Fortunately, our profession owns in Dr. MAUDSLEY a hysician who is at once a philosopher and a man of proound and original thought, with the faculty (too rare owadays) of expressing his opinions in graceful yet ucid language. The address delivered by him is a model of its kind, affording material for careful conideration and ideas for future advancement; there is at times a vein of gentle satire, incisive but never unkind, which gives a piquancy to it. After enunciating the truism that error does not become truth because it is repeated thousands of times by many thousand persons, he suggests that "if a competent thinker constituting himself a sort of *advocatus diaboli* were to write a book entitled 'Medical Doubts,' setting forth reasons why some accepted truths may not after all be true, he would do a real service to medical science." In this we agree with Dr. MAUDSLEY and may express the wish that he will constitute himself the mentor and yield to medicine this needed service. "There is no darkness but ignorance," said the jester in *Twelfth Night*, so in science there is no stagnation like that due to the blind acceptance of time-honoured dogma.

The pace of medical progress was never so rapid as during the last 50 years says Dr. MAUDSLEY, and though the right of present congratulation is rather to surgery yet he is anxious lest the surgeon in his zeal to restore quickly the normal shall supplant instead of aid nature, and points out the mutual aid and instruction which surgery and medicine may and should afford to one another. He rightly deprecates the present tendency to multiply words, too often of barbarous construction, descriptive of operative procedures or diseased conditions as not only unpleasing but a positive hindrance to thought. The future of medicine lies in the prevention of disease or in the arrest of its early processes; at present too often the medical practitioner is hampered in these matters by the late stage at which he is summoned to intervene; early arrest, no less than prevention, is to be preferred to cure. In prevention there are two plain courses to be followed: the one by precautions to prevent those attacks which arise from without, whether in gross form or of microbic nature, and the other to obviate the predispositions to disease by fortifying the powers of resistance of the organism against these same inimical agencies. It is this second aspect of preventive medicine, until recently somewhat neglected, which forms the main theme of the Address in Medicine. The question is asked whether we might not with advantage study the effects of marriage unions of different tendencies and immunities as factors in increasing or lessening predisposition to diseases and in illustration inquiry is made as to what is the constitutional disposition, if any, most likely in breeding to diminish a tendency to cancer or insanity. When we find the answer to such questions we shall have an opportunity of enunciating and applying practically rules such as Mr. FRANCIS GALTON desires as the basis of his new science of eugenics. In this connexion Dr. MAUDSLEY is glad to note that the present position of medicine in relation to tuberculosis shows a wise recognition of the necessity of fortifying the body inwardly to resist infection—that is to say, to lessen vulnerability rather than to hope for the absolute elimination of exposure to infection. While recognising the value of sanatoriums, he regrets the want of sobriety in some medical statements on the popular platform whereby public opinion is misled into supposing that pulmonary tuberculosis is curable and is no longer to be regarded as a bar to matrimony. He asks, "Can we eliminate the predisposing influence of heredity?" And again, "Might not the ultimate cost to the commonwealth be greater were these persons [the 60,000 or so consumptives who die annually in England and Wales] to go on living and breeding in it?" He admits that the subject is a tender one and continues: "Human life is so precious nowadays in all its states—phthisical, insane, criminal, inebriate, and the like—that it is the pious duty of the social organism not, as the healthy bodily organism tries to do, to extinguish or extirpate a morbid element, but to absorb it into its system, growing sympathy being the vital principle of social growth," but he fears the ultimate issue of such morbid absorptions. Of course, as he points out, these matters are not the concern of medicine but of sociology or eugenics. None the less, we cannot but feel that here he is perhaps too pessimistic; we may hope that the present is but a phase—a mere stage on the road to the general improvement towards which all research is directed, when disease processes can be dealt with at an early stage and morbid tendencies repressed or eradicated, and these indeed are the methods which he himself advocates. At the same time it is a matter for the common sense of the nation in general to determine whether the reproductive capacities of the unfit shall in the interests of the race be prohibited.

Like H. D. THOREAU, the apostle of simplification, Dr. MAUDSLEY pleads for the observance of the simple salutary rules of life and for temperance in matters mental and emotional as well as physical. He refers to the rôle which chemistry and physics, especially the newer discoveries, are playing in the elucidation of many vital problems, of the importance of the complex by-products of vital processes as poisons when function is deranged, and of the toxins of extraneous organisms, such as bacteria, in producing disease processes. After pointing out how chemical research is steadily sapping the barrier between organic and inorganic nature and has now reached the very confines of life, he foresees that it is inevitable "that all divisions of science shall gradually be effaced, even that which metaphysics has fixed between bodily and mental life, the partitions being received as conveniences of thought, if all nature be one process of orderly evolution and the function of science be to find it out." He is of opinion that the artificial barrier set up by metaphysics between body and mind has been a hindrance in the past and he proceeds to show the absolute and essential unity of both and the importance of so regarding them whether from the physiological or the pathological point of view. "Mind works in every function of the body; a sound body is the foundation of a sound mind; and the lunatic is lunatic to his finger-tips," sums up his views in his own words. He further hopes just as increasing knowledge in other branches of biology leads to practical advances, so also that a more clear and just conception of the subtleties of the forces at work in mental action may lead to their scientific application to cure diseases of the body. He foresees that medical science will play a large part in the future improvement of the race and that the laws of mental breeding, yet to be discovered, will play a part in that improvement. It is a mistake to assume that moral qualities are not dependent upon physical constitution, and vice and sin require scientific inquiry and explanation if they are to be eradicated no less than poisons do. "If one thing is certain," says Dr. MAUDSLEY, "it is that wrongdoing—whether error, vice, or sin—is avenged on earth—not always, it is true, on the individual wrongdoer, but somehow, somewhere, on others bound together with him vitally in the social system."

◆

The British Medical Association: The Address in Surgery.

MR. C. J. BOND imparted a somewhat novel tone to the Address in Surgery by deviating from the lines which have become traditional. It has been the custom almost invariably for the orator to dwell upon the recent successes of surgery and to show the advances which have been made. Mr. BOND, however, took as his subject an interesting physiological question—that of the possibility of a retrograde current in mucous canals. Physiology is usually regarded as the handmaid of medicine and surgery, but in this case Mr. BOND claimed that surgery was helping to solve an important physiological problem. It has long been known that patients to whom has been administered a castor-oil enema claim to be able to taste the oil, and cases have even been recorded where the patient has vomited a small portion of a substance introduced into the rectum, though in some of these the possibility of malingering must be considered. The fæcal vomiting of intestinal obstruction is analogous and of this two explanations have been given. According to one the peristalsis of the bowel has been reversed, though any other evidence of such an occurrence is lacking, and according to the other theory there has been an upward central current reflected from the obstruction. The hydraulic possibility of this latter theory is not beyond doubt and it must be confessed that the true explanation is not yet forthcoming. Mr. BOND's observations deal, however, with less gross manifestations of a retrograde current in mucous canals, his experiments being made on the large intestine, the female generative tract, the upper intestinal, the urinary, and the respiratory tracts, and also the ducts of glands.

In nearly all these regions he has utilised cases in which fistulæ have formed, or been made, and he has introduced an insoluble coloured powder, indigo or carmine (carefully sterilised), into the lower aperture of the canal, and after an interval he has been able to demonstrate the presence of the pigments at the fistula. For instance, in a case of fistula after an excision of a portion of the sigmoid flexure for carcinoma Mr. BOND introduced some carmine into the rectum and within 24 hours the colouration of the carmine could be distinctly seen at the colectomy wound. In another case, where an operation for acute appendicitis with abscess resulted in the formation of a fistula communicating with the cæcum, indigo suppositories were introduced into the rectum. Three days later the particles of indigo were found in the discharge from the fistula. Still more surprising, however, is the fact that during those three days, while the particles of indigo were making their way slowly upwards along the colon, the patient took two aperients and free actions of the bowels occurred on all three days. In this case it is clear that the upward movement could not be due to any reversal of the peristalsis, for during the upward progress of the pigment there was an energetic peristalsis in the opposite direction. Even a marked narrowing of the bowel cannot stop this upward movement, for in one case there was apparently complete malignant obstruction high up in the rectum, yet indigo introduced in the anus showed itself at the colotomy wound within 24 hours. We must suppose that though complete obstruction to the passage of fæces was present, yet the occlusion was not absolute. Care was taken in all cases to prevent the direct transference of the pigment from the anus to the colotomy wound, so that we cannot deny that there was a slow upward movement of the indigo or carmine from the anus to the fistulous opening in the left or right groin. In considering the method by which this removal was effected we must bear in mind that as insoluble pigments were chosen it is impossible for the blood or lymph stream to be responsible for the ascent. It is not due to any capillary action; for in the dead bowel no upward movement occurs. Mr. BOND considers that any increase of peristalsis, as produced by an aperient, favours the upward current. This movement has been shown, also, to occur even in healthy bowel, unmodified by disease or operation, for a guinea-pig has been killed 48 hours after some indigo had been inserted in the rectum and the pigment was discovered high up in the colon.

Mr. BOND claims that the explanation of these phenomena is to be found in the presence of an upward mucous current close to the mucous membrane, capable of carrying minute particles with it. He does not suppose that this peripheral current is continuous but suggests that it may be intermittent and perhaps alternating with the downward peristalsis. Experiments have been made with particles of various sizes and Mr. BOND found that the particles of lycopodium powder were the largest that could be carried. Observations, essentially similar, were made on the upward passage of solid particles along the female generative tract. When indigo was placed just within the os uteri in cases of disease of the Fallopian tubes 24 hours before the operation for the removal of the diseased tube, in the vast majority of cases the pigment was found in the contents of the tube. The operation of cholecystostomy afforded many opportunities for observing the upward passage of pigment along the common cystic ducts, the indigo having been administered by the mouth. We need not detail the result of Mr. BOND'S observations on the urinary tract and the breast, although in these cases also very definite evidence of the upward passage of pigment particles was obtainable; for the particulars we must refer our readers to the paper itself which is published at p. 275 of our present issue. The practical importance of these numerous observations is obvious. If large solid particles like those of indigo and carmine can be carried from the anus to the cæcum, from the duodenum to the gall-bladder, from the external os uteri to the Fallopian tubes, from the nipple to the interior of the mammary gland, and from the bladder to the kidney, we may well conclude that the far more minute bacteria can also pass readily in the same direction, and thus we have an explanation of many infections hitherto inexplicable. In the case of the breast we can appreciate the especial importance of these observations, for the occurrence of all forms of microbic mastitis can be easily explained. And it is certain that Mr. BOND'S observations will impress on the surgeon more strongly than ever the danger of infection of many tracts by the introduction of micro-organisms into their outer openings. Other observers will repeat, confirm, and extend the experiments described in Mr. BOND'S address and it may well be that we are underrating the importance of this upward mucous current, now first described.

◆

The Proposed Amalgamation of London Medical Societies.

A TIME has come when it behoves every member of every kind of medical society in London to think carefully of his future as such a member. For representatives of his society will be called upon, presumably at no very distant date, to state that society's views as to the desirability of amalgamation with other societies. And these representatives will, we hope, be justified in feeling that the opinion which they express is the deliberate choice of, at any rate, the great majority of their fellow members. What that opinion will be we do not care to speculate, but we may candidly state our own warm sympathy with the scheme as it is suggested by the report of the executive committee, to the appointment of which we alluded recently,[1] and we may draw attention to a few of the arguments which ought to influence members of all the societies and their representatives. Every reform, no matter in what sphere of social or political life, entails difficulties and arouses resentments whether of a general or of a private nature. The wise man, however, is able to judge between his individual feelings and the general advantage, and to vote for that which enhances the one even if it at the same time rather sacrifices the other. It is some such wisdom that many of our readers will be called upon to exercise if they are asked to merge their own particular society into an institution comprising also all the sister bodies. Yet whatever be the particular society to which a man belongs, however dear its ancient traditions, however revered its surroundings, and however flourishing its financial state, we believe that its members will gain more by the apparent sacrifice that they may be called upon to make than they will by a conservatism which, if it keeps for them one or two comparatively small privileges, certainly robs both themselves and many members of less influential societies of the benefits that accrue from a great central institution. That a certain amount of sacrifice is involved in the proposed change is inevitable. A pleasing sense of individuality must be given up, but the individuality which tends to keep a special branch of medical study apart from all other branches should be lost with no regret. The sacrifice of money to which it is possible the richer bodies may be put is one that will not, we believe, influence their rulers when it is a question of helping to extend great benefits to the whole medical profession of the country. Moreover, as the report points out, the financial practicability of the scheme, and consequently the financial damage to be incurred in any direction, is uncertain until a definite statement is possible as to which societies will join the proposed Royal Society of Medicine.

Some of the societies again possess valuable libraries and may look with apprehension upon their removal from an old-established resting place. They will, however, be removed to one as safe and as dignified, only perhaps more frequented. There is no doubt that the accumulation under one roof of the several fine medical libraries, general and special, belonging to various London societies will be of the greatest service to workers in many branches of medicine and the sacrifice of duplicate copies, weighs as nothing against the advantages of one complete library of reference. The economy in the working staff that is derived from concentration of this kind needs no demonstration. This economy, moreover, is likely to remove from the harassed hands of honorary secretaries much labour that can be conveniently accomplished by the regular efforts of a paid official The report of the executive committee, which we publish on p. 310, seems to warrant the supposition that the new society would start upon a sound financial footing. For in supposing that about 4000 members of societies, other than the Royal Medical and Chirurgical Society, would become members at the rate of a guinea per annum, we do not think too high an estimate of the probable number has been made. Indeed, it seems pretty certain that so far as the individual member of any one society is concerned the new scheme gives nothing but advantage. It is only where a society as a corporate body is concerned that there can be any question of the gain in amalgamation. To most of the societies it will be a gain in prestige to form part of a Royal Society, and to all it will afford the satisfaction of an increased sphere of usefulness. That this would ensue from an amalgamation scheme we have no doubt at all and may point in illustration merely to one feature of the institution as proposed in the report of the executive committee. We allude to the monthly publication of the proceedings. Such a periodical would be of the highest value to every medical man who aims at keeping his knowledge up to date in all its branches. Moreover, such a publication is impossible except as coming from a body of the nature of the proposed Royal Society. We cannot be accused of partiality when we refer to the value of a periodical of the nature suggested, for without a doubt it would seriously affect the interest of certain portions of our own pages. The monthly periodical would offer a boon not to its readers only but perhaps even more markedly to the authors of the papers. At the present time so long a period elapses between the evening when a paper is read and the date at which it appears in the Transactions that interest has often diminished even if fresh and contradictory material has not discounted the original value of the writing. Moreover, there would be a certain authoritative value about the publications of the Royal Society of Medicine and in the case of papers selected for publication in the yearly Transactions this would be very great. In fact, the selection of the papers would, we imagine, form one of the most formidable of the difficulties confronting the executive of the new body. No doubt each section would be represented on the selection committee for the Transactions, but even then it is easy to imagine heart-burnings over non-selected papers with subsequent suggestions th the sectional representation was inadequate or inefficient.

---

[1] THE LANCET, April 15th, 1905, p. 1003.

All such questions as these, however, are matters of detail and in no way really affect the broad principles of the scheme which alone the report pretends to put forth. Both the ideas represented and the manner in which they are put forward appear to us to reflect great credit upon the executive committee and in particular upon its secretaries whose labours must have been anything but light. One detail over which there will doubtless be much difference of opinion is the title of the new amalgamated society of medicine. In these columns we have occasionally spoken of the future body as the Royal Society of Medicine and this is one of the suggested titles. We have chosen it by way of silent protest against the suggested alternative. "Academy" is, we think, a word carefully to be excluded from the name. Either it conveys the impression of a selective exclusiveness which cannot appertain to any body of the nature of the proposed amalgamated society or it reminds us of an institution that exists to foster art and is largely notorious for neglecting even the best exponents of art unless they conform to an uninspiring conventionality.

DONATIONS AND BEQUESTS.—Mr. Philip H. Vaughan has given £5000 towards the £50,000 which the committee of the Bristol Royal Infirmary is raising.—Sir Massey Lopes, Bart., has increased his endowment to the Plymouth Public Dispensary by £500, making his endowment now £2500.

Annotations.

"Ne quid nimis."

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE British Association for the Advancement of Science, as all our readers know, will this year hold its meeting in South Africa, the main proceedings being divided between Cape Town and Johannesburg, whilst lectures and addresses will be delivered at various other towns. This is the third time only since the foundation of the society in 1831 that it has met outside the United Kingdom, Canada having been chosen as the place of meeting in 1884 and in 1897. The inaugural meeting this year will take place at Cape Town on August 15th and on the following day Professor G. H. Darwin will deliver the first half of his presidential address, the second portion of which he will deliver at Johannesburg on August 30th. He proposes to discuss the general principles involved in theories of evolution with special reference to the world of inanimate matter. In addition to Cape Town and Johannesburg the itinerary of the association includes Durban, Pietermaritzburg (where Colonel David Bruce, R.A.M.C., will deliver a lecture on sleeping sickness), Pretoria (where Professor A. E. Shipley, the University Lecturer at Cambridge on Advanced Morphology of Invertebrates, will discuss fly-borne diseases and malaria), Bloemfontein, Kimberley, and Bulawayo. The matters to be discussed are divided into 11 sections but Sections D and I, which deal respectively with Zoology and Physiology, will naturally appeal most closely to the medical members. In Section D Mr. L. Doncaster will discuss recent work in Gametogenesis and its Bearing on the Theories of Heredity. Colonel Bruce, R.A.M.C., who is president of Section I, will take for his subject the Advance in our Knowledge of the Causation and Prevention of Stock Diseases in South Africa during the last Ten Years, such as rinderpest, pleuropneumonia, and horse sickness. Dr. Theiler and Dr. G. Turner, medical officer of health of the Transvaal, will also read papers on the same subjects. Professor G. Sims Woodhead will discuss the subject of Dysentery and other papers are announced to be read by Dr. D. Ferrier, Dr. D. Macaulay, and Dr. Louis G. Irvine. Other medical men who may read papers or open discussions in this section are Sir Lauder Brunton, Professor Mackendrick, Dr. A. J. Gregory, Dr. A. Jasper Anderson, Professor Bohr, Dr. J. A. Mitchell, Dr. B. S. Black, Mr. John Maberly, Dr. A. Edington, and Dr. W. Robertson. In connexion with this meeting the proprietors of *Knowledge* have issued a special number of their journal, which contains a biographical notice of the President of the British Association with portrait, a sketch of the origin and progress of the British Association, with portraits of the presidents of sections, a route map showing the various places to be visited by members of the Association, and articles on the Races of South Africa, the Diamond Mines of South Africa, South African Natural History, the Extinct Reptile Fauna of South Africa, the Zambesi and its Sights, and many other features of interest both to those who are fortunate enough to be able to visit South Africa and to those who are compelled to follow the proceedings of the Association as reported in the scientific journals at home.

LONGEVITY.

THE question how shall a man live to be 100 years old has been asked by many generations of men. Anciently the belief in extreme longevity was based on Scriptural authority or on the analogy of certain folk-lore traditions according to which some animals, such as crows and deer attain to immense ages. In the Middle Ages, in fact, the stag was supposed to be capable of living 1000 years, and it required all the acumen of Sir Thomas Browne in his "Popular Errors" to show that deer are not likely to be long-lived and that, as a matter of fact, some 30 to 36 years probably mark the span of their existence. Sir Thomas Browne argued that there is a certain ratio between the years of growth and those of decline, and at a later date Flourens worked this theory out and concluded that animals have the capacity, as a general rule, of living five times longer than their growing period. "Assuming this," wrote Dr. Protheroe Smith in 1885, "as regards man, on an average, to be 21 years (and excluding accidents, diseases of heredity, and unhealthy and unfavourable surroundings and habits), our term of life should be at least 100 years." The growth of what Dr. Protheroe Smith called spino-pelvic deformity was held by him to shorten life. Accordingly he proposed to keep the pelvis in its "natural oblique plane" by means of a "pelvic band," by which "the pelvic plane is easily restored to the normal angle of 140 degrees" and the viscera are kept in their proper places. It is the displacement of the viscera through loss of the spino-pelvic curve in old age which produces derangement of "the pelvic and the renal organs." These often "give out first in the final struggle to avert the termination of life." The "pelvic band," by keeping everything in place, keeps the human frame youthful despite the advance of years. Dr. Protheroe Smith, in fact, was for the attainment of longevity by the use of an appliance. His was the anatomical view. Sir James Crichton-Browne, on the other hand, is reported to have said recently that improved sanitation and a quiet life would conduce most to the attainment of a measure of existence far exceeding the 70 years spoken of by Moses in Psalm 90. In this view he follows Sir James Sinclair who wrote on longevity in 1807 and held that it depended chiefly on regimen and favourable external conditions.

THE IDEAL MILK FARM AND THE PRODUCTION OF MEDICALLY CERTIFIED MILK.

IN an interesting paper read at the recent meeting of the Royal Institute of Public Health Mr. H. Reginald Rhodes described the method by which medically certified milk is produced in the United States and he also said that if he was encouraged he was prepared to develop and to advance the principle of this method in England. Medically certified farms have been established in the State of New York during the last few years for the express purpose of producing milk of the very highest attainable purity by means of a system of rigorous cleanliness and precaution against all possible sources of contamination through the cows, the employés, or the utensils. Everything is sterilised except the milk which is produced as nearly as possible under aseptic conditions. At the Woodlawn farm the dairy buildings consist of two main blocks: (1) the living or feeding cowhouse; and (2) the washing and cleaning shed and the milking and bottling shed. The day's work commences quite early in the morning when each cow is led singly and in turn from the stable into the washing and cleaning shed. Here it is washed antiseptically with sponges and brushes and dried with sterilised towels. The cow is then taken to the milking shed. The milkers are required to wash themselves thoroughly in a bath-room provided for the purpose and to wear clean linen clothes which are frequently washed and sterilised twice daily. The milk is passed directly from the milking stable through a "drum" in the bottling room and is bottled immediately. All bottles and utensils are kept rigidly clean and are sterilised before and after use. In the bottling room troughs of water are kept at a very low temperature by means of pipes from the refrigerator in the building. The bottles of milk are kept quite cold after filling and sealing. The latter is done by means of a special pasteboard cap covered by a capsule furnished by the medical inspector. The bottles in the cooling troughs are subsequently packed in ice in cases of one dozen each and distributed. Special attention is paid to the conditions under which the cow is kept and stalled. There are no mangers or feeding troughs. All fodder is eaten from a concrete floor and once or twice each day the whole surface is swept with water from a hose pipe. The walls are paint-enamelled and are washed regularly. The cows are not allowed to graze on the farm land but the buildings in which they are kept and in which the various operations are carried on are well ventilated and well lighted. The system is obviously based on sound hygienic principles and its promoters candidly admit what must be equally obvious that its adoption raises the cost of milk production. But the question of cost may be dismissed when the gain to human health and life which would result were the system made universal is considered. The experience in New York is that the demand for medically certified milk is greater than the supply, though it costs about 1s. per quart. In England certain items of expense, however, could be reduced, as, for example, that of labour, and the price of the milk would be correspondingly less. It is urged that by insisting on the cleanly methods outlined the bacteria in the milk are diminished from 5,000,000 in ordinary milk to some hundreds only per cubic centimetre in the milk produced under hygienic precautions, and this is a strong argument for the abandonment of methods which only too clearly are not in accordance with the requirements of public health. It is highly desirable that milk as a factor in disease and mortality should be as far as possible eliminated.

DEMENTIA PRÆCOX.

AT the meeting of the American Neurological Association, which was held in September, 1904, Dr. B. Sachs opened a discussion on this condition and his paper has been published in the *Journal of Nervous and Mental Disease* for June, 1905. Dr. Sachs observes that the definition of dementia præcox as given in the writings of Kraepelin and his followers is broad enough to embrace almost every form of psychic derangement in the young. There is consequently a great temptation to diagnose a vast majority of the cases of mental disease in youthful persons as cases of that disorder. If this were justifiable the age of the individual would of itself postulate the diagnosis. Dr. Sachs enters a strong protest against these tendencies. The only feature which the forms of the disease distinguished by Kraepelin have in common is a supposed termination in dementia, but even this writer states that in 17 per cent. dementia never sets in and that in others there are long periods of remission during which the patient enjoys perfect health. In former days, when the insanities of adolescence were diagnosed under various headings, we were content to state that in certain circumstances, such as frequent repetition of the attack or presence of distinct hereditary taint, dementia might ensue. Dr. Sachs asks whether there is any gain in pushing the idea of dementia into the foreground and then setting the seal of ultimate mental deterioration upon these cases. He considers that the term "dementia præcox" implies a far too grave prognosis in many of the cases. A case is detailed in which this disorder was diagnosed by a well-known alienist but the patient regained almost completely his mental health and his subsequent history showed that it was a distinct injustice to make a diagnosis of dementia. In a second case which occurred before the spread of Kraepelin's doctrine but in which, had the patient been examined at the present day, the diagnosis of dementia præcox would no doubt have been insisted on, a complete recovery took place, the individual attaining a prominent position. The limits of the paper preclude the record of further cases which show that a process of apparently progressive mental deterioration may be arrested and that the patient may regain full mental vigour. Whilst protesting against the too extensive application of the term "dementia præcox" Dr. Sachs is willing to admit that our knowledge of the youthful insanities has been considerably advanced by its introduction.

THE STANDARDISATION AND STORAGE OF DRUGS.

AT the opening of the annual meeting of the British Pharmaceutical Conference at Brighton, last week, the President, Mr. W. A. H. Naylor, F.I.C., chose as the subjects of his address the Standardisation and Storage of Drugs. The object of standardisation is, Mr. Naylor said, to secure uniformity of strength, more especially in respect of medicinal activity. The required standard may have a physical, chemical, or physiological basis and may have reference to one or more definite principles or to a mixture of undefined substances. It should be the aim of the pharmacist to produce preparations that will fully represent the therapeutic activity of the drugs operated on, except in cases where it is desired to obtain the medicinal effects of certain definite principles to the exclusion of others. As an illustration, a preparation of opium might be required free from narcotine. In the case of drugs containing several active constituents it may in the future be desirable to apply the process of standardisation to certain principles hitherto disregarded which modify the therapeutic action. The pharmacologist may be depended on to point the way and, with the assistance of workers skilled in pharmaceutical research, to overcome the present tendency to produce a preparation and to standardise it on the basis of one particular principle, regardless of other constituents which may, directly or indirectly, be of therapeutic value. For instance, according to present knowledge the chief active constituent of scopolia and henbane is hyoscyamine. If a tincture of each be prepared so as to contain the same percentage of alkaloid it is doubtful whether, from a therapeutic point of view, it is a matter of indifference which of them is selected for use. The fact that the physician finds it advantageous to administer henbane at one time and scopolia at others suggests that these drugs do not give identical results. This may be taken as *primâ-facie* evidence that other constituents are present which modify the action of the hyoscyamine. Mr. Naylor devoted some attention to a number of potent drugs for which there are at present no satisfactory methods of standardisation, including Calabar bean, hemlock, henbane, jaborandi, stramonium, and strophanthus. The most recent investigations of Calabar bean point to the presence of three bases, of which eserine is supposed to represent the therapeutic properties on which the physician depends when he prescribes the official extract. In the case of hemlock the medicinal properties of the drug may be due to one or more of the following constituents, coniine, ethyl piperidine, methyl coniine, conhydrine and pseudo-conhydrine. From the experiments of Findlay we may conclude that the fluid extract of hemlock and the mixed alkaloids obtained from the drug act physiologically in a manner analogous to pure coniine. Hence the determination of total alkaloids in preparations of hemlock would probably serve the purpose. The standardisation of preparations of henbane is complicated by the fact that in addition to hyoscyamine the drug contains hyoscine, which is readily changed into atroscine (optically inactive scopolamine). It is not known whether hyoscine and atroscine have the same physiological value, hence it is desirable that care should be taken to prevent the change as far as possible during the manufacture of preparations of henbane. Jaborandi affords another problem in standardisation, as this drug contains at least two alkaloids, pilocarpine and isopilocarpine. Professor Marshall has shown that while these alkaloids produce similar effects on the secretory activity of the sweat and salivary glands, the former is the more powerful. It would seem advisable to base a method of standardisation of jaborandi on the amount of pilocarpine which it contains. The standardisation of stramonium on the basis of the mixed alkaloids would scarcely be justified in the absence of precise information as to the physiological value of the several alkaloids. A preliminary announcement has just been made by Professor Ernst Schmidt of Marburg that the only mydriatic alkaloid present in stramonium is hyoscyamine, so that it may be possible in the near future to fix a definite standard for this useful drug Perhaps there is no drug that shows greater variations in the strength of its preparations than does strophanthus There is little doubt that its usefulness in affections of the heart is due to the glucosidal principle first isolated by Fraser from *strophanthus Kombé* and named strophanthin. But different species of strophanthus appear to yield glucosides which vary in their degree of toxicity, chemical constitution, and physical characters. To add to the confusion the seeds that reach this country are the mixed products of several species of strophanthus and they resemble each other so closely that they cannot be distinguished macroscopically. Fortunately, one species, *strophanthus gratus*, is readily distinguished by inspection from all other African species and contains a crystalline strophanthin which, according to Thoms, is identical with Arnaud's ouabain. A process for standardising strophanthus may therefore be regarded as within sight. Speaking of the storage of galenical preparations Mr. Naylor drew attention to the liability to loss of active principles by chemical change or precipitation on keeping. In his experience varying conditions of storage produce changes in galenical preparations. Even under the same conditions of storage they are not equally affected. The preparations of belladonna and nux vomica appear to be the most stable, those of cinchona less so, and the liquid extract of ipecacuanha the least of all, the loss of strength in each case being largely due to precipitation. Pharmacists, therefore, cannot bestow too much thought and care upon the storage of important preparations which, even when kept under the most favourable conditions, are not free from liability to a reduction in strength and consequently to impairment of their medicinal value.

THE INTERNATIONAL SOCIETY OF SURGERY.

AS we announced last week the first Congress of the International Society of Surgery will be held in Brussels in September under the patronage of His Majesty the King of the Belgians. The congress will be in session from Monday, Sept. 18th, to the following Saturday inclusive, under the presidency of Dr. Theodor Kocher, professor of surgery in the University of Bern The morning of each day will be arranged for visits to hospitals and clinics, for the exhibition and examination of patients, and for other matters of interest connected with the congress as well as with the city of Brussels. The afternoons will, so far as possible, be reserved for the consideration of the subjects selected for discussion. These are as follows:— 1. The Value of the Examination of the Blood in Surgery. 2. The Treatment of Prostatic Hypertrophy. 3. Surgical Intervention in Non-cancerous Diseases of the Stomach. 4. Treatment of Articular Tuberculosis. 5. The Treatment of Peritonitis. 6. The Diagnosis of Surgical Diseases of the

Kidney. Other communications of a practical nature (of which due notice should be given as well as the time they will occupy), including the presentation of patients, specimens, and surgical instruments and appliances, may be made. Messrs. Thos. Cook and Son, Ludgate-circus, London, E.C., have been asked to make suitable arrangements for the convenience of members of the profession going to Brussels from Great Britain. Facilities for a visit to the Liége Exhibition might be included in these arrangements. All information in regard to travelling may be obtained from Messrs. Cook but inquiries about hotel and lodging accommodation should be addressed to the secretary-general at Brussels. Further information can be obtained from the secretary-general, Dr. Depage, 75, Avenue Louise, Brussels, or from Mr. Reginald Harrison, 6, Lower Berkeley-street, London, W., delegate for Great Britain.

INTERNATIONAL LABORATORY OF PHYSIOLOGY.

IT may interest some of our readers to know that a laboratory with a hostel has been established at Col d'Olen as an adjunct to the International Laboratory of Physiology on Monte Rosa. This (lower) laboratory is mainly intended for biological research but it is understood that provision has also been made for the study of terrestrial physics and meteorology. The Royal Society has the permanent nomination to two posts, each of which includes a living room in the hostel, a bench in the laboratory, and the use of apparatus, but the expenses of living and of special researches must be borne by the investigators. The laboratory is especially connected with the University of Turin but is under the immediate direction of a committee. Applications for nominations to the two posts referred to above may be addressed to the secretaries of the Royal Society, Burlington House, London, W.

CONTINENTAL TRAVEL AND ITS DANGERS.

"THERE is in Italy," writes an Italian correspondent, "a national association to encourage the influx of foreigners (*Un' Associazione Nazionale per l'Incremento del Forestiere*) and its directors, among whom are Members of Parliament, bankers, and other leading citizens, have recently been conferring with the Minister of Foreign Affairs, Signor Tittoni, as to the best means of obviating what is becoming a deterrent to the tourist or 'desirable visitor'—to wit, the robberies practised on the main routes by the 'ladro cosmopolita' (the cosmopolitan thief) who appears to grow in numbers and dexterity with the increase of the travelling public. His Excellency gave the customary assurances that the subject would have his immediate attention while he would redouble the vigilance of Italian representatives abroad and, by their means, enlist the coöperation of the diplomatic *personnel* of other countries for the suppression of an evil which was becoming more or less general. For some time, moreover, there has been concerted action between the heads of the police in the chief continental States; and the experiences, such, at least, as have been made public, of these functionaries and their agents are full of warning to the world so soon to be 'on the wing.' Organisation, with division of labour, has been carried by the 'ladro cosmopolita' to something very near perfection until he finds himself 'at home,' with confederates always available, from Nijni-Novgorod to Palermo, from Ostend to Seville. Always well dressed, with no lack of money, he affects the 'train de luxe,' and, most of all, the 'corridor carriage,' with the dining saloon and the sleeping compartment. There he 'takes stock' of his victim and (if, indeed, he has not relieved him of handbag or purse already) follows him to the hotel or *pension* at which he alights. There he is generally to be found in the best apartments and at *table d'hôte* or in winter garden or reading room; he is as 'correct in his conduct as in his dress, speaking more than one language fluently and volunteering help or advice often acceptable. Naples, Rome, Florence, Milan, Venice have all been favoured with his society of late, till scarcely a week passes without their journals putting on record an 'incident' of which the following is a typical example. Having secured a bedroom contiguous to that of his intended 'prey' he begins operations by perforating the wall near where his unconscious neighbour lays his head (instruments for the purpose he possesses in abundance) and at night through the aperture thus made he passes a cannula, long and fine, through which he anæsthetises the sleeper, generally with chloroform! He then forces the door, always with instruments perfectly adapted to the purpose, and at his leisure helps himself to whatever he wants from valise, handbag, or exposed purse, or jewellery, and decamps in the early morning in time for the 'through express.' A Florentine journal of the day now passing (July 18th) gives a yet more dramatic 'object lesson' in the methods of the 'ladro cosmopolita.' When he cannot get accommodated next to his intended victim he finds means during the day of 'introducing' himself into the said victim's room; he gently undoes the fixings of the lock and, again at night, he brings into play the other resources of his 'profession'—the 'maschera cloroformizzata' (the mask with the chloroform), the eel-skin loaded with small shot wherewith to stun the victim by a sudden blow; nay, the finely pointed stiletto with which to reach the heart in a twinkling, should resistance be offered. Landlords, particularly on the French or Italian Riviera, are now familiar enough with this type of 'ladro' to give him a special name—'topo d'albergo' (hotel rat) being the title he is known by in Italy. That he should be on the increase, while it testifies to the growing yield of victims, should also intensify the vigilance of the continental Governments in the course now taken by the Italian Foreign Minister. Luggage robberies, which ought in Italy at least, to be minimised by the transfer of the railways to Government control with a better manned and better paid *personnel*, have hitherto been a not inappreciable deterrent to the 'influx of foreigners.' On the other hand, the improved appointments, sanitary and other, mainly due to the 'requirements' of the English-speaking world, in hotels and *pensions* are now a distinct inducement to the visitor from abroad in search of distraction or health. It is high time that, with these reforms *in esse* or *in posse*, another should be made by the suppression of the 'ladro cosmopolita,' so as to convince the travelling world that if crime can keep pace with civilisation the latter is not without 'resources for the correction of its sinister developments.'"

THE EPIDEMIC OF ICE-CREAM POISONING AT BIRMINGHAM.

Dr. John Robertson, the medical officer of health of Birmingham, presented to the members of the Birmingham city council his report on the recent epidemic of ice-cream poisoning. In all there were 52 cases of illness. One patient was an adult 46 years of age, one 20, one 18, one 17, and the others under 14. The interval between the purchasing of the ice-cream and the onset of the illness varied from half an hour to eight and a half hours and all the patients complained of pain in the stomach and vomiting. Diarrhœa and collapse were symptoms in the majority of the cases. The chemical analysis disclosed none of the ordinary poisons. The bacteriological examination showed that it contained a poison and that in certain cases it was capable of causing inflammation and death in guinea-pigs. The poisonous property of the ice-cream was due to the presence of a bacillus or bacilli belonging to the colon group. The bacteriological analysis was made by Professor R. F. C. Leith. It appears from the report that about 250 people purchased the ice-cream. Dr. Robertson states that the ice-cream was made amid very insanitary surroundings and in close proximity to three water-closets which were in a very filthy state. He conjectures that excremental organisms had been blown into one of the buckets of ice-cream while it was in a warm condition and that rapid multiplication of the organisms took place. The condition of the premises in which this ice-cream was manufactured was not, Dr. Robertson concludes, worse than that of many other premises where ice-cream and other foods were stored or manufactured in Birmingham, so that there was a possibility of similar outbreaks occurring on other occasions. It is to be hoped that some prompt measures will be taken by the health authorities of Birmingham to prevent further outbreaks and that other local authorities will keep a strict watch upon the manufacturers of this dangerous article.

THE CHAIR OF MIDWIFERY IN THE UNIVERSITY OF EDINBURGH.

THE University of Edinburgh will shortly proceed to the election of a Professor of Midwifery in room of Professor A. R. Simpson whose resignation of the chair has been accepted as from August 31st next. A Lectureship in Gynæcology is also to be instituted and candidates for the chair of Midwifery will have to agree on an adjustment of the several duties of the professor and lecturer under the direction of the University authorities. Further particulars may be obtained on application to the secretary of the University Court, Mr. R. Herbert Johnston, W.S., with whom each candidate for the chair is requested to lodge, not later than Friday, Sept. 15th next, eight copies of his application and eight copies of any testimonials which he may desire to submit. One copy of the application should be signed. The secretary's address is 4, Albyn-place, Edinburgh.

THE STERILISATION OF SO-CALLED DEGENERATES.

MEDICAL officers of asylums so rarely succeed in securing from the community at large that degree of recognition which their work merits that to find a superintendent's report appearing in the public press is a circumstance sufficiently remarkable to be worthy of record. The *Gloucester Journal* of July 15th devotes three and a half columns to the reproduction *in extenso* of the last annual report upon the Gloucester County Lunatic Asylums by Mr. F. H. Craddock and this fact may be regarded as evidence that the general public is at last beginning to recognise the importance of the social problem which insanity presents. Mr. Craddock's views, as interpolated among the statistics which are customary in publications of this class, though not presenting any special novelty for the medical reader, are calculated to arrest the attention of the laity and cannot fail to prove illuminative. After admitting "the inability of any attempts to cure insanity in the present state of our medical knowledge," Mr. Craddock suggests that there is only one way of dealing with this question—viz., "by rendering it physically impossible for those affected (whether more or less deeply) with the taint of insanity to reproduce their species." Approval is expressed of the sentiment that prohibition is "useless without the bistoury" and the sterilisation of degenerates on the lines laid down more particularly by Dr. R. R. Rentoul is advocated. We are so completely in sympathy with Mr. Craddock's aims that we are loth to criticise unfavourably the methods of accomplishing them to which he gives support but we are constrained to wonder whether the upholders of sterilisation have a clear conception of the magnitude of the departure from the current conventions of society which they propose. Considering the immense difficulty of obtaining even such legal powers as would enable the community to supervise and to control its degenerate members, there does not seem the slightest probability that any scheme of asexualisation will fall within the sphere of practical politics. Accepting Dr. Rentoul's quoted estimate that the proportion of mental degenerates is 1 in 50 and of the "physically diseased and undeveloped" 1 in 5 of the total population, it would appear that there is hardly a family in this country which would not have to make a sacrifice of its most cherished instincts of humanity. We believe that a certain physician of Kansas achieved some considerable share of unpopularity by performing castration on 58 boys, but it does not appear that he obtained results which simple detention would not have supplied equally well, and, indeed, it is probable that the procedure of sterilisation would only be practicable in cases where, owing to the absence of opposition on the part of friends, permanent detention would present no difficulty.

HEART-BLOCK IN MAMMALS AND STOKES-ADAMS DISEASE.

IN the *Johns Hopkins Hospital Bulletin* for June Dr. Joseph Erlanger has published some interesting observations on the phenomenon termed by physiologists "heart-block," which throw light on the rare and curious affection known as Stokes-Adams disease (persistent bradycardia with epileptiform fits). In studying a case of this disease under the care of Professor W. Osler he found that the disturbances in the circulation were obviously due to heart-block. When the block was complete the auricles responded normally to influences exerted on the heart through its extrinsic nerves, but the rate of pulsation of the ventricles seemed to be uninfluenced by changes in posture, by atropine, or by moderate exercise. However, the rate was increased by more severe exercise. On the other hand, when the block was partial the ventricles, as well as the auricles, responded normally within certain limits to extrinsic influences. During the attacks of unconsciousness the interval between the beats of the ventricle was as long as 12 *seconds*. These observations led Dr. Erlanger to study heart-block in mammals without destroying all the tissue in a cross section of the heart. He found that in the dog this could be done by clamping the limited region in which lies the only muscular connexion between the auricles and ventricles, the auriculo-ventricular bundle of His. When the clamp was placed in this position the heart continued to beat with undisturbed rhythm but when the arms of the clamp were cautiously screwed together the normal sequence of the auricular and ventricular beats gave place to a partial block in which the beats of the auricles were to those of the ventricles as 2 to 1. With further clamping a 3 to 1 rhythm was sometimes established and this usually passed into a complete block in which the beats of the ventricles were independent of the beats of the auricles. These changes occurred in reverse order when the clamp was unscrewed. As a rule the changes of rhythm occurred suddenly, that is, without preliminary stoppage of the ventricle. In two experiments on tightening the clamp the normal sequence gave place to complete block without passing through intermediate stages; the ventricular rate was markedly slowed and the blood pressure fell to a very low level. In one case the interval between two ventricular contractions was 21 seconds. The ventricular rate and the blood pressure then gradually increased. With each change of rhythm the blood pressure was much affected, falling with the fall of ventricular rate and rising with its increase. But even in complete block a fair pressure might be maintained. With partial block both auricle and ventricle might be inhibited by stimulation of the vagus as easily as under normal conditions. But when the block was complete no diminution or only slight diminution of the rate of the ventricle resulted from stimulation of the vagus. The auricles reacted normally to vagus stimulation. Section of both vagi had little or no influence on the rate of the ventricular beat when the block was complete. But stimulation of the accelerator nerve usually increased the rate of the ventricle. This was sometimes as great proportionally as in normal conditions. The reaction of the auricles to stimulation of the accelerator nerve was not influenced by the block. The analogies between heart block in the dog and Stokes-Adams disease are thus obvious. Dr. Erlanger therefore concludes that the situation of the lesion must be the same in both conditions.

OVERLYING AN INFANT PUNISHED AS MANSLAUGHTER.

At the recent Chester assizes, on July 19th, Mr. Justice Phillimore sentenced a woman, aged 31 years, to 21 months' imprisonment with hard labour. It was given in evidence that 11 days after her confinement, at Birkenhead, she insisted on taking her child, who was thoroughly healthy, to bed with her when she was in a drunken state; she slept heavily and overlay and suffocated the infant. The jury found her guilty of the manslaughter of her babe by an act of gross and culpable neglect. Many coroners have tried to secure such a verdict in similar cases of alcoholic infanticide but they find it very difficult sufficiently to persuade the inquest juries sitting upon such unnatural deaths and even where these juries have agreed to a verdict of manslaughter when the case comes before the sessions or the assizes the grand jury commonly finds "No true bill," for public opinion does not yet consider the massacre of the innocents concerned as a criminal offence capable of proof.

THE ADDITIONS TO THE SCHEDULE OF POISONS.

As announced in THE LANCET recently[1] the Council of the Pharmaceutical Society has recommended certain additions to the schedule of poisons. These suggestions have been considered by the Privy Council with the result, as announced in the *London Gazette* of July 18th, that the majority of the substances named have been added to the schedule. Of these, cocaine and its salts, picrotoxin, preparations of cocaine, digitalis and its preparations, mercuric iodide, mercuric sulphocyanide, and strophanthus and its preparations are now deemed to be poisons within the meaning of the Pharmacy Act, 1868, while cocaine and its salts and picrotoxin are deemed to be poisons in the first part of the Schedule A of the same Act. The substances not approved by the Privy Council as additions to the schedule are acetanilide, soluble salts of oxalic acid, and sulphonal. These are quite ignored by the Privy Council, in spite of the fact that the Departmental Committee on Poisons unanimously recommended the addition of these substances to the schedule. It may be that the authorities at Whitehall have listened favourably to the objections advanced by interested persons to the inclusion of these substances in the schedule. Be that as it may, the responsibility will rest with the Privy Council if further fatalities occur through the unrestricted sale of these drugs. The Council of the Pharmaceutical Society has exercised its statutory functions in the matter and has performed a public duty. This is not the first time that a Government department in its wisdom has over-ridden the representations of departmental committees and other technical advisers.

THE following are among the recent amounts received at the Mansion House in behalf of the Metropolitan Hospital Sunday Fund:—St. Mary Abbots parish, Kensington, £758 13*s.* 11*d.*—viz., St. Mary Abbots, £540 12*s.* 3*d.*; Christ Church, £100 16*s.* 4*d.*; and St. Paul's, Vicarage Gate, £117 5*s.* 4*d.*; St. Nicholas parish church, Chislehurst, with St. John the Baptist, £265; St. John, Paddington, £195; St. Paul, Avenue-road, £145; St. Paul, Beckenham, £140; and Lincoln's Inn Chapel, £105. The total now exceeds £61,000.

DR. A. C. Houston has been appointed Director of Water Examinations, Metropolitan Water Board, at a salary of £1000 per annum.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE QUATER-CENTENARY CELEBRATIONS.

THE Royal College of Surgeons of Edinburgh began the celebration of its quater-centenary on Wednesday evening, July 19th, by a formal reception of its guests at its home in Surgeons' Hall. The more public part of the celebrations began on Thursday morning and were continued without much interval until early on Saturday forenoon. The weather fortunately was very fine and contributed not a little to the success of the series of entertainments organised in honour of the occasion.

The opening public ceremony was a service in the old Cathedral of St. Giles. The College authorities had fortunately obtained permission to use part of the hall of Parliament House as a meeting place and there their distinguished visitors, representatives of many local bodies, of learned societies, and of the medical press met, and being carefully marshalled walked in procession across Parliament House-square to the west entrance of the cathedral from which point, passing up the central aisle, they reached their seats in the choir. Academic costume or uniform was worn. An elaborate attention to detail, due to the younger Fellows of the College under the direction of Mr. J. W. Dowden, the special secretary for the occasion, characterised all the functions and gave a smoothness and finish to them worthy of the masters of the ancient craft and pleasant to those who had the privilege of participating in them. The service in the cathedral consisted of a specially printed liturgy, the prayers having particular bearing upon the occasion. They were read by the Very Rev. Dr. Cameron Lees, Minister of St. Giles and Dean of the Chapel Royal of Scotland. The sermon was preached by the Rev. Dr. William P. Paterson, Professor of Divinity in the University. He took as his text St. John ix. 1–3: "And as Jesus passed by, he saw a man which was blind from his birth. And his disciples asked him, saying, Master, who did sin, this man, or his parents, that he was born blind? Jesus answered, Neither hath this man sinned, nor his parents: but that the works of God should be made manifest in him." The preacher at the outset referred to the old connexion between the Incorporation of Barber-Surgeons and St. Giles's, the Incorporation in the early days maintaining an altar in St. Giles's dedicated to God and to their patron saint St. Mungo. He thought that apart from this there was sufficient reason that the intimate relations between the healing art and the Christian Church should be prominently recognised at such a celebration as the present. It was true, he said, that at certain periods the Church attempted to obstruct the march of science along particular lines and retarded to some extent the development of a rational system of medicine, but as an offset to that it was to be remembered that amid the shocks and losses of mediæval times it was the Church which was the chief custodian of the scientific legacy from antiquity which saved the world from intellectual bankruptcy, while the enthusiasm of humanity which had supplied the moral dynamic of the medical profession in the modern western world had been chiefly engendered by the religion which adored in a good physician God manifest in the flesh and which proclaimed the infinite value of every human being as made in the image of the Eternal God. The preacher then proceeded to examine the problem of human suffering and to contrast the old-world idea that it was to be explained on a penal principle with the Christian view laid down in the text, that a world of disease was a world of divine opportunity. The remarkable saying of Christ found its most obvious illustration in the rise and progress of medicine and surgery. A grim necessity, as Hippocrates put it, was the mother of the healing art. The universal and unceasing distress was an imperious summons to thought and action and in responding to it the human mind found a field in which it discovered and matured its latent powers and also entered upon a course of brilliant and beneficent discovery. The preacher at considerable length then traced the development of the healing art and showed how pure science became in the first place a by-product of practical medicine until knowledge came to be sought for its own sake.

---

[1] THE LANCET, April 15th, 1905, p. 1013.

After the service in St. Giles's Cathedral a luncheon was given by the Lord Provost, magistrates, and town council in the City Chambers. The company numbered about 100 and consisted of members of the town council, prominent Fellows of the Royal College of Surgeons of Edinburgh, and all the distinguished guests of the College. The toast of "The Royal College of Surgeons of Edinburgh" was proposed by Sir ROBERT CRANSTON, the Lord Provost, in felicitous terms, and was briefly replied to by the PRESIDENT, Sir PATRICK HERON WATSON.

The great event—the commemoration ceremonial—was held in the afternoon in the McEwan Hall. The area of the hall, the seats in which were all numbered, was reserved to the left of the chair for the Fellows of the College, and to the right of the chair for representatives of other colleges, of various universities, and other learned bodies. Academic costume was worn. The platform and two or three rows of seats in the area were reserved for special persons, including those upon whom the honorary Fellowship was to be conferred and who at the appointed hour entered the hall in procession, the President of the College, with the mace-bearer, leading, followed by the Lord Provost. The raised area and the galleries were occupied largely by ladies. When all had taken their places the aspect of the hall was very striking and effective, the weather favouring the scene and the ladies being in the brightest of summer attire.

The PRESIDENT then rose and delivered a short address of welcome in which he dwelt on the ancient history of the College. The origin of the Royal College of Surgeons of Edinburgh as a corporate body, he said, must be traced back to the reign of James IV. of Scotland. He it was who, on Oct. 13th, 1506, confirmed by Royal Charter the "Seill of Cause" which a year previously, in July, 1505, had been granted to the barber-surgeons resident within the burgh of Edinburgh by the provost, bailies, and council of the burgh. There is, however, reason to believe that even prior to this date an organised body of practitioners had already existed in Edinburgh to whose laudable desire for an accredited position and for authority to practise and to teach the College is indebted for its inception. This body by its energy and indomitable perseverance met and overcame the difficulties which stood in its way; and on recalling to mind the comparatively barbarous condition of the country at that time, and the terrible strife by which it was torn, it is impossible to do otherwise than to regard with admiration and with respect the work which these men were able to accomplish as pioneers of a great cause. At this period Scotland appears to have been placed at a serious disadvantage owing to the early age at which its sovereigns were called upon to ascend the throne. James III. of Scotland, the father of the founder of the College, was but a boy of eight when called upon to occupy this difficult position by the death of his father—James II. The haughty Scottish nobility were incapable of appreciating the King's devotion to intellectual pursuits and great dispeace was thus created which ended in rebellion and, finally, in the death of James at Sauchie in 1488. On the accession of his son, King James IV., the rebellion was subdued and a period of comparative peace was entered upon. King James IV. is described as having been a man of polished and agreeable address, with qualities of mind as outstanding as those of his bearing, while his knowledge of languages appears to have been of a high order, for he spoke, in addition to his own tongue, fluent French, German, Flemish, Italian, and Spanish, and had a good knowledge of the Latin classics. In character he was neither prodigal nor avaricious but liberal when occasion required and he was courageous to the point of rashness. This was the Prince who, by his enlightened qualities of mind, was led to confirm by Royal Charter in 1506 the establishment of the College of Surgeons of Edinburgh. He is said to have made it his special care to provide for the health and the well being of his army by supplying it with surgical aid and it is conceivable that in granting official recognition to the College by the bestowal of a Royal Charter he had before him the possible realisation of this great-minded purpose. The President concluded an eloquent address by first referring all interested in the past of the College to Dr. John Smith's admirable treatise upon its history and then by expressing the deep sense of regret that all Scots must feel at the loss of the late Principal of the University, Sir William Muir.

At the close of the address the secretary, Dr. Francis Cadell, constituted the meeting of the College by reading the following prayer, which is traditionally understood to have been framed by John Knox: "O eternal God, our loving and merciful Father in Christ Jesus—Seeing we are convened to treat of those things which concern our calling, we beseech Thee, O Lord, to be merciful to us and give us grace to proceed therein without malice, grudge, or partiality; so that the things we do may tend to the glory of God, the weal of our vocation, and the comfort of every member of it; through Jesus Christ our only Lord and Saviour. Amen."

The conferring of the honorary Fellowship was then proceeded with. Sir Halliday Croom, Vice-President of the College, acted as promoter, introducing each of the distinguished men upon whom the College had decided to confer this honour and passing on each a short and pithy eulogy. All the names were received with applause, while the whole audience rose to their feet in honour of Lord Lister who was absent. After this most interesting part of the ceremonial some words of thanks and of appreciation were said by the various recipients of the honour who were present. This part of the proceedings had also been well organised, for the words of thanks were as brief and as pointed as were the promoter's. Following are names of those on whom was conferred the honorary Fellowship of the College:—

AUSTRIA.

VON EISELSBERG, ANTON FREIHERR, M.D., Professor of Surgery, University of Vienna.

(*In absentiâ*) FUCHS, ERNST, M.D., Professor of Ophthalmology; Director of the First Division for Eye Diseases in the Allgemeines Krankenhaus, Vienna.

DENMARK.

SAXTORPH, SYLVESTER, M.D., Professor of Clinical Surgery, University of Copenhagen; Surgeon to the Kommune Hospital; Knight of the Order of Danneborg; formerly Surgeon to *His Majesty* the King of Denmark.

FRANCE.

(*In absentiâ*) GUYON, FELIX, M.D., Professor in the Faculty of Medicine, Paris; Surgeon to the Necker Hospital; Member of the Institute; Member of the Academy of Medicine.

[illegible], JUST, M.D., Professor of Surgery in the [illegible]; Member of the Academy of Medicine.

[illegible], M.D., Professor of Surgery in the Faculty of Medicine, Lyons; Corresp[illegible] Member of the Academy of Medicine; formerly Surgeon-in Chie[illegible].

SEGOND, PAUL, M.D., [illegible] in the Faculty of Medicine, Paris; Surgeon [illegible].

(*In absentiâ*) TERRIER, LOUIS FÉLIX, M.D., Professor of Surgery in the Faculty of Medicine, Paris; Surgeon to the Hôpital de la Pitié; Member of the Academy of Medicine.

GERMANY.

[illegible] S. EXC. ERNST, M.D., F.R.C.S. Eng. [illegible] University of Berlin; Royal Prussian [illegible] (*I*[illegible] M[illegible] [illegible]ial Russian Actual Councillor of State; Knight of the Prussian Order of Hohenzollern, the Prussian Kron and Red Eagle Orders; Knight Grand Cross (with Diamonds), Imperial Russian Orders of the Holy Anne, of the Holy Stanislas, and the Holy Vladimir; *General-Arzt of the Prussian Army*, with the rank of Major-General.

BIER, AUGUST, M.D., Professor of Surgery, University of Bonn; formerly Professor of Surgery in Greifswald.

[illegible] VINCENZ, M.D., Professor of Surgery, [illegible]

[illegible]RANZ, M.D., F.R.C.S. Eng. (*Hon.*), Professor [illegible] Clinical Surgery at the Charité Hospital, Berlin; General [illegible] suite of the Army Medical Corps.

(*Sent to relatives*) VON MIKULICZ-RADECKI, JOHANNES, LL.D. Edin., Glasg., and Phila., General Arzt à la suite of the Medical Corps of the Royal Prussian Army; Professor of Surgery and Director of the Surgical Clinic, University of Breslau. *Died June 17th, 1905.*

ITALY.

DURANTE, FRANCESCO, M.D., F.R.C.S. Eng. (*Hon.*), Senator; Professor of Clinical Surgery, Royal University of Rome; Knight of the Most Distinguished Order of the "Merito Civile di Savoia"; Knight Grand Cross of the "Corona d'Italia."

JAPAN.

(*In absentiâ*) SANEYOSHI, BARON YASUZUMI, Director-General of the Medical Department, Imperial Japanese Navy.

RUSSIA.

(*In absentiâ*) SUBBOTIN, MAXIM SEMENOVIC, Chief of the Surgical Clinic, Military Hospital, Imperial Academy of Medicine, St. Petersburg.

SWEDEN.

LENNANDER, KARL GUSTAV, M.D., F.R.C.S. Eng. (*Hon.*), Professor of Surgery and Obstetrics, University of Upsala.

SWITZERLAND.

(*In absentiâ*) KRÖNLEIN, ULRICH, M.D., Professor of Surgery, University of Zürich.

UNITED STATES OF AMERICA.

HALSTED, WILLIAM STEWART, M.D., F.R.C.S. Eng. (*Hon.*), Professor of Surgery, Johns Hopkins University, and Surgeon to the Johns Hopkins Hospital, Baltimore.

KEEN, WILLIAM WILLIAMS, A.M., M.D., LL.D., F.R.C.S. Eng. (*Hon.*), Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College; Surgeon to the Jefferson Medical College Hospital, Philadelphia.

KELLY, HOWARD A., A.B., M.D., Professor of Gynæcology and Obstetrics, Johns Hopkins University; Gynæcologist and Obstetrician, Johns Hopkins Hospital, Baltimore; Corresponding Member of the Société Obstétricale et Gynécologique of Paris and of the Gesellschaft für Geburtshülfe of Leipsic.

(*In absentiâ*) MAYO, WILLIAM J., M.D., Surgeon to St. Mary's Hospital, Rochester, Minnesota.

(*In absentiâ*) WARREN, JOHN COLLINS, M.D., LL.D., F.R.C.S. Eng. (*Hon.*), Professor of Surgery, Harvard University; Surgeon to the Massachusetts General Hospital.

BRITAIN.

(*In absentiâ*) BOMFORD, Lieutenant-Colonel GERALD, M.D., C.I.E., Director-General of the Indian Medical Service.

CAMERON, IRVING HOWARD, M.B., F.R.C.S. Eng. (*Hon.*), Professor of Surgery and Clinical Surgery, University of Toronto; Surgeon to the Toronto General Hospital.

CHANCE, ARTHUR, President of the Royal College of Surgeons in Ireland; Surgeon to the Mater Misericordiæ Hospital and to the Dublin Orthopædic Hospital; Consulting Surgeon to St. Michael's Hospital; President of the Surgical Section of the Royal Academy of Medicine, Ireland.

CLARK, HENRY [illegible] of the Faculty of Physicians and Surge[illegible] of Surgery, St. Mungo's College, Glasgow; [illegible] yal Infirmary; Honorary Associate of the Order of St. John of Jerusalem.

ELLIS, HERBERT MACKAY, Director-General of the Royal Navy Medical Service.

(*In absentiâ*) FITZGERALD, Sir THOMAS NAGHTEN, C.B., M.D., Honorary Surgeon, Melbourne Hospital; Consulting Surgeon, St. Vincent Hospital, Melbourne; Ex-President, Inter Colonial Medical Congress of Australasia; President of the Medical Society of Victoria.

KEOGH, ALFRED HENRY, C.B., M.D., Director-General of the Army Medical Service

(*In absentiâ*) Lord LISTER, P.R.S., D.C.L., LL.D., Serjeant-Surgeon to His Majesty the King.

(*In absentiâ*) MACCORMICK, ALEXANDER, M.D., Lecturer on Surgery in the University of Sydney; Surgeon to the Prince Alfred Hospital, Sydney; Member of the Royal Society of New South Wales.

PLAYFAIR, JOHN, M.D., President of the Royal College of Physicians of Edinburgh; formerly Physician to the Royal Hospital for Sick Children, Edinburgh.

TWEEDY, JOHN, President of the Royal College of Surgeons of England; Emeritus Professor of Ophthalmology, University College; Consulting Ophthalmic Surgeon, University College Hospital; Consulting Surgeon, Royal London Ophthalmic Hospital; President of the Ophthalmological Society, London.

SHEPHERD, FRANK J., M.D., Professor of Anatomy in M'Gill University, Montreal; Lecturer in Operative Surgery.

(*In absentiâ*) M'BURNEY, CHARLES, M.D., Professor of Clinical Surgery, Columbia University; Consulting Surgeon to the New York Hospital.

Thereafter congratulatory addresses were presented by the following bodies :—

The University of St. Andrews.—By the Dean of the Faculty of Medicine (Professor REID) and the Principal of University College, Dundee (Professor YULE MACKAY).

The University of Glasgow.—By the Dean of the Faculty of Medicine (Professor MURDOCH CAMERON).

The University of Aberdeen.—By the Dean of the Faculty of Medicine (Professor R. W. REID).

The University of Edinburgh.—By the Principal (Sir WILLIAM TURNER, K.C.B.).

The Royal College of Surgeons of England.—By the President (Mr. JOHN TWEEDY).

The Royal College of Surgeons in Ireland.—By the President (Mr. ARTHUR CHANCE).

The Royal College of Physicians of Edinburgh.—By the President (Dr. PLAYFAIR) and the Treasurer (Dr. P. A. YOUNG).

The Faculty of Physicians and Surgeons of Glasgow.—By the President (Professor H. E. CLARK).

The Royal Society of Edinburgh.—By the Senior Vice President (Professor GEIKIE).

The Edinburgh Medico-Chirurgical Society.—By the President (Professor CHIENE, C.B.).

The Edinburgh Obstetrical Society.—By the President (Dr. N. T. BREWIS).

The Royal Medical Society.—By the President (Dr. R. J. JOHNSTON).

The Merchant Company of Edinburgh.—By the Master (Mr. JOHN HARRISON).

The Managers of the Royal Infirmary of Edinburgh.—By the Chairman (the LORD PROVOST).

Some of the earlier presented addresses were read but the others were merely handed to the President. This very interesting ceremonial, which passed off without any hitch worthy of remark, was concluded by the singing of the National Anthem accompanied by the organ.

The dinner hours were monopolised by the Fellows of the College in dispensing the most liberal hospitality to friends from the city and the country, as well as to their guests from England, America, and the various countries of Europe. At half-past nine a reception was held by the President and Fellows of the College in the Royal Scottish Museum, at which there were some thousands of guests, the scene being a bright and gay one.

Friday forenoon was free of public function but in the early afternoon the Royal College of Physicians gave a luncheon in the hall of its College in honour of the sister College and of the distinguished guests. The chair was occupied by the President of the College, Dr. John Playfair, and there was a large party of Fellows and guests. The afternoon was devoted to a garden party given by the President and Fellows of the Royal College of Surgeons in the grounds of George Heriot's Hospital. The hospital, which is situated opposite the Royal Infirmary, is one of the finest specimens of Tudor architecture extant and was thrown open to the guests. The grounds are large, the day was bright and warm, and the scene was gay and animated.

In the evening a grand banquet was held in the Music Hall, to which about 350 sat down. The President was supported to right and left by the Lord Provost of Edinburgh, by the French Ambassador, M. Cambon, and other prominent officials and distinguished guests. The hall was beautifully decorated for the occasion and the banquet itself was of a choice description. The loyal and patriotic toasts were proposed in a few words by the PRESIDENT; then the VICE-PRESIDENT proposed "The Lord Provost and Magistrates of the City of Edinburgh," which was responded to by the LORD PROVOST. In both speeches the old relations between the town council and the ancient craft were referred to. "The Honorary Fellows of the College" was then proposed by the PRESIDENT in a few appropriate sentences and was received with much enthusiasm, the company singing "For they are jolly good fellows." Professor Freiherr VON EISELSBERG and Dr. HALSTED replied for the honorary Fellows, the former speaking of Simpson and of Lister, and the latter of the hospitality which had been lavishly bestowed upon them.

The toast of "The Guests" was in the hands of Principal Sir WILLIAM TURNER who in carefully measured terms and eloquent manner spoke of the origin of medical guilds and corporations from the private working of members of the profession and not from the State, for it was found that men could work better in combination than as isolated units. As the outcome of these combinations there emerged a system of medical education, gradually perfecting itself throughout the generations, a method of testing the system of education by examination, and, what he thought was of more importance within the profession even than these matters, a sentiment of professional honour—a code of conduct which should regulate the action of medical men towards each other and towards the great public with which they were so intimately associated. Many of the guests recognised the value of that corporate combination. Their guests from the continent, however, had come there because they remembered that they were all members of a common profession whose function it was to probe into the causes of disease, to do what seemed to them to be the best to get rid of the causes of disease, and to put the practice of medicine on a wide and proper footing. It was not one country that did that, it was by a combination of all the countries where medical science was practised, and he illustrated this by reference to Pasteur, Lister, and Koch. He ventured to think that there was a wider significance in their meeting that evening. It was more than a mere professional gathering for they were honoured with the presence of the Ambassador for the great Republic of France. Sir William Turner referred in glowing terms to the old connexion of Scotland with France, the greatness of France and of the French people, and hoped that brotherly love between the two peoples might ever prevail. That this admirable speech, every syllable of which was heard in every part of the hall, had expressed the sentiments of the whole company was shown by the shouts of applause with which it was received. When M. CAMBON rose to reply the whole company rose and gave him an ovation which could not be surpassed in its evident spontaneity and the warmth of its expression. M. Cambon must have felt that the *entente cordiale* had a deeper foundation than mere statecraft or diplomatic understanding.

The last toast on the list was in the name of Sir JOHN URE PRIMROSE, the Lord Provost of Glasgow, and "The Royal College of Surgeons of Edinburgh" could not have been in more capable hands. After referring to the 400 years during which the College had existed as full of momentous issues for Scotland, for Britain, and for the world, he proceeded to pass a high eulogy upon the profession of medicine and surgery. He said that, as one who had participated in civic administration and had felt that underlying it was the doctrine of making this world brighter, happier, wholesome, and a more desirable dwelling place for the human unit, and as one who had loyally held to that doctrine, what a debt of gratitude they owed to the medical profession in all its branches. He expressed, also, great faith in the future of medicine, for he believed that the most eminent men in that assembly would confess that as yet they stood on the threshold of the investigation of causation and cure, and the mind that assumed that attitude, with lowliness and meekness, but with sincerity, was the truest and most possible force in future achievements. He believed that for years to come from the ranks of a college such as this, and inspired by the traditions of a college such as this, many men would rise to confer benefits on their fellows that would justly entitle their fellows to call them blessed. This toast was briefly responded to by the PRESIDENT who acknowledged the high conception formed by the proposer of the toast of the duties of the medical man. Thereafter the company joined in singing the National Anthem, followed by "Auld Lang Syne."

This brought to a close the official programme of the College and it only remains to compliment those concerned upon the administrative faculty shown by the celebration secretary, Mr. John W. Dowden, F.R.C.S. Edin., and the group of younger surgeons upon whom much of the labour of the arrangements necessarily fell, and to congratulate the President and the Fellows of the College on the manner in which all the proceedings were carried through and upon the public interest shown in the College.

On Saturday the University of Edinburgh held a special graduation ceremonial with the object of conferring the honorary degree of Doctor of Laws upon the foreign, American, and colonial guests of the Royal College of Surgeons. The following were thus honoured:—The French Ambassador, His Excellency M. Paul Cambon; Professor Irving Howard Cameron, Dr. Just Lucas-Championnière, Professor Francesco Durante, Professor Anton Freiherr von Eiselsberg, Professor William Stewart Halsted, Professor William Williams Keen, Professor Karl Gustav Lennander, Professor Saxtorph, and Professor F. J. Shepherd.

Principal Sir WILLIAM TURNER, at the close of the capping ceremonial, said it was not customary to have replies from the recipients of the honour but as this was a special occasion he thought it would be gratifying to the Senatus and to many of the friends assembled if he requested the French Ambassador to speak a few words on behalf of the European honorary graduates and Dr. Keen on behalf of those who came from the other side of the Atlantic.

M. CAMBON, speaking in French, made complimentary reference to the honour which the University had conferred upon him and proceeded to speak of the illustrious position of the University of Edinburgh and of the traditional friendship between France and Scotland and of the pleasure that it had given him to visit Edinburgh.

Dr. KEEN said that he and his transatlantic brethren came to Edinburgh as their academic Jerusalem—beautiful for situation, the pride of the whole earth. They were not strangers. They had been encompassed with kindness and they had not only been "capped" but "captured."

The proceedings concluded with the benediction.

THE PROPOSED AMALGAMATION OF THE LONDON MEDICAL SOCIETIES.

THE following is the report of the executive committee to the committee composed of representatives of the societies, which was accepted by the committee on Wednesday, July 19th. We deal with it in a leading article this week:—

Your committee beg to report that in accordance with their powers they coöpted Mr. Makins and appointed Dr. Arthur Latham and Mr. Herbert S. Pendlebury to act as honorary secretaries.

We instructed Messrs. Newson-Smith, Lord, and Mundy, chartered accountants, to investigate the rolls of membership and the accounts of the following societies:—Medical; Royal Medical and Chirurgical, Pathological; Clinical; Obstetrical; Gynæcological; Neurological; Epidemiological; Medico-Psychological; Ophthalmological; Laryngological; Laryngological Otological-Rhinological Association; Otological; Dermatological of London; Dermatological of Great Britain and Ireland; Society for the Study of Diseases of Children; Odontological; Association of Medical Officers of Insurance Companies; Balneological; Society of Anæsthetists; Electro-Therapeutic; Therapeutic.

The accountants inform us that the 22 societies whose membership lists were collated have a total membership of 7229, constituted by 4997 persons. Of these 3725 are members of one society only, and the balance, 1272, are members of [illegible]

The accountants, upon th[illegible] e societies, further inform us th[illegible] bequests and trust funds) over liabilities of these societies is more than £40,000. If 3800 members of societies other than the Royal Medical and Chirurgical Society become members at a subscription of £1 1s. per annum the new society will have a small balance of income over expenditure. If any members of these societies become Fellows at a subscription of £3 3s. per annum the balance will be proportionately increased. This estimate is based on the present income and expenditure of the Royal Medical and Chirurgical Society, together with the present income and expenditure of 17 other societies, as given in subjoined table, and makes no allowance for any economies which may be effected by the union.

Estimate of Income and Expenditure of the proposed Royal Society of [illegible] housed at 20, Hanover square, on Basis of Income and Expenditure of existing 18 Societies for the Year ending Dec. 31st, 190[illegible].

EXPENDITURE.		INCOME.	
Royal Medical and Chirurgical Society	£4,307	Royal Medical and Chirurgical Society	£4,911
Loss of rent by union	770		
Of other 17 Societies.		*Of other 17 Societies.*	
"Transactions," less sales but without allowance for income by advertisements ...	2,545	Rent of Medical Society	940
Staff	650	Investments	350
[illegible]	166	Interest from investment of present cash balance	50
[illegible]	121	Entrance fees	166
[illegible]ture	1,670	3800 subscriptions at £1 1s	3,990*
Balance	198		
	£10,427		£10,427

* The actual amount received last year from subscriptions by these 17 societies was £5033.

In view of the facts that 3525 persons already subscribe £1 1s. to these 18 societies per annum, that 1272 pay from £2 2s. upwards, and that under the proposed scheme many individuals who are not Fellows of the Royal Medical and Chirurgical Society would become Fellows of the Royal Society of Medicine at an annual subscription of £3 3s., your committee consider that the new society would have a sufficient balance of income over expenditure to provide for improvements and for any sinking fund rendered necessary by extensions to 20, Hanover square, supposing that all the scheduled societies joined.

This is shown more clearly from the following estimate of subscriptions which may be received from members of the various societies who are not Fellows of the Royal Medical and Chirurgical Society:—

	£
600 members of societies as Fellows at £3 3s. ...	1890[1]
3200 members at £1 1s	3360
Library subscriptions at £1 1s., say	525
	£5775

If this £5775 replaces the conservative estimate of £3990 from subscriptions in the foregoing estimat[illegible] the [illegible] estimated annual balance of £198 [illegible] further information as to the fina[illegible] until we know exactly which societies have definitely decided to join the proposed Royal Society.

Your committee suggest that every member of the societies which shall amalgamate shall have the option of joining the new society without entrance fee and that as far as possible the members of these societies shall retain their present privileges in the new society. For example, any Fellow of the Royal Medical and Chirurgical Society who has compounded for his subscription will be entitled to join the Royal Society of Medicine as a Fellow without further payment of any kind and a member of any society who has compounded for his subscription [illegible] section of the Royal Society of [illegible]

Your c[illegible] suggestions might be embodied [illegible] new society, namely, that—

1. The new society shall be called the Royal Society of Medicine, or the Royal Academy of Medicine, according to the vote of the societies concerned.

2. All moneys, books, premises, and other properties belonging to any of the societies which join the proposed union shall become the property of the new society.

---

[1] This figure 600 is arrived at as follows: 1272 members belong to two or more societies, the figures, taking 1300 instead of 1272, show that—

751 members belong to two societies
300 " " three "
134 " " five "
72 " " six "
31 " " seven "
5 " " eight "
6 " " nine "
1 " "

The number of Fellows of the Royal Medical and Chirurgical Society paying an annual subscription of £3 3s. is 420 (many of these probably belong to no other societ[illegible] but if we deduct their entire number from [illegible] 1272 there are at [illegible] societies. The co[illegible] become Fellows of [illegible]

3. The society shall be housed at 20, Hanover-square. Increased accommodation, if required, can be obtained by extending the premises and by the absorption of certain rooms now occupied by tenants of the Royal Medical and Chirurgical Society.

4. The society shall meet four or more times a year to discuss subjects of medical and scientific interest.

5. The society shall consist of the following sections, with power to add new sections or to modify existing ones with the consent of the members (1) Anæsthetic; (2) Clinical; (3) Dermatological; (4) Diseases of Children; (5) Epidemiological; (6) Laryngological, Otological, and Rhinological; (7) Medical; (8) Mental Medicine (Psychiatry); (9) Neurological; (10) Obstetrical and Gynæcological; (11) Odontological; (12) Ophthalmological; (13) Pathological; (14) State Medicine; (15) Surgical; (16) Therapeutical, including General Therapeutics, Pharmacology, Electro-therapeutics, Balneology, and Climatology. It is hoped that in the early future an anatomical and physiological section may be formed.

6. The society shall consist of Fellows, Members, Honorary Fellows, and Honorary Members.

7. The Fellowship of the society shall be restricted to those who are registered medical practitioners of the British Empire and to men whose scientific attainments are satisfactory to the general council.

8. A Fellow shall pay, subject to any future by-law, an annual subscription of £3 3s., and shall have the right to attend all meetings of the society or of any of its sections, and shall have full use of the library. After the society is constituted (i.e., after a date to be subsequently determined) a new Fellow shall pay an entrance fee of £2 2s.

9. Each section shall have the power to elect as members of the society such persons as the council of the section may think fit, provided that the names of the candidates proposed for election be previously submitted by the sectional council to the council of the society for their approval.

10. A member of any particular section shall pay, subject to any future by-law, £1 1s. per annum, and shall have the right to attend all the meetings of his section, but must pay an additional £1 1s. per annum if he wishes to have the use of the library, and a further subscription of 10s. 6d. per annum for each additional section.

11. The general management of the society shall be under the control of a general council, consisting of the president, the presidents of the various sections, two treasurers, two librarians, two secretaries, and eight other Fellows.

12. The entire management of the funds of the society shall be in the hands of a finance committee, subject to and acting as a sub-committee of the general council.

13. In order to enable existing societies to retain their individuality as far as possible each section shall have power to make the necessary laws and regulations for the conduct of its business.

14. The presidents of sections shall be *ex officio* vice-presidents of the society, and shall serve on the general council of the society.

15. In the estimate provision has been made for a monthly publication (July, August, and September excepted), to be called "The Proceedings of the Royal Society of Medicine." This publication will be under the control of an editorial committee, and will contain a record of the work of each section during the previous month. By such prompt publication the value of the records will be greatly increased. In addition, the committee will select, subject to the approval of the general council, such papers as they may consider worthy of publication in the "Transactions" of the society.

The committee further suggest that it would be to the advantage of the Royal Society if a committee were formed of representatives of the various sections, charged with the duty of receiving all papers to be read before the society or its sections. This committee should have power to decide before which section any given paper should be read, and to decide whether other sections or the whole society should be asked to join in the discussion. Authors of papers should have the privilege of suggesting the section or sections before which they wished to read their papers.

It is hoped greatly to increase the value of the present library at 20, Hanover-square, and to provide an additional reading room for the use of Fellows and members.

Your committee ask the various societies concerned to consider the scheme submitted at an early date and to inform the honorary secretaries of their views. As soon as the committee is in possession of these views further steps can be taken.

In conclusion, your committee beg to express the unanimous opinion that the union of medical societies will do much to enhance the prestige of British medicine, that it will increase the value of the work at present carried out by existing societies, and that it will be to the great convenience of the medical profession.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE annual meeting of this association was held at the Medical Society's rooms, Chandos-street, London, W., on July 20th and 21st.

On the opening day the chair was occupied during the earlier portion of the meeting by the President, Dr. R. Percy Smith, and after the purely business portion had been transacted by the new President, Dr. T. Outterson Wood. There was a very large attendance of members from all parts of the kingdom. Dr. Percy Smith was heartily thanked for his services as president during the year. Dr. Wood, on taking the chair, was cordially received.

In his Presidential Address Dr. Wood sympathetically referred to the death of the late Sir John Sibbald and proceeded to compare the position of the association with that of 25 years ago. In 1880 there were 394 members and to-day there were 680. The success of the association had been much helped by the formation of subdivisions. He proceeded to call attention to the responsibility resting upon medical men in prescribing powerful drugs and the ease with which patients could obtain them in unlimited quantity by taking the prescription from one druggist to another. Such poisons had been used for committing suicide. On the question of incipient insanity he referred to the action of the association in recommending that a patient whose insanity was doubtful should be placed under care and treatment away from home on the application of a relative to a magistrate, which action was supported by the British Medical Association. He then alluded to the abuse of the practice of "single care" by advertisers who had no knowledge of the treatment of the insane. He advocated as a remedy the registration of places and persons taking mental cases, especially including the so-called "nursing homes." The President also touched upon the question of voluntary boarders in public asylums and said that there was a field for extension in the direction of encouraging the early treatment of incipient insanity. The address dealt very fully with the question of nursing the mentally afflicted. There were now 6900 nurses, male and female, holding the association's certificate for proficiency, probably the largest number of any organisation in the nursing world holding certificates of uniform value from one constituted authority. Last year the period of training was definitely fixed at three years, which would give the association's nurses a status that they had never before enjoyed. He objected to referring to male nurses in asylums as "attendants," and much preferred the term "nurse" for both sexes. Some members had advocated the principle of substituting female nurses for male to look after male patients, but he thought the proportion of suitable cases for that could not be large. A temperate letter appeared in the *Asylum News* from a matron, stating that a kind heart, common sense, devotion to duty, and loyalty to proper authorities were not the sole prerogatives of women and that a man with those qualities could nurse insane men as well as, and with greater propriety than, any woman. The President called special attention to the importance, in the case of a nurse, of a good personal character and individual fitness for the work, and if the association would be prepared to take one more step towards bringing its nurses into line with the members of the Royal British Nurses' Association and the Midwives Board a registration board might be established which could make it compulsory for each nurse to qualify for the certificate. He was not sure that all the stir now being made about State registration would be of much material benefit to the nurses themselves, nor that the perking them up with a glistering pride might not end in their wearing a crown of sorrow. Whatever might be the outcome of the movement in regard to the State registration of nurses, he doubted if any scheme could improve upon the excellent system of the Royal British Nurses' Association under the presidency of Her Royal Highness the Princess Christian, to whom the association was largely indebted for the interest which she took in the status of asylum-trained nurses. In conclusion, the President declared that psychological medicine was now more intimately associated with general medicine than formerly, and he trusted that it would continue to be the object of the association to strengthen the bonds which united them and which he believed would ere long bring them into one harmonious whole.

Dr. George M. Robertson, medical superintendent of the Stirling District Asylum at Larbert, Stirlingshire, introduced for discussion the question of the Employment of Female Nurses for the Care of Insane Men. He argued that nursing was better done by women and that they were more tidy, bright, genial to patients, and looked better after the cleanliness of bedding and linen than did male nurses. Patients also were more amenable to tactful management by them, but he thought that cases of delirium tremens, acute mania, and dangerous suicidal tendency were best placed in the care of male nurses. As a system the female nursing of male patients, he argued, was to be encouraged. In Scotland it was tried and found to be successful and the Scottish

Commissioners in Lunacy spoke of it in high terms.—In the discussion which followed Dr. ROBERT JONES, medical superintendent of Claybury Asylum, referred to the economic aspect of the question. He thought that the matron should not be loaded with the responsibility of having the charge of male patients.—Mr. JOHN F. BRISCOE criticised Dr. Robertson's statements and conclusions as somewhat one-sided. Those types of insanity, he argued, which tended nowadays to be of the quiet type (demented or depressive), and easy to manage, might be nursed by women but the majority of men required male nursing.—Another speaker said that they could do with female nurses in easy cases but in certain specially difficult male cases (epileptics, maniacs) they could not do without male nurses.—Dr. DAVID THOMPSON, medical superintendent of the Norfolk County Asylum, preferred the male nursing of patients. He found male nurses quite as good as, and even better than, female nurses both in his own asylum and at asylums at the Hague and elsewhere on the continent. Nursing, like cooking and dressmaking, was not the exclusive province of the female sex, and when good male nurses were met with they surpassed the women as men also did in cooking and dressmaking. In cases of delirium tremens male nurses were a *sine quâ non.*—Dr. C. HUBERT BOND of the Ewell Colony for Epileptics found female nursing suitable in the case of his patients, whether male or female.—Dr. BEDFORD PIERCE said that they should not ignore the fatherly instinct of man which made him as good and tender a nurse as the motherly instinct of woman constituted her a nurse. He thought that Dr. Robertson's observations were fallacious and did injustice to the class of male nurses.—Dr. G. E. SHUTTLEWORTH said that if the plan of female nursing as advocated by Dr. Robertson were carried out to its logical limit it would produce a mere "bread-and-cheese class of nurses."—The PRESIDENT, in summing up the discussion, said that male nurses were in certain circumstances more proper than females in the nursing of male cases; female nursing had also its acknowledged merits, but if it was pushed too far it would diminish the goodness of a good work.

On July 21st, in view of the introduction of two Lunacy Bills before Parliament (now withdrawn) the treatment of insanity and the proper accommodation to be provided, especially for early mental disorders, was the first subject of discussion of the day. In introducing the subject the PRESIDENT referred to the two Bills in question—namely, (1) a Bill to Amend the Lunacy Acts, printed on April 17th, 1905, presented to the House of Commons by the Attorney-General and supported by the Solicitor-General; and (2) a Lunacy Acts Amendment Bill to authorise the London County Council to provide receiving houses for the reception of persons mentally afflicted or alleged to be of unsound mind and to authorise the detention of such persons in such houses and for other purposes connected therewith. This Bill was presented to the House by Sir John Batty Tuke, and supported by Mr. John Burns, Mr. Williams Benn, Mr Claude Hay, and others. The technical provisions of the Bills and the bearings thereof on lunacy practice were discussed by several members present.

As germane to this discussion Dr. HELEN BOYLE, late assistant medical officer at Claybury Asylum, read a paper upon Some Points in the Early Treatment of Mental and Nervous Cases, with special reference to the Poor.

Dr. J. MILSON RHODES (a member of the committee which reported recently upon asylums in the United States) read a paper upon the Provision of Suitable Accommodation for the Various Forms of Insanity. He said that he did not believe that insanity was increasing faster than the population. He thought that British asylums were very good as regards accommodation for patients and administration and that they were admirably staffed in comparison with asylums abroad. The French, he said, praised the British asylum system, the medical officers, the attendants, and the lunacy laws. The number of the Commissioners in Lunacy wanted increasing; the public asylums were as good as any in the world, but the parochial spirit should give way to broader views as regards the erection of new asylums. Custodial institutions for chronic cases of lunacy were bad in theory and in practice. Economy was given as the reason for their continuance but that was the only redeeming feat[illegible] and garden[illegible]ng patients" [illegible]ing [illegible] stimulated to work.

Dr. ALAN MCDOUGALL contributed a paper on the David Lewis Manchester Epileptic Colony which was opened in September, 1904, for the treatment of sane epileptics at Alderly Edge, Cheshire. The colonists were provided with industrial occupation and recreation while the mode of life and the diet adopted were those best adapted to ameliorate or to cure their malady. Interesting details were given of the system of buildings, the dormitories, and the workshops. A uniform charge of 14*s.* a week was made to adult colonists. Males and females were received. Special arrangements were made for the training and treatment of epileptic children.

The question of pulmonary tuberculosis in asylums was brought up for discussion in a paper by Dr. GEORGE W. GREENE, assistant medical officer of Claybury Asylum, read by Dr. ROBERT JONES in the absence of the author.—In the discussion following the paper several speakers took part.—Dr. ROBERT JONES gave an interesting account of the mortality from pulmonary tuberculosis as based upon the returns of deaths and post-mortem examinations at the various London county asylums.—Dr. F. G. CROOKSHANK said that the conclusion which he had published seven years ago, to the effect that the death-rate from pulmonary tuberculosis in the asylum population was ten times that from the same disease in the general population, was in no way discredited by Dr. Greene's arguments. He thought that Dr. Greene had confused the death-rate from pulmonary tuberculosis in the insane with the proportion of deaths due to that disease generally.—Further remarks were made by Dr. LIONEL A. WEATHERLY on the System of Warming and Ventilation in Sanatoriums; by Dr. W. LLOYD ANDRIEZEN on Segregation, Diagnosis of Incipient Phthisis, and "Tent Life" for the Tuberculous Insane (of which a graphic account was cited as practised in the United States by Dr. MacDonald of Manhattan Asylum); by Dr. T. DRAPES of Ireland, who condemned steam heating; by Dr. ROBERTSON, Dr. A. R. URQUHART of Perth (who gave credit to Dr. Toulouse of the Villejuif Asylum, France, for the open-air system of treatment which he had adopted as long as 12 years ago), by Mr. H. F. HAYES NEWINGTON, and by the PRESIDENT, after which Dr. JONES replied.—The proceedings then terminated.

THE CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

THE annual meeting of the Royal Institute of Public Health was held in London from July 19th to 25th at the Polytechnic, Regent-street, and at King's College, Strand, under the Presidency of the MARQUIS of LONDONDERRY.

SECTION OF PREVENTIVE MEDICINE.

Sir JAMES CRICHTON-BROWNE, the Lord Chancellor's Visitor in Lunacy, presided over this section which was held in the Polytechnic, Regent-street. Sir James Crichton-Browne took for the subject of his address

The Prevention of Senility.

The value of preventive medicine, he pointed out, was shown by the diminution of the death-rate as a whole. There were three great epochs of life—namely, growth, equilibrium, and decline—but that division was by no means precise, for the boundaries of the epochs were ill-defined. It was literally true that "we die daily and are daily born again." The processes of decay followed on the beginnings of growth and formative energies were still at work when only decay seemed to be in possession. It was a good working hypothesis to say that the natural life of man was 100 years. Every man was entitled to his century and every woman to a century and a little more. Children should be brought up impressed with the obligation of living to 100 and they should be taught how to avoid the irregularities that tended to frustrate that laudable ambition. To lengthen as well as to strengthen the lives of the people was the object of preventive medicine. Regular employment must be secured and poverty diminished, so that they might no longer have amongst them 13 millions on the verge of hunger and dying in multitudes before their time. These things were beyond the scope of preventive medicine but within its sphere; although much had been done much remained to be done. If old age were to be attained a good start in life must be given, hence the importance of questions such as infant feeding and milk-supply; the degeneration of the people must be arrested by giving them decent houses and promoting their physical development by affording them facilities for exercise.

Diet and Disease.

Dr. J. HADDON read a paper on this subject, remarking that he lived on one meal a day and ate no animal product except butter.

The PRESIDENT of the section said the reader of the paper was enthusiastic but pointed out that enthusiasm often degenerated into faddism. It ought to be remembered that concurrently with the decrease in the death-rate there had been an increase in the consumption of meat. Nature was against one meal per day.

Dr. S. G. MOORE (Huddersfield) read a paper on

Infantile Mortality.

He said that in the worst parts of some of the great cities only three out of four children born lived for 12 months. With regard to supplying milk for infants he advocated the formation of children's dispensaries, such as existed in France. Misleading statements relating to food should be stopped. Some of the foods advertised for infants caused many deaths. He knew of one article freely advertised as a special food for infants which upon analysis proved to be nothing but baked flour, not only insufficiently nutritive but even injurious to children.

Dr. T. N. KELYNACK opened a discussion on

Sanatoriums for Consumptives.

He said that one-third of all the deaths from consumption in London took place in Poor-law institutions. There were now some 70 sanatoriums in the United Kingdom, with accommodation for about 2760 patients, but the beds available for the working classes and destitute were very few, and even in the best of our paying institutions for the poor beds had to be kept vacant owing to lack of funds. In regard to the poor public effort was merely touching the fringe of the difficulty. It was well to remember that we were still in the experimental stage of our research. He advocated a direct controlling body which could deal with all cases of pulmonary tuberculosis throughout the country. The time was ripe for a Government inquiry into the methods of treatment of the consumptive poor.

SECTION OF MUNICIPAL ADMINISTRATION OF THE EDUCATION ACTS.

This section also met at the Polytechnic, where the President, Mr. J. H. YOXALL, M.P., gave an address on

Secondary Education.

What was wanted, he said, for the bulk of children who were transferred from elementary schools to places of secondary education was a continuative education which would fit them for the higher posts of service in the world of industry and commerce and not the kind of education which would lead up to the learned professions.

Ventilation of Public Buildings.

Mr. J. H. BLIZZARD, after remarking that properly ventilated and sanitary school buildings were the foundation upon which the medical profession should start to prevent the spread of infectious disease, referred to churches which he said were the best places for the spread of pulmonary tuberculosis and the dissemination of the germs of infectious diseases.

Medical Inspection of Schools.

Sir GEORGE KEKEWICH advocated the appointment by the Board of Education of a medical officer whose duty should be to see that local authorities appointed a medical officer to inspect every school in the country and to report on its sanitary condition and the health of the children. He was also of opinion that there should be a thorough inquiry into the sanitary condition of all schools and that those found to be seriously defective should be eliminated.

SECTION OF CHILD STUDY AND SCHOOL HYGIENE.

Training of Teachers.

Lord STANLEY of ALDERLEY presided over this section which was held at the Polytechnic and in his address dwelt upon the necessity of teachers possessing some preliminary training in biology and physiology.

ENGINEERING AND BUILDING CONSTRUCTION.

Sir ALEXANDER BINNIE presided over this section which was opened in the Polytechnic and delivered a most interesting address on

The Drainage of London

which was both historical and practical as regards modern conditions.

A paper was read on the Destruction of Town Refuse by Councillor ATKINSON (Hull), and at King's College, Strand, Mr. C. G. MOORE discussed

Problems in Practical Disinfection.

He dwelt on the ineffective character of many of the routine methods of disinfection and called attention to the variable and often valueless character of the so-called disinfectant fluids of commerce. Although the disinfection of clothes and other fabrics was practised by some sanitary authorities it was neglected very largely in districts which had failed to understand the importance of providing that means against the spread of infection.

Dr. DAVID WALSH read a paper on

How to Sterilise London Drinking Water.

Referring to the contamination of the Thames by sewage, he said that hitherto it had not been possible to sterilise sewage on a very large scale but now it could be done by the Salvator apparatus which had been tested and found to render water absolutely sterile. By its aid water could be rapidly sterilised and delivered cool, sparkling, and palatable. The same machine could be used to sterilise all sewage effluents discharged into the upper Thames.

Smoke Abatement.

A paper on this subject was read by the Hon. ROLLO RUSSELL. He expressed the opinion that kitchen and ordinary domestic fires were the main cause of London fogs. The remedies he suggested were improved methods of heating but the best of all remedies, he said, would be the removal of the people of London to the country.

The Air Supply of London.

Dr. T. GLOVER LYON read a paper dealing with the question of supplying fresh air to London and said that "tube" railways could be arranged to supply pure air to the central part of the city and to remove vitiated air from it. There ought to be a department of public Health presided over by a Minister sitting in the Cabinet.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 28, 1827.

ASSISTANT SURGEONS IN THE NAVY.[1]

To the Editor of THE LANCET.

SIR,—I am surprised that you should have inserted in a former number of THE LANCET, the fastidious and unfounded complaints of "An Assistant Surgeon in the Navy." He talks about being degraded to mess in the midshipman's berth, "with unruly boys." What! is it a degradation for a medical school-boy (for such, in point of practical experience is a young assistant surgeon,) is it a degradation, I ask, to mess with a young Rodney, a Howe, a Duncan, a Nelson! Doubtless, if this assistant had been *so* degraded, he would have gloried in his shame, and stood "a tip toe" when their names were mentioned. "Surely," says this Assistant Surgeon, "his education, and respectability as a medical man, entitle him to rank with any lieutenant, master, purser, or marine officer in the Navy." Now, Sir, neither respectability nor education entitle any officer to rank; and no such degree of them, as thirteen years' experience have enabled me to observe in assistant-surgeons in the navy, will render them superior in general information to the junior officers, whose society this gentleman deems so unruly. I do not hesitate to say, that in any midshipman's berth he ever entered, there was as much respectability, and as much education, before his entrance as after it. Non omnia possumus omnes; even the medical gentleman himself is not *ground* in all knowledge. Is there no education but what is anatomical? Is there no respectability but what is medicinal? Are the sciences exclusively medical? Is plane trigonometry concentrated in the carving of lozenges, or spherical in the rolling of pills? Surely, Sir, there is no less absurdity in comparing the "airy apartments of a house on shore, to the necessary confinement of a ship; and in complaining of his want of accommodation, there is no less injustice in the statement of the Assistant Surgeon. When the junior officer—the unruly boy—the offensive messmate of this respectable and educated assistant, is "biding the pelting of the pitiless storm," he, "good easy man," is snugly housed between decks, reading books, learning, or most probably picking bones. When the "degraded" midshipman is on the high and giddy mast, watching the out-hauling of a weather earing, the scientific "idler," as he is not inaptly called at sea, is either elaborating an extract, or rotating a pill; and instead of being recommended by the wet or cold, his manipulations are aided *laterally* by the rolling of the ship, and *anteriorly* by her pitching; in short, Sir, he is at perfect liberty to take every advantage of the wind and weather.

---

[1] See letter from "An Assistant Surgeon in the Navy" reproduced under the heading of "Looking Back" in THE LANCET of June 24th, 1905, p. 1750.

In battle too, when the "unruly boys" are lifting their voices amidst the roar of cannon, and surrounded by "the pride, pomp, and circumstance of glorious war," the respectable medical assistant is doing his duty, deeply sunk in a bomb proof element.

The education of this respectable assistant has taught him, it seems, that it is very warm in hot climates, so much so, indeed, as to render it agreeable to dine with the coat off. Forsooth this hot weather and close apartments, are insufferable to our gallant assistant; it is by no means salubrious "Look," says he, "at the army medical man dining in a comfortable airy apartment, and enjoying all the luxuries of the *shore*." It is certainly natural for the human members to take care of the human belly, and especially for medical members to consider a medical belly; but there is somewhat too much of this, even in a respectable assistant surgeon, who has been so many years in the naval service. He appears to me, what his messmates, the unruly boys, would certainly call him, a shore-going doctor. "Look again," says he, "at the army medical man, who has his quarters allotted to him with every convenience that can be procured on *shore*." I suppose such an assistant would have the ship herself on *shore*.

The Assistant Surgeon invidiously notices, "That the gunner, boatswain, and carpenter, are each entitled to a cabin." Now, Sir, had his superior education only lifted his mind from the mortar, to contemplate the reason of the circumstances which stood around him, and had his respectability permitted him, he might have perceived that these warrant officers are each of them at the *head* of their respective professions, and can attain no higher station, and should therefore justly be allowed as many privileges as may render their situation a desirable one, to excite the emulation of such as may seek it. He would not thus have complained, that such privileges were withheld from an assistant surgeon, to whom are open the superior ranks of surgeon and physician, with their respective profits and accommodations. The Assistant Surgeon complains that he is obliged to sleep in a hammock "like one of the lowest rank;" why, Sir, all his messmates sleep in hammocks, the lieutenants, the captain, and even the admiral himself sleep in "cots," a species of hammock, and sometimes prefer the hammock itself! What, in the name of Æsculapius, would the assistant sleep in? "Airy apartments, quarters allotted to him, dressing tables, &c." Why, Sir, even the Lord High Admiral himself dispenses with these things. With respect to his comparison between the pay of the medical men in the army and navy, it least of all becomes one of his class to make the complaint. It is true that the navy generally is paid far inferior to the army. But both in pay and convenience the naval assistant surgeon is better accommodated than any of his rate on board, and the full surgeon than his rate; the assistant surgeon's pay is far greater than a midshipman's who has served ten or twelve years; he has no watch to keep, and is never exposed to the inclemency of the weather. By inserting this letter, you will do but justice to the government of the navy, as it respects assistant surgeons.

I am, Sir,
Your obedient humble servant,
G. H. H.

Dublin, June 29, 1827.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8900 births and 4002 deaths were registered during the week ending July 22nd. The annual rate of mortality in these towns, which had been 12·7, 11·6, and 12·9 per 1000 in the three preceding weeks, further rose to 13·4 per 1000 last week. In London the death-rate was 12·7 per 1000, while it averaged 13·7 in the 75 other large towns. The lowest death-rates in these towns were 3·1 in Hornsey, 5·5 in Bournemouth, 5·8 in Smethwick, 6·0 in Burton-on-Trent, 6·2 in Hastings, 7·6 in Handsworth (Staffs.), 7·7 in Derby, and 7·8 in Gateshead; while the highest rates were 18·4 in Sunderland and in Merthyr Tydfil, 18·9 in Great Yarmouth, 19·1 in Stockport, 19·9 in Barrow-in-Furness, 20·5 in Oldham, 22·1 in Liverpool, and 24·1 in Bootle. The 4002 deaths in these towns last week included 612 which were referred to the principal infectious diseases, against 371, 388, and 486 in the three preceding weeks; of these 612 deaths 431 resulted from diarrhœa, 64 from measles, 45 from whooping-cough, 32 from diphtheria, 24 from scarlet fever, and 16 from "fever" (principally enteric), but not any from small-pox. No death from any of these diseases was registered last week in Hornsey, Bournemouth, Great Yarmouth, Burton-on-Trent, King's Norton, Derby, Tynemouth, and Newport (Mon.), while they caused the highest death-rates in Aston Manor, Stockport, Birkenhead, Liverpool, Bootle, Leeds, Sheffield, and Sunderland. The greatest proportional mortality from measles occurred in Birkenhead, Barrow-in-Furness, and Sunderland; from whooping-cough in Aston Manor; and from diarrhœa in Hanley, Aston Manor, Stockport, Birkenhead, Liverpool, Bootle, Wigan, Leeds, Sheffield, and Merthyr Tydfil. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns, and no death from small-pox was registered during the week. The Metropolitan Asylums Hospitals contained three small-pox cases at the end of last week, against four, five, and four at the end of the three preceding weeks; no new cases were admitted during the week, against one, two, and two in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2473, 2499, and 2520 on the three preceding Saturdays, had declined again to 2485 on Saturday last, July 22nd; 304 new cases were admitted during the week, against 334, 354, and 356 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 140, 90, and 104 in the three preceding weeks, further rose to 117 last week, but were three below the number in the corresponding period of last year. The causes of 47, or 1·2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Salford, Leeds, and in 46 other smaller towns; the highest proportions of uncertified deaths were registered in Liverpool, Warrington, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·5, 14·7, and 14·3 per 1000 in the three preceding weeks, further rose to 15·2 per 1000 during the week ending July 22nd, but was 1·8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·0 in Leith and 13·0 in Dundee, to 16 5 in Paisley and 19·8 in Perth. The 510 deaths in these towns included 22 which were referred to diarrhœa, 21 to measles, 12 to whooping-cough, three to diphtheria, two to "fever," and one to scarlet fever. In all 61 deaths resulted from these principal infectious diseases last week, against 65, 57, and 55 in the three preceding weeks. These 61 deaths were equal to an annual rate of 1·8 per 1000, which was 0·2 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 14, 13, and seven in the three preceding weeks, rose again last week to 22, of which 16 occurred in Glasgow, two in Edinburgh, and two in Dundee. The deaths from measles, which had been 17, 14, and 19 in the three preceding weeks, further rose to 21 last week, and included 14 in Glasgow, four in Edinburgh, and two in Perth. The fatal cases of whooping-cough, which had been 31, 26, and 25 in the three preceding weeks, further declined last week to 12, of which seven were registered in Glasgow and two in Paisley. The deaths from diphtheria, which had been one, three, and one in the three preceding weeks, rose again to three last week and included two in Edinburgh. Of the two deaths from "fever," one from typhus occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 68, 65, and 65 in the three preceding weeks, further declined last week to 62, and were 13 below the number in the corresponding period of last year. The causes of 13, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 14·9, 16·9, and 19·7 per 1000 in the three preceding weeks, further increased to 20·1 per 1000 during the week ending July 22nd. During the past four weeks the death-rate has averaged 16 9 per 1000, the rates during the same period being 11·9 in London and 15·3 in Edinburgh. The 146 deaths of persons belonging to Dublin registered during the week under notice were three in excess of the number in the eceding week and included 20 which were referred to the incipal infectious diseases, against seven, eight, and 17 the three preceding weeks; of these, 18 resulted om diarrhœa, one from whooping-cough, and one from fever," but none from small-pox, measles, scarlet ver, or diphtheria. These 20 deaths were equal to annual rate of 2 8 per 1000, the death-rates last eek from the principal infectious diseases being 1 5 in ondon and 1·4 in Edinburgh. The fatal cases of diarrhœa, hich had been two, six, and 14 in the three preceding eeks, further rose last week to 18. The 146 deaths in ublin last week included 45 among children under one year age and 30 among persons aged 60 years and upwards; e deaths of infants corresponded exactly with the number the preceding week, while those of elderly persons owed a slight increase. Eight inquest cases and nine aths from violence were registered; and 45, or nearly e-third, of the deaths occurred in public institutions. he causes of 11, or nearly 8 per cent., of the deaths gistered in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

In accordance with the provisions of Her late Majesty's rder in Council of April 1st, 1881, Fleet Surgeon William ogerson White, C B., has been placed on the Retired List, ith permission to assume the rank of Deputy Inspector-eneral of Hospitals and Fleets (dated July 17th, 1905).

Royal Army Medical Corps.

Major C. G. Spencer, from the Curragh, is attached to the oyal Army Medical College. Lieutenant-Colonel F. P. ichols is posted to the Eastern Command to take charge f the Station Hospital and troops at Norwich, vice Major . M. O'Callaghan, who goes to Colchester for duty.

Colonel W. E. Webb retires on retired pay (dated July 22nd, 905). Lieutenant J. Waddell, from half-pay, to be Lieuenant (dated June 23rd, 1905). Lieutenant J. Waddell to e Captain (dated June 23rd, 1905).

Channel Islands Militia.

3rd or South Battalion, Royal Jersey Light Infantry: urgeon-Major A. B. Voisin resigns his commission (dated une 17th, 1905).

Imperial Yeomanry.

The City of London (Rough Riders): Surgeon-Lieutenant . F. M. Clarke resigns his commission (dated July 3rd, 905); Robert Martin McQueen to be Surgeon-Lieutenant dated July 3rd, 1905). Nottinghamshire (South Nottinghamhire Hussars): The announcement of the appointment to a urgeon-Lieutenancy of William Trethowan Rowe, which ppeared in the *London Gazette* of June 6th, 1905, bears date May 22nd, 1905.

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 1st Fifeshire: Supernumerary Surgeon-Captain (Honorary Captain in the Army) J. C. G. Macnab is absorbed into the Establishment (dated July 22nd, 1905). 1st Shropshire and Staffordshire: Surgeon-Major J. P. Massingham is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated July 22nd, 1905). The Highland: Edward Elmslie Brown to be Surgeon-Lieutenant (dated July 2nd, 1905).

Rifle: 4th Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Captain H. Dutch to be Surgeon-Major (dated July 22nd, 1905). 2nd Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Major R. T. C. Robertson to be Surgeon-Lieutenant Colonel (dated July 22nd, 1905). 1st Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Lawrence Campbell Vigor Hardwicke to be Surgeon-Lieutenant (dated July 22nd, 1905).

Royal Army Medical Corps (Volunteers).

Harwich Bearer Company: Major (Surgeon-Major, Army Medical Reserve of Officers) S. S. Hoyland is granted the honorary rank of Lieutenant-Colonel (dated July 22nd, 1905).

Royal Army Medical College.

The *Army and Navy Gazette* of July 22nd contains the following announcement: "Some changes in the *personnel* of the Royal Army Medical College may shortly be expected. We understand that the professor of clinical and military medicine, Colonel K. MacLeod, I.M.S., retired, will vacate the appointment and be succeeded by Colonel David Bruce, C.B., F.R.S., R.A.M.C. Then the professor of military surgery, Surgeon-General W. F. Stevenson, C.B., R.A.M.C., retires at the end of this month and will, in all probability, be succeeded by Major C. G. Spencer, R.A.M.C., whose claims and qualifications stand very high, he being an M.B. Lond. and F.R.C.S. Eng. Further, in January next Lieutenant-Colonel R. H. Firth, R.A.M.C., Professor of Military Hygiene, will vacate his appointment. The selection of his successor lies between Lieutenant-Colonel A. M. Davies, R.A.M C., now expert in sanitation, and member of the Army Medical Service Advisory Board, and Major W. H. Horrocks, R.A.M.C. Both possess high qualifications. It is reported that close on 80 officers of the Royal Army Medical Corps will be required for India and the colonies during the next relief season. Last season about a similar number were also on the foreign roster."

The Volunteers and the late War Office Circular.

It will be remembered that Mr. Arnold-Forster in his recent circular proposed that the men composing the Volunteer forces should be subjected to a medical inspection and examination in order to ascertain the number of those who were fit for service abroad. We now learn from the *Standard* of July 25th that the members of three companies of the 1st Dorset Artillery Volunteers, assembled for gun practice at Portland, "declined to submit to any such examination, the ground taken being that their contract was to make themselves efficient to serve anywhere in the United Kingdom. They were, they declared, efficient and prepared to fulfil their contract, but they held that they were within their right in refusing to submit to a medical examination for foreign service."

The New Naval Hospital at Chatham.

On July 26th the King formally opened the new Royal Naval Hospital at Chatham. The buildings will contain 600 beds with accommodation for 90 members of the staff.

The Health of the Japanese Imperial Navy.

Baron Saneyoshi, Chief of the Bureau of Medical Affairs, in his report on the health of the Japanese Navy for the year 1902, which has just been issued, says: The mean daily force in the service for the year under notice was 30,445 persons, an increase of 3976 in comparison with 26,469 persons of the preceding year. The number of cases of disease and injury reported amounted to, as a result of the expansion of the navy, 25,670, which shows an increase of 716 cases as compared with 24,954 of the preceding year and the number of days' sickness, which is 620,686 days, shows an increase of 35,821 when compared with 584,865 days of the last year. But the ratios of cases of men sick daily per 1000 of force are 843·16 and 55·86 respectively, and the former shows a decrease of 99·60 per 1000 as compared with 942·76 of the previous year, while the latter gives a decrease of 4·68 in comparison with 60·54 of the same year. Such satisfactory results may be regarded as showing a gradual improvement of the health of the navy.

The total number of cases entered under diseases of the urinary and generative systems was 435, which exhibits a ratio of 14·29 per 1000 of force, being a decrease of 2·94 per 1000 as compared with the previous year. There were two cases of deaths, the ratio being 0·07 per 1000 of force, but no case of death occurred in the previous year. Invalidings numbered three, which show a ratio of 0·10 per 1000 of force, being a decrease of 0·05 per 1000 when contrasted with the previous year. The total number of cases comprised under the heading of venereal diseases amounted to 5452, the ratio being 179·08 per 1000 of force, which shows a decrease of 44·80 per 1000 as compared with the last year. Only one case of death occurred but no case appeared in the last year. There were four cases of invalidings, which is in a ratio of 0·13 per 1000 of force, showing a decrease of 0·36 per 1000 as compared with the year before. The venereal diseases are most numerous of all the cases every year and though they show some decrease in this year they still give a ratio of 21·24 per cent. of the total number of all the cases recorded. Arranged according to the number of cases the principal diseases under this heading are as follows: gonorrhœa and its sequelæ, 1985; soft chancre, 1383; bubo, 1027; secondary and tertiary syphilis, 790; and hard chancre, 267.

Correspondence.

"Audi alteram partem."

GRIFFITHS TESTIMONIAL FUND.

To the Editors of THE LANCET.

SIRS,—Allow me on behalf of the wife and family of my brother, the late Dr. A. D. Griffiths of Bridgend, to express our grateful thanks for the practical sympathy shown by the organisers of, and subscribers to, the above fund. I know it was a very great source of comfort to my brother to find so many of our professional brethren coming forward to support him in this time of trial and that the amount realised helped considerably to lighten his load. You also, Sirs, who did so much to forward the fund, I beg to include in our thanks.

I am, Sirs, yours faithfully,
JOHN S. GRIFFITHS.
Bristol, July 26th, 1905.

THE USE OF PHENYLHYDRAZIN IN THE EXAMINATION OF URINE.

To the Editors of THE LANCET.

SIRS,—Apparently Mr. L. C. S. Broughton has not done me the honour of reading my paper carefully, as on p. 17, line 3, I gave the usually accepted melting points of the phenylhydrazin compounds of glycuronic acid which he states in his letter of July 22nd are omitted. My object in the communication I made was not to advocate or to disparage any particular method of performing the phenylhydrazin test but to summarise the advantages and disadvantages of each. Most modern writers on the subject have shown a preference for some modification of the rapid boiling method for clinical work and it is interesting to hear that Mr. Broughton is not in agreement with them.

I am afraid I have not made myself quite clear on another point and that is the part which the physical conditions under which a chemical experiment is performed take in determining its result. The two sentences regarding the rates of osazone formation which Mr. Broughton quotes from my paper and states are contradictory are not so in point of fact, for they refer to two entirely different methods of experimenting and cannot be compared. Similarly it is not justifiable to argue from the rates of osazone formation in simple watery solution to what may be expected under the different physical conditions existing in urine.

I am, Sirs, yours faithfully,
P. J. CAMMIDGE.
July 24th, 1905.

GROCCO'S TRIANGLE IN PLEURAL EFFUSION.

To the Editors of THE LANCET.

SIRS,—As the case mentioned in the concluding paragraph of my paper in THE LANCET of July 22nd might appear to invalidate the statement occurring at the bottom of page 216, which should read as follows after the correction of a slight clerical error:—

> "...... Therefore when a skilled percussor has determined by two or three strokes, and with great accuracy if he should be familiar with the pleximeter, the height of the triangle and the slope of its third side, which is then to be continued from apex to base with a touch of the pencil, *he has not only demonstrated that fluid has gathered in the chest, but also determined its upper level.*[1] ......," &c.—

I would by your courtesy lay stress upon the fact that the triangle in the case in question was, as compared with the ordinary triangle observed in pleural effusions, quite unusually broad, and strictly speaking a *modified* Grocco's triangle, rather than one conforming to Grocco's description.

As cases of this sort, with abdominal dulness rising a slight distance only into the thorax, are of constant occurrence and often difficult to diagnose I may point out that the feature of a Grocco's triangle due to a small intrapleural collection is the smallness of its dimensions and particularly of its base. The coincidence, as in this case, of a dulness confined to the bottom of the chest with a triangle which was very broad and very dull in spite of its shortness might, perhaps, in the future be found to indicate that the cause of the dulness was situated in the abdomen rather than in the thorax.

I am, Sirs, yours faithfully,
WILLIAM EWART.
July 22nd, 1905.

A NEW ELECTRO-CYSTOSCOPE.

To the Editors of THE LANCET.

SIRS,—Referring to an article published in THE LANCET of June 10th, p. 1569, under the heading of "A New Electro-Cystoscope," by William K. Otis, M.D., we wish to make the following remarks. The construction of Dr. Otis's instrument is not new but is generally known. The hemispherical lens is covered by our patents No. 222,384 of March 8th, 1904, and No. 198,437 of April 7th, 1903. We provide cystoscopes with this lens if ordered specially but we make no general use of it as it has not proved so satisfactory as that in the old and well-tried Nitze's system. The other advantages, as claimed for the new instrument by Dr. Otis, are the separate telescope as used in our evacuation cystoscope since 1893 and cold lamps which we have supplied since 1899.

As to the visual field of the Otis cystoscope, we wish to remark that our cystoscopes have, at a distance of four centimetres, a field of 62 millimetres and not of 43 millimetres, as stated by Dr. Otis. It seems to us that Dr. Otis used during his investigations a very old and defective instrument and compared it with his new one. We claim for our cystoscopes that they will give perfectly sharp and clear images. Our instruments would allow, without any difficulty, an enlargement of the field, but in this there would be no advantage, for it is known to every expert that the sharpness of the image suffers by enlargement of the field; in fact, the margins of an extremely enlarged field appear distorted. Square reticulations viewed by the Otis cystoscope will show this distortion clearly, and this makes comparison between objects at the margin and objects in the centre of the field impossible. Ignorance of this fact would mislead observers as to the real appearance of the bladder-wall.

In conclusion we wish to remark that we claim the exclusive right of manufacturing the instrument described. We beg to ask you to insert this letter in the next number of THE LANCET.

We are, Sirs, yours faithfully,
LOUIS & H. LOEWENSTEIN.
28, Ziegelstrasse, Berlin, July 10th, 1905.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Lunacy in Birmingham.

FROM the report of the lunatic asylums committee it appears that whereas on April 1st, 1904, there were 1657 patients in the city asylums, on March 31st, 1905, there were 1701. The annual report by Professor E. B. Whitcombe which is appended contains interesting tables showing the rate of increase of insanity in England generally and in Birmingham particularly—a slow, steady, continuous rise.

---

[1] The italics do not occur in the text.

Other tables show the proportion of cases since 1870 due to drink and heredity. The cases attributed to alcoholism have varied from 7·7 to 27·6 per cent. and those attributed to heredity from 5·3 to 32·8 per cent. He regards sterilisation as the only effective means of coping with the steady increase of the disease.

Birmingham and Cottage Baths.

At the last meeting of the baths subcommittee of the baths and parks committee of the city council it was decided to recommend to the general committee the provision of cottage baths. The scheme is to rent buildings in the most congested districts in which the poor live—probably the experiment will be tried in the Floodgate-street area—and to convert the rooms into cubicles and to provide each cubicle with an ordinary washing and shower bath. The baths are intended primarily for those who cannot be induced to make use of the facilities at the existing public bathing establishments. A nominal uniform charge will be made and, acting upon the suggestion of the chairman of the health committee, it is proposed that the officials of the health department and the lady health visitors should be given a limited number of free admission tickets for those whose circumstances render any payment whatever difficult. Should the experiment prove successful similar baths will be opened in other districts.

The Pollution of the Trent.

Within the last few days an open letter has been addressed to the Earl of Dartmouth, Lord Lieutenant of Staffordshire, by the Duke of Sutherland in which he complains of the pollution of the Trent which has taken place to such a degree that he has been advised that it is unsafe for him and his family to continue to live at Trentham Hall. He also threatens legal action against the Pottery towns, particularly against Stoke, which, in a further letter through his solicitors, he states is making no effort whatever to grapple with the problem, whereas nearly all the other boroughs contributing to the pollution are making efforts to mitigate the nuisance. At Longton £80,000 are being spent on new sewage works, at Burslem £40,000, at Tunstall £10,000, at Wolstanton £7000, and at Fenton £33,500. The corporation of Stoke has spent nearly £50,000 and it contends that the effluent which flows into the Trent really dilutes the foulness of the river rather than pollutes it. It declares that the Trent enters the town in a foul state and the Fowlea Brook in a still more filthy condition. A special meeting of the town council has been called to consider the Duke of Sutherland's letter, but what passed has not yet been published.

July 25th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Graduation Ceremony at the University of Liverpool.

AT a special graduation ceremony held in the senate room of the University on July 22nd the degree of Bachelor of Medicine and Surgery was conferred on the following gentlemen: Charles Harold Smith (first-class honours), Bertram Thomas, Johnson Glover, Richard H. Mole, Courtnay Yorke, and Warrington Yorke (second-class honours). The ordinary degree of Bachelor of Medicine and Surgery was conferred on Robert Cook, John F. Edmiston, Thomas E. Jones, Thomas W. Parry, and Francis H. Storey. The candidates were presented for graduation by Professor B. Moore, the dean of the Medical Faculty, and admitted to degrees by Vice-Chancellor Dale who delivered an address to the newly admitted graduates. The following graduates have been awarded the Diploma in Public Health: A. Critien, M.D., and J. B. Yeoman, M.D., F.R.C.S Edin.

Are Inebriate Homes a Failure?

At a meeting of the Cheshire standing joint committee, held on July 15th, the chief constable presented a report as to the conduct of habitual drunkards who had been liberated from inebriate homes. He stated that since the Act came into operation on Jan. 1st, 1899, 13 persons had been sent to inebriate homes. Of these six had been liberated and they were all women whose ages varied from 34 to 50 years; five of these six were sent to the Bristol home; the other one was sent to a home in Middlesex. Four were sent for a term of three years and two for one year. Detailing the results of the treatment in these homes the chief constable said that one person was as bad as ever and from the day she was liberated she went from bad to worse and died on May 5th, 1904. The second one was now in prison. One person from Altrincham had been seen once under the influence of drink; otherwise she conducted herself well. The detention of a Northwich woman had not reformed her and she craved for intoxicants, as prior to her admission to the home. Dr. Hodgson said that the powers given to the magistrates were inadequate to enable them to reach the curable cases. The incurable cases were practically the only ones that they could reach at present. Practically, it cost £500 to cure one patient and the opinion was expressed that they were wise in Cheshire in not following the example in other counties of building expensive homes for the treatment of inebriates. It seemed to be an absolute waste of money, inasmuch as individuals must be hopeless drunkards before they could be sent to an inebriates' home.

The Select Vestry and the Local Government Board.

At the meeting of the select vestry on July 18th Mr. T. D. Laurence asked whether any reply had been received from the Local Government Board with reference to the agreement between the select vestry and the West Derby guardians as to better accommodation for the epileptic and imbecile poor from the districts of the two boards. The vestry clerk (Mr. H. J. Hagger) said that no reply had been received. He wrote originally on March 22nd and forwarded a copy of the draft agreement to the Local Government Board. Not hearing anything he wrote again on May 7th, mentioning the previous letter and soliciting a reply, but only a bare acknowledgement had been received. Mr. Laurence and Mr. Crosfield expressed the opinion that it was high time the select vestry had a reply.

Lunacy in Lancashire: Increased Accommodation Required.

At Whalley, on July 20th, a Local Government Board inquiry was opened respecting the proposal to erect a new county asylum for Lancashire to accommodate 2000 inmates. A site of 230 acres has been provisionally acquired but the objection urged by local residents, that the site was unsuitable, stopped the scheme in its later stages and led to this inquiry. Mr. Harcourt Clare, the clerk to the Lancashire county council, supporting the application on behalf of the Lancashire asylums board, said that though there were five large asylums with accommodation for nearly 11,000 inmates, there were only about 213 beds at liberty. There were in Lancashire workhouses over 3000 insane paupers, the great majority of whom ought to be in properly managed asylums. There was no asylum in East Lancashire and the board had long felt it desirable to establish one.

Health of Liverpool.

It was reported at the meeting of the health committee on July 20th that during the past week the death-rate of the city was 16·8 per 1000, as against 19·9 per 1000 last year. There were in the city hospitals 485 cases of scarlet fever, eight of typhus fever, 22 of typhoid fever, 34 of measles, and 54 of diphtheria.

Bequests to Liverpool Charities.

By the will of the late Sir John Willox of Liverpool bequests were made to the Liverpool Royal Infirmary, the Royal Southern Hospital, and the Liverpool Stanley Hospital of £10,000 each. £10,000 were also bequeathed to the Liverpool Sanatorium for Consumption at Delamere Forest, to be known as the "Lady Willox Endowment Fund."

July 25th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The West Riding Medical Charitable Society.

THE members of the West Riding Medical Charitable Society, which held its seventy-seventh annual meeting in Leeds on July 22nd, have great reason to be proud of the work which has been accomplished since the society's commencement. The society was started in the year 1828 by 47 medical men of the West Riding who subscribed one guinea each, the sum fixed on as the amount of the annual subscription. Donations from the more affluent members of the profession and from members of the general public were unobtrusively solicited. The motto of the society in its early years seems to have been the wise one of *festina lente*, for a resolution was come to that until the society had accumulated, funds to the amount of £2000 there should be no expenditure by the making of grants. This was achieved in 1837 and in that year the first two grants were made of £15 each, one to the widow of a medical man and the other to a disabled practitioner. From this time the society has carried on its charitable work uninterruptedly from year to year, doing an amount of good which it would be hard to estimate. Its objects are: (1) to aid the widows and children of members dying in indigent circumstances; (2) to aid the sisters of such members, being single women or widows, who have lived with their brothers as housekeepers for a period of not less than five years preceding their death; (3) to aid such members as are wholly or partially disabled by age or permanent bodily infirmities or who are disabled by severe illness from practising for a period of six months; and (4) to aid in the education of the children of members thus incapacitated or temporarily disabled. All applications for relief are most carefully considered and decided on at the annual meeting. This year there were 40 applicants. All these were met by grants varying from £20 to £60 and the society has had the gratification of distributing £1420 in this way, which is the largest amount it has as yet been able to vote. 25 of these grants were made to the widows of medical men, 11 to the children of deceased members, and four to disabled practitioners. When this sum is added to the grants which have been made since the year 1837, the first year the society felt in a position to vote any money, it is found that no less than £40,043 have been given away. The income of the society is derived from the annual subscription of some 730 members, including about a dozen who are not members of the profession, and from its invested funds which are of the nominal value of £30,674 and which yield some £1030 per annum. To the invested funds the general public have contributed about £4300. The prosperous condition of the society depends clearly on the care and economy of its management from its earliest existence. The expenses of management are remarkably low and consist year after year of a small bill for printing and postage amounting to about £20 and a sum of 10*s.* 6*d.* for a copy of the medical directory. There are no incidental expenses. All credit to the late Mr. Garlick who was the first secretary, to the late Dr. Chadwick who succeeded him, to Mr. C. G. Wheelhouse who was appointed joint secretary with Dr. Chadwick in the year 1874, and to Mr. G. H. Rowe who has been associated as co-secretary with Mr. Wheelhouse since the year 1887. The annual meetings give occasion for a pleasant reunion of medical men gathered together for the congenial purposes of distributing grants and dining with each other.

Appointment of Clinical Lecturers in the University.

In order to strengthen the bonds of union which have always been so cordial and intimate between the medical school and the infirmary and in order to give University recognition to members of the staff of the infirmary who may not be on the teaching body in other capacities, it has been decided by the council of the University to institute clinical lectureships on medicine, surgery, gynæcology, ophthalmology, and otology, and that the holders of these posts should have seats on the Faculty of Medicine. In harmony with a recommendation of the Senate that the council should invite those members of the honorary staff who may be recommended by the Senate to the council on a report of the Board of the Faculty of Medicine, and following on such actual recommendations invitations have been issued to members of the staff as follows. As clinical lecturers in medicine:—The honorary physicians: Dr. Thomas Churton, Dr. A. G. Barrs, and Dr. C. M. Chadwick; the honorary physicians with charge of out-patients: Dr. T. Wardrop Griffith and Dr. E. F. Trevelyan. As clinical lecturers in surgery:—The honorary surgeons: Mr. E. Ward, Mr. W. H. Brown, Mr. H. Littlewood, and Mr. R. Lawford Knaggs; the honorary assistant surgeons: Mr. B. G. A. Moynihan and Mr. W. Thompson. As clinical lecturer in gynæcology:—Dr. J. B. Hellier. As clinical lecturers in ophthalmology and otology:—The honorary surgeons of the eye and ear department: Mr. H. Secker Walker and Mr. A. L. Whitehead; the honorary assistant surgeon of the eye and ear department: Mr. G. Constable Hayes. A clinical lectureship in infectious diseases has also been instituted and this has been offered to Mr. A. E. A. Pearson who for many years has held the post of resident medical superintendent of the city hospitals and whose courses of practical instruction have been much appreciated by the students. This clinical lectureship also carries with it a seat on the faculty. As the same time Mr. A. T. Bacon, the instructor in vaccination appointed by the Local Government Board, was elected a member of the Faculty of Medicine.

July 25th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Memorial to the late Dr. William Turnbull.

IT is nearly two years—Sept. 20th, 1903—since the University of Durham College of Medicine lost its popular and faithful demonstrator of anatomy by the death of Dr. Turnbull and his name is now about to be honoured by the establishment of a memorial in the department for which he laboured so long and so earnestly. Shortly after his death a committee was formed, with Sir G. H. Philipson as chairman, to collect funds for this purpose. A little over £100 was raised and at a general meeting of graduates and students held on July 18th it was unanimously decided to erect a brass tablet to his memory in the dissecting room of the college and to found a prize in surface anatomy. Had it been Dr. Turnbull's lot to decide what form any anatomical prize should take he certainly would have selected surface anatomy, for he never tired in his efforts to make his students appreciate the importance of this branch of their studies. The exact details of the scheme have yet to be arranged but it is practically decided that students shall be eligible to compete for the prize at the end of their second winter and that the examination shall be an oral one conducted by the professor of anatomy and his assistant.

Appointment of Demonstrator of Bacteriology at the University of Durham.

Mr. H. J. Hutchens has been selected as the demonstrator of bacteriology at the University of Durham. This is the second time that a St. Bartholomew's man has been appointed to this post, for the late Dr. Bigg also emanated from that school. Mr. Hutchens goes to Newcastle not only with a reputation in his own department but possessing the coveted distinction of Membership of the Distinguished Service Order. He intends to continue his work for the Royal Commission on Tuberculosis.

Heath Scholarship.

The subject for the 1908 essay has just been announced as "Injuries and Diseases of the Arteries, Veins, and Capillaries, and their Treatment." The essay must be typewritten or printed and must reach the professor of surgery not later than March 31st of the year for which it is to be awarded.

Newcastle-upon-Tyne Royal Infirmary.

A new edition of the Hospital Pharmacopœia has just been issued and supplies a long-felt want, for the last edition (1892) has long been out of print. The work has been carried out under the direction of a committee of the medical and surgical staff, assisted by Mr. Sidney Dunstan, F.C.S., M.P.S., head dispenser and teacher of pharmacy to the institution. The result is a very handy and presentable little volume. In addition to the usual information it contains a great deal that will make it a very useful pocket manual for students. The methods commonly used for staining of organisms, examination of urine, preparation of invalid foods, and a table of poisons and their antidotes are useful additions.

July 24th.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Health Report for Cardiff.

IN his recently issued annual report the medical officer of health of Cardiff (Dr. E. Walford) says that the housing accommodation for the working classes is on the whole satisfactory and overcrowding does not exist to any appreciable extent. He defines overcrowding as the occupation of a dwelling with more than two adults to each room counting two children under 12 years of age as equivalent to one adult. Large block tenemental artisans' dwellings do not exist in Cardiff, most of the working-class families occupying separate dwellings with an open space in the front and at the back. Many of these are sublet to single lodgers or to small families but in one or two districts of the town there are many small cottages, in which no lodgers are taken, let at a weekly rental of 5*s.* In June, 1904, an inspection of the town revealed the fact that about 4·4 per cent. of the total number of houses in the borough were unoccupied. The medical officer of health is the executive officer intrusted with the administration of the Midwives Act in Cardiff and he is assisted by a woman sanitary inspector who visits the midwives on the roll in order to explain when necessary the rules of the Central Midwives Board and to enforce compliance with them. There are in Cardiff 96 midwives certified under the Act, of whom 83 were certified on the ground of having been in *bonâ-fide* practice as midwives for at least one year prior to July 31st, 1902, while 12 were certified on the ground of holding the certificate in midwifery of the Obstetrical Society of London and one on the ground of holding the certificate of the Rotunda Hospital, Dublin. The instruction of school teachers in hygiene has already been provided for in Cardiff by the Cardiff College of the University of Wales. Dr. Walford urges the desirability of a routine medical inspection of the schools and scholars in the town for the purpose of ascertaining the cause of absence from school on account of illness of teachers or of pupils, to confer with the head-teachers on the general state of health of the teachers and scholars, more particularly as to the condition of children considered to be physically or mentally weak, to exclude from school attendance children suffering from any communicable disease, and to examine all those known to have been in contact recently with a person suffering from an infectious disease. In former reports Dr. Walford has alluded to difficulties which arise in connexion with the vaccination and revaccination of "contacts" and now suggests that the sanitary authority should undertake the responsibility of securing the vaccination of those who have been exposed to infection. He also advises that some further inducements should be offered to those who submit to the operation for their own and for the public advantage.

Swansea General Hospital.

The board of management of the Swansea General Hospital has usually met with general support for that institution from the inhabitants of the district and in the last annual report it is stated that the hospital debt has been reduced during the past year from £1677 to £1084. The expenditure for the year was £7134 and the income £7882. 1471 patients were treated in the wards at an average cost of £4 17*s.* The convalescent home which was established three years ago in connexion with the hospital has been of great service, for it has taken charge of 130 patients whose earlier discharge from the hospital enabled more acute cases to be treated.

Cardiff Infirmary.

The more detailed report of the Cardiff Infirmary, which has just been issued, records an expenditure during 1904 of £13,131 and an income of £11,477. There were on an average 156 patients in the hospital daily and the average cost per occupied bed was £65, or about 8*s.* less than in the previous year. Among the 2144 patients admitted during the year 1164 were treated in the surgical wards, 303 in the medical, 428 in the ophthalmic, and 249 in the gynæcological. The question of making the out-patients pay for medicines and dressings is now being discussed by a committee of the board of management. The chairman of the board is anxious that some charge should be made and Mr. Lynn Thomas has said that people came in from the out-lying districts for 2*s.* worth of medicine and paid 2*s.* 9*d* in railway fares, while they were quite well able to pay a local practitioner.

Adulteration of Cream of Tartar.

A grocer has recently been fined at the Caerleon police-court £10 and £4 costs for selling cream of tartar adulterated to the extent of 83 per cent., principally with gypsum.

Memorial to the late Dr. T. Gilbart Smith.

A handsome memorial has recently been erected on the highway near Sidmouth, South Devon, to the memory of the late Dr. T. Gilbart Smith. The memorial, which is of blue granite, is in the form of a seat and has the following inscription: "Thomas Gilbart Smith, a succourer of many. Thus closed a noble life spent in the service of his fellow men; he never turned his back on duty, but faithful to his motto, 'dare and do,' remained undaunted to the end. On this spot at half past 9 o'clock after watching the glorious sunset of August 3rd, 1904, Thomas Gilbart Smith, M.D., F.R.C.P., fell dead from his bicycle."

Medical Cricket Match at Bristol.

A cricket match was played on July 20th at the Gloucestershire county cricket ground, Bristol, between teams representing the medical staff of the Bristol Royal Infirmary and Bristol General Hospital and students of the Medical School. There was a large number of spectators present and after an exciting finish the students won by three runs.

July 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Edinburgh.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on July 18th, Dr. J. Playfair, the President, being in the chair. Two gentlemen were admitted to the Fellowship of the College and the Registrar reported that since the last quarterly meeting 24 persons had obtained the Licence of the College by examination. The annual statement by the governing board of the School of Medicine of the Royal Colleges indicated that the number of students during the winter session was 1122 and during the summer session 1237.—The Freeland Barbour Fellowship was awarded to Dr. Benjamin P. Watson and the Hill Pattison-Struthers Bursary in Clinical Medicine to Mr. Robert Murray Fraser.—By vote of the College a Licentiate of the College was expelled from the College and deprived of his Licence to practise, as granted by the College, and of all his rights and privileges as Licentiate.

Graduation Ceremony at the University of Glasgow.

The summer graduation ceremony at the University of Glasgow took place last week. In two cases the degree of M.D. was conferred, while of the 81 graduates who came forward for the degree of M.B., Ch.B., five took the degree "with honours" and 11 "with commendation." At the close of the ceremony Professor Murdoch Cameron delivered a brief address to the graduates. After congratulating them on the completion of their University studies and wishing them God-speed in their work he proceeded to describe the advance which had been made in the science of medicine during the last 50 years. He dealt shortly with the progress in pathology, the discovery of antisepsis and asepsis, and the advancement in hygiene and preventive medicine. In dealing with obstetrics he said: "The idea of progress is intimately associated with the elevation and improvement of the position of women and hence the importance of Queen Margaret College in preparing medical women for zenana work in India. It has been said that the state of the obstetric art in any country may be taken as a measure of the respect of its people for the female sex and this in turn may be taken as a true standard of its civilisation. Prayers for the well-being of such patients have a place in the English liturgy, but I am afraid that in Scotland many in the past have taken but little interest in such cases unless where it concerned their own fireside. I have said in the past, for within the past year there has been a movement which has been well supported. The directors of the maternity hospital are making an appeal for funds for additional buildings which when complete will form a school equipped in all its departments for the teaching of practical obstetrics and gynæcology unequalled in this country. The necessity for this will readily be recognised when it is stated that between 3000 and 4000 women each year take advantage of this hospital in its indoor and outdoor departments. Now in this movement the directors are keeping in view the needs of the University, so that the students, male and female, will have ample opportunities of gaining a thorough practical knowledge under the immediate supervision of the professor of midwifery and the physicians to the hospital. In private practice, in Scotland at least, the illiterate midwife is fast going out of date. In outlying districts the trained nurse holds an important post and forms a useful ally to the overworked country practitioner. Remoter districts in Scotland are being supplied with cottage nurses and the demand in the

Highlands for women holding midwifery certificates is very great owing to the long distances from medical men. It will readily be understood that both rich and poor are alike interested in this work, the importance of which has hitherto never been sufficiently recognised. Outside of students and nurses trained in the Maternity Hospital only those who have been identified with its management have any idea of how quietly the work has been carried on or can form the slightest idea of what a blessing such an institution is to the poor in our populous districts, or how necessary it is for the reception of serious cases which come from the town and country districts of the whole west of Scotland. Building operations have already commenced and it is hoped that before it is finished the directors will be in a position to open it free of debt. Generous donors have already given £40,000 but as much more will be required. It is confidently expected that a generous public will relieve the directors of their financial responsibility. In about two years it should be finished and it is to be hoped that some of you will return to compare notes of the old with the new or become house surgeons and so obtain an experience such as no other hospital can offer. There is a maxim that a large and healthy population is the life and strength of a nation and the source of its strength in art, agriculture, and commerce. Our pride for many years has been our great empire and the aim of our legislators is how to consolidate it. It would be well if they could realise that in our large cities, and even our country towns, there are agencies stealthily at work in the ill-ventilated and overcrowded dwellings which generate disease in one form or other that carry off about one-fourth of the children within the first five years of life. Any careful observer cannot but be impressed with the fact that most of this mortality is due to causes that might be prevented. Diminish intemperance and improve the habits of the people and not only will the death-rate be lessened but mothers will be so improved in health that there will be a disappearance of the antenatal causes that are responsible for the vast number of sickly infants who die before they reach two years of age. We are too apt to look upon such conditions as unavoidable, but if greater care was bestowed upon the mother and her offspring much disease and misery would be prevented. There are very few women who, when married, have much knowledge of children, unless they have had special opportunities of learning, and these form the exception. However highly a woman has been educated she is generally entirely ignorant of maternal duties. Much suffering and injury are the result and this more from ignorance than carelessness. A great agitation is made from time to time about conscription for the safety of our land. It would be wiser to introduce conscription for domestic service amongst girls for the safety, well-being, and happiness of the home. The danger that threatens our country is to be found on the hearth and not on the coast."

The Carnegie Trust for the Universities of Scotland.

The executive committee of the Carnegie Trust has published the list of awards under the research scheme for the year 1905–06. There have been granted in all 16 research fellowships, 28 research scholarships, and 40 research grants, representing an outlay of close on £7000.

July 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Sanitary Condition of Newtownards.

THE medical inspector of the Local Government Board has in a report to his chiefs pointed out that both the water-supply and the drainage of the district are defective. He recommends further that the Newtownards, Bangor urban, and Newtownards rural district council should take into consideration the advisability of providing an infectious diseases hospital, as the workhouse fever hospital is not sufficient for the districts.

Portadown and Banbridge Water supply.

The money required for the carrying out of this scheme—amounting to £70,000 –has all been subscribed, the security to the lenders being the combined rates of both towns.

Maternity Nurses in Derry.

Two of the dispensary medical officers of Derry have urged the Derry Poor-law guardians to appoint two additional maternity nurses for the city district. During the past year the present nurse has attended 215 cases, and in order to give the necessary attention to each case and not to overwork the nurse each nurse should not be asked to attend more than 50 cases in the year. The matter is to be considered fully by the guardians. It is clear that more maternity nurses are urgently required.

Salaries of Dispensary Medical Officers.

Mr. J. F. Mitchell (Bangor) and Dr. R. Henry (Comber) appeared before the Newtownards guardians on July 22nd on behalf of the medical officers of each dispensary district in the union, to ask the guardians to reconsider the question of their salaries. The matter is to come up again for reconsideration in a month.

July 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Spinal Contusions and the Workmen's Compensation Act.

AT a meeting of the Society of Legal Medicine held on July 10th the following case came up for discussion. It was that of a man whose work involved the carrying of large bundles of waste paper. In the course of this employment he bruised his lumbar region and was thereupon afflicted with neuralgia so that he had to take to his bed. Before he was quite well he went back to work and his foot slipping he jarred one of his legs sharply and immediately felt a violent pain in the right groin. The next thing was that his right leg became paralysed, he suffered from pains in the course of the anterior crural nerve, besides exhibiting an anæsthetic patch corresponding to the distribution of the internal saphenous nerve. An action was brought before the Tribunal of Rouen and the court summoned Dr. Laurent to answer the following questions:—1. What is the nature of the injury? 2. Is it of such a kind as to bring about a temporary incapacity for work? 3. What will be the probable duration of such incapacity? Dr. Laurent gave it as his opinion that the man had got traumatic neuritis of the cauda equina and that this had brought on incapacity for work which would last about three or four weeks. The court gave judgment in accordance with Dr. Laurent's evidence. These cases are interesting as they may be diagnosed as hysterical or as cases of simple malingering.

Death Vacancies and the Law.

A trial concerning the above question has recently taken place. The transfer of a medical practice is not legally valid unless the vendor transfers to the buyer negotiable objects such as instruments, books, or furniture coincidently with the transfer of the patients. But the main point for decision in the trial to which I refer was whether such sale is valid when made by the widow or the heirs of the deceased. In this case the widow of a medical man had sold to another medical man her late husband's practice, with the right of occupation of the premises *(cession de location)*. She also sold the books, furniture, and instruments and promised to introduce the buyer to the patients. The buyer, however, refused to execute the contract signed by him, alleging that it was null, and the widow therefore brought an action for damages against him. The Civil Tribunal of Saint-Brieuc, holding that the essentials of the sale of a practice—namely, introduction to the patients and the handing over of patients actually under treatment—could not be carried out by the widow of the practitioner, non-suited her. But the Rennes Court of Appeal reversed this decision, holding that the sale of the practice, together with the sale of books, furniture, and instruments, and the promise of introduction, constituted a transfer of negotiable goods. The court also held that these various elements made up a portion of the patrimony of the deceased and that they could be validly handed over by the widow and the heirs.

Pulmonary Gangrene caused by a Foreign Body in the Bronchus.

At the meeting of the Society of Internal Medicine held on July 3rd M. Fränkel related the case of a man who had come under his care in February and who then exhibited all the signs of a diffuse infiltration of the whole of the lower lobe of the right lung. The patient gave the following history. In August, 1904, he had "swallowed" a small piece of chicken bone, which passed into his respiratory tract. M. Fränkel could not, however, be sure of his diagnosis, for the patient had an anal fistula and his sputum contained Koch's bacilli, so that all the symptoms might have been due to tuberculosis. M. Fränkel asked the patient to submit to bronchoscopy but he refused until some days later when his condition had become desperate. It was then seen that the lung had become gangrenous owing to the foreign body. No intervention was possible for there was no localised focus of disease, the whole lung being riddled with small gangrenous abscesses. The patient died within a few days and M. Fränkel added that he had brought the case to the notice of the society to insist upon the necessity for practising bronchoscopy in all cases of foreign body in the air passages at as early a date as possible. After the foreign body had been imbedded in the air passages for months bronchoscopy was of no avail.

Persistent Hiccough cured by Suggestion.

At the annual meeting of the Society of Hypnology and Psychology, held on June 20th, M. Feuillade related the case of a little girl who, after being frightened, developed a hysterical hiccough which was treated for the space of one month by various means without result. The hiccough persisted during the day but ceased during sleep. The child, whose age was ten and a half years, got very thin and anæmic and refused her food. Her attention was extremely difficult to fix but after the second sitting at which suggestion was practised she ceased to make a noise when she hiccoughed and the only sign of the complaint was a visible and painful contraction of the epigastrium. After the sixteenth sitting, this being the first in which she was really put to sleep, the hiccough ceased entirely. One month later the hiccough returned after the child had been frightened again but a single sitting caused it to disappear.

Pseudo-Appendicitis.

M. de Nittis read a paper on the above subject before the Academy of Medicine on July 12th. He allowed that true appendicitis was far from uncommon but pseudo-appendicitis must also be taken into consideration. The diagnosis of appendicitis was often made under the influence of a kind of preoccupation; cases of floating kidney with pyelitis or of salpingitis were often sent to surgeons as appendicitis, but the reverse mistake hardly ever happened. In the second place—and this was the point upon which he wished to insist—certain affections of the alimentary tract, especially dilatation of the stomach with enteritis, gave exactly the symptoms of appendicitis—even the pain over McBurney's point. In such cases the surgeon might well think that he had to deal with an appendicitis, but in fact the symptoms were due to trouble elsewere, and this trouble could be removed by careful treatment, whereas operation was useless.

The Clinical Examination of Respiratory Chemical Exchange.

At the meeting of the Academy of Medicine, held on July 11th, M. Albert Robin read a most interesting paper upon the above subject. He also showed a simple and ingenious apparatus by means of which, after a little practice, any medical man can easily measure the respiratory coefficient and can, moreover, estimate the respiratory exchange in his patient and thereby deduce a rational method of treatment. A small gauge permits the observer to estimate the inspiratory and expiratory pressures, while by the aid of a three-way cock the expired air can be collected in an indiarubber bag so as easily to be analysed. M. Robin draws the following conclusions from his researches. In cases of very early tuberculosis a marked increase is observed in the figures for the absorption of oxygen and for the elimination of carbon dioxide. A marked decrease in the respiratory exchange is noted in the case of arthritic patients. In the descendants of these two morbid types the same facts may be noted in at least two-thirds of the cases. The above-mentioned types of respiratory exchange will help in distinguishing tuberculous pleurisies (with augmented exchange) from non-tuberculous pleurisies (with diminished or normal exchange). In cases of ascites when the peritoneal cavity is at its maximum of distension the increase in the exchange is very marked, especially from the point of view of carbon dioxide elimination. After tapping the exchange diminishes rapidly in from 24 to 48 hours. In tuberculous cases the best effects of a raw meat diet are seen when the amount given is between 100 and 150 grammes. Above this amount the figure for the carbon dioxide eliminated increases rapidly. The same holds good for eggs if more than from four to six are given. Gelatin if given in doses of 30 grammes per diem rapidly lessens the amount of exchange. Bleeding increases the exchange markedly and is therefore a valuable method of aiding oxidation. Arrhenal given in a dose of five centigrammes per diem diminishes by one quarter the respiratory exchange, but if ten centigrammes are given the exchange is increased by one-tenth. Other arsenical preparations show the same phenomena. The study of the respiratory exchange is thus able to serve as an indication for the dosage of certain drugs.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A New Local Anæsthetic.

Dr. E. Impens of Elberfeld, writing to the *Deutsche Medicinische Wochenschrift*, has given a preliminary account of a new anæsthetic compound termed "alypin." It is the hydrochlorate of benzoyltetramethyldiaminoethyldimethylcarbinol. It is soluble in water, the solutions being of neutral reaction, and it may be sterilised by boiling without prejudice to the anæsthetic action. Alypin is easily absorbed by the mucous membranes and the subcutaneous tissue. The absorption of injected solutions is very prompt and necrotic changes in the neighbourhood of the injection have never been observed. The rapid absorption of the substance favours its anæsthetic action which equals and even excels that of cocaine, as solutions of alypin are efficacious when diluted to a degree at which cocaine becomes inactive. For rabbits a solution of 0·005 per cent. strength produced anæsthesia of the cornea, whilst a solution of cocaine of 0·01 per cent. strength had no effect. In the human eye the administration of a 0·025 solution of alypin produced a decrease of the sensibility of the cornea; with a 0·05 solution the corneal reflex disappeared; and with solutions of a strength from 1 to 2 per cent. complete anæsthesia of the cornea occurred within 60 or 75 seconds. The anæsthesia, like that produced by cocaine, lasts from eight to ten minutes but it differs remarkably from cocaine in this respect, that neither mydriasis nor disturbance of accommodation occurs. The eye, after the anæsthesia has passed off, is in its ordinary condition, not being affected in any way. Moreover, alypin is much less toxic than cocaine, the lethal dose for dogs and cats being twice that of cocaine. With regard to the action of the substance on the respiration and circulation the article states that the small doses which are used in practice have no toxic action; after local application as well as after subcutaneous administration the blood-vessels are dilated, whilst in animals larger doses diminish the blood pressure and the pulse rate. Other physical functions, such as secretion of urine, metabolism, and the body temperature, are not affected at all. Albumin was never observed in the urine. The blood undergoes no modification. Alypin has a slight paralysing action on protoplasm: a solution of 4 per cent. strength applied to a nerve destroys the reaction of the nerve against irritation, whilst the transmission of the nerve impulse is unimpeded. Alypin is excreted through the kidney as the presence of a base may be ascertained in the urine by means of an iodised solution of potassium iodide. The general results obtained by Dr. Impens are to the effect that alypin is an anæsthetic compound of neutral reaction, easily soluble, of the same action as cocaine but without its toxic symptoms, and producing neither mydriasis nor interference with accommodation. It is for these reasons superior also to stovain which has an acid reaction, is not soluble, and is less energetic than cocaine, whilst mydriasis is produced by its administration.

Hygiene of Health Resorts.

A remarkable collective investigation is to be carried out on behalf of the committee of the Berlin Practitioners' Association. Its joint committee (*Geschäftsausschuss der Berliner Standes-Vereine*) at the beginning of the excursion season this year sent to the members of the association a circular in which they were asked to investigate the hygienic condition of any health resort, spa, or other place where they might happen to spend their summer holidays. For that purpose they were provided with a blank form containing queries on the following subjects: number of resident medical men and of pharmacies; condition of the drinking water, condition of the sewers, street cleaning, and fire protection; hospitals (number of beds, wards for infectious diseases), apparatus for disinfection, nursing, and transport of sick, injured, and invalids; first aid; hygienic condition of the baths; hygiene of food, especially of milk; slaughter houses; notification of infectious diseases; and occurrence of epidemics. Undoubtedly the committee is well advised in taking this step, for the hygienic condition of many of the watering places, health resorts, and other summer quarters is far from being satisfactory. It would be injudicious for local practitioners to embroil themselves with the local authorities and they are often unable to improve matters, as their practices would suffer in consequence of persistent attempts at carrying out reforms unwelcome to certain classes of the population. Investigations by independent medical men are therefore advisable.

July 24th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Enuresis.

AT a meeting of the Medical Society of Zürich held on June 24th Dr. Theodore Zangger read a paper on the Treatment of Functional Enuresis. He said that the prevalence of this distressing condition was much greater than was commonly supposed and that the observations of medical officers of schools in combination with those of the teachers in public schools might perhaps supply trustworthy statistics. The little sufferers were for the most part treated injudiciously and harshly or even cruelly by parents, relatives, and teachers. General nervousness was thereby increased in these children who almost all came from a nervous stock and mental disease might even be engendered. Purely medicinal treatment was not very efficacious, belladonna and rhus standing in the foreground. Hygienic and educational methods came first in order of usefulness and faradisation of the bladder has proved most useful, but the treatment must be continued for many weeks or even months and relapses often occurred. Cauterisation of the neck of the bladder or intra-urethral application of faradic currents at the same spot often acted well but as these methods must remain in the hands of specialists any new methods applicable in general practice must be welcomed. Dr. Zangger has been very well satisfied with the results of bimanual massage of the neck of the bladder, one finger working from the rectum. In young children half a dozen applications of massage for a period ranging from three to five minutes once or twice a week were followed by recovery. Dr. Zangger gave full details of five cases of long standing in which all other therapeutic measures had failed, the ages of the patients varying from 11 to 17 years. Massage repeated from 12 to 20 times proved successful in all cases but one, this patient being the subject of serious mental deficiency, and even in this case a great improvement was obtained.

The Treatment of Pseudarthrosis.

A short time ago Professor Bier of Bonn recommended injection of human blood into the neighbourhood of fractures in which bony union could not be obtained and he reported ten cases successfully treated in this way. Dr. Lauper of Interlaken has published a report of two cases, in one of which a woman, aged 71 years, sustained a fracture of the tibia and fibula on Oct. 10th, 1904, and the bones had not united by February, 1905. Dr. Lauper gave injections of 35 or 40 cubic centimetres of blood in the region of the fracture. The blood was obtained by venesection from a healthy man, defibrinated, and injected with antiseptic precautions on Feb. 3rd, 10th, and 17th. Consolidation was noted after eight days; after five weeks the patient could walk about again and has done so ever since. A case occurring in a man, aged 44 years, was treated with injections of the patient's own blood and excellent results were obtained. This operation, therefore, seems deserving of further trial.

Medical Students at the Swiss Universities.

This summer 1679 students were registered at the five Swiss medical faculties—an increase of 146 as compared with the summer of 1904. Only 556 were of Swiss nationality, 1123 being foreigners; as usual, the proportion of females was very large, their actual number being 817. The total numbers at the several universities were as follows: at Basle, 149; at Bern, 554, including 330 females; at Geneva, 285, including 132 females; at Lausanne, 306, including 209 females; and at Zürich, 385, including 165 females.

Zürich, July 24th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Red Cross in the Malarious Districts.

FOR some 12 years the Italian Red Cross has been extending its original sphere of usefulness and now includes in its salutary intervention not only the wounded in war but also the sufferers from disease, endemic or epidemic. In the summer season, for instance, the Roman Campagna is prolific in cases of malarial poisoning and for the treatment of these, as well as by way of prophylaxis, it has established seven "*stazioni sanitarie*" mainly for the purpose of applying quinine, hypodermically and per os, for prevention and cure. In the month of June 8021 individuals came under such treatment, all with results satisfactory on the whole with the exception of 168 persons who either refused to take the quinine prophylactically or who could be prevailed upon to take it only in insufficient quantity. In addition to these there were under Red Cross treatment 115 cases suffering from various non-malarial disorders. Of the patients who had to be conveyed to Rome for further treatment in hospital there were 36, of whom ten were carried by rail and 26 by the ambulances of the Red Cross or, failing these, by the next best vehicles.

The Sixth International Congress of Criminal Anthropology.

The fifth of these Congresses was held in 1901 at Amsterdam and at its close it was moved and carried, *nemine contradicente*, that the sixth should have its seat at Turin. In the Piedmontese capital, accordingly, an organising committee has just been formed to make the necessary arrangements. That committee, on which the local magistracy, the leaders of the medical and juridical faculties, and others of the Senatus Academicus were represented, has decided that the Congress shall take place on April 26th next. The committee came to a further decision—namely, to reinforce its membership with others of the medical and legal professions drawn from the English-speaking world as well as from the continent and to nominate as president his Excellency Signor Bianchi, Minister of Public Instruction, who will open the Congress with an address. In connexion with the Congress there will be an exposition of criminal anthropology which, *inter alia*, will include all the instruments and apparatus for the diagnosis of the physical malformations (craniological and other) favouring or conditioning the tendency to crime, as well as the various means for detecting criminal acts. Further arrangements for the division of the procedure into sections, with the subjects to be dealt with and discussed in each, will be made public at an early date, so as to insure the success of a Congress which bids fair to be not less instructive theoretically and practically than any of its five predecessors.

July 20th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Specialists' Pay for Military Medical Officers.

THE Government of India has issued a notice with reference to specialists' pay for officers of the Royal Army Medical Corps and the Indian Medical Service. This pay is an allowance to officers below the rank of lieutenant-colonel for special sanitary or medical work done for the State which it is not in the power of an ordinary medical officer to perform with the same efficiency as a specialist. It will not be a personal allowance but will be granted only to incumbents of certain specified appointments. Specialists' pay will not be given to officers of the Indian Medical Service in civil employ so that this concession is solely for the benefit of military medical officers. The services of the specialists are to be absolutely at the disposal of the Government in any way that it may direct without further claim for remuneration. The duties of all specialist appointments must be carried out in addition to ordinary hospital duties. The pay of all specialists for this extra work will be the same—viz., Rs.60 a month. Officers of the Royal Army Medical Corps in India will be eligible as specialists under the qualifications laid down by the Army Council for the Royal Army Medical Corps and the eligibility of an officer of the Indian Medical Service will be decided by the Director-General. An officer may qualify as a specialist at any period of his service. There will be 105 appointments in India—55 going to the Royal Army Medical Corps and 50 to the Indian Medical Service officers in military employ. Finally, the order says that selections for appointments will be made under the orders of His Excellency the Commander-in-Chief. It is obvious from these new rules that the status of a specialist is not held in very high esteem and except for the desire of special study there is little inducement for an officer to seek these appointments.

The Declining Plague Mortality.

The figures of plague mortality have ceased for the present to excite much interest. The decline is general and for the week ending June 24th only 4563 deaths were recorded, of which the Punjab returned 3663, the United Provinces 151, Bombay city 112, Bombay province 253, Calcutta 25, Bengal 137, and Burma 93.

Sanitary Report for Assam.

The sanitary report for the province of Assam during the year 1904 shows that the death-rate (25 85) was low and compares very favourably with the average of the previous five years. The birth-rate was 35·5 and exceeded the death-rate in all districts. The registration of both births and deaths, however, is very defective in Assam. It is curious to note that the birth-rate in rural areas is 6 per 1000 higher than that in the towns. The death-rate from cholera among immigrant tea coolies was the lowest on record but is partly explained by the diminished numbers. The curious disease kala-azar seems to be declining but as the diagnosis is so doubtful little reliance can be placed on the published figures and officers deputed to inquire into this disease show that it is more prevalent than appears. It is not now so decidedly epidemic but occurs in chronic and less strongly marked cases or in isolated cases of more acute type. In the tea gardens diarrhœa and dysentery seem to be particularly prevalent and cause a high mortality which is partly attributed to the complete change of diet which the coolies experience on going to Assam. In Sylhet there is a curious custom followed by the Mussulman community of burying their dead within the house compound. This has been stopped at last by the Chief Commissioner using the special powers given to him under the Act of 1897. A Mussulman cemetery has been provided.

The Calcutta Hospitals.

The report on Bengal charitable dispensaries shows that at the Medical College Hospital in Calcutta important additions and improvements have been made, that the antiquated Campbell Hospital is under reconstruction, and that a large scheme for remodelling the Howrah General Hospital has been sanctioned. The number of in-patients has fallen off in Calcutta, notwithstanding the rapid growth of the population, the admissions of men being less than those of 12 years ago. Women, however, go to the hospitals in much larger numbers. The financial figures are extraordinary. The receipts are contributed to the extent of 75 per cent. by Government and Rs.92,877 were paid by patients. Private subscriptions amounted to less than £1000 and it is remarked that the amount contributed by private liberality is deplorably small and the receipts under this head were actually less than they were 20 years previously.

July 7th.

Obituary.

CHARLES HOOPER, M.R.C.S. ENG., L.S.A.,

CONSULTING SURGEON, ROYAL BUCKINGHAMSHIRE HOSPITAL.

Mr. Charles Hooper died at Aylesbury on July 16th at the age of 75 years, after an illness, bravely borne, lasting ten weeks caused by pneumonia complicated with hydrothorax and later with empyema. He was born at Buntingford, where his father, Dr. John Hooper, was in practice. His professional education was obtained in King's College, London, and he took the diplomas of L.S.A. and M.R.C.S. Eng. in 1852 and 1853 respectively. He first went to Aylesbury as house surgeon to the present Royal Buckinghamshire Hospital (then called the Buckinghamshire Infirmary) and soon succeeded to the practice of Mr. Henry Hayward, and at the time of his death had been in private practice for upwards of 50 years. Mr. Hooper always took a keen interest in his profession and was especially attentive to his poorer patients. He held the post of medical officer of health to the Aylesbury urban district council for many years and was for nearly 50 years medical officer for No. 1 District of the Aylesbury union and public vaccinator. For many years he was one of the honorary surgeons to the Royal Buckinghamshire Hospital and was also local secretary to Epsom College, chairman of the Aylesbury division of the South Midland branch of the British Medical Association, and an Associate of the Sanitary Institute. He acted as churchwarden to the parish church for many years; he was also a school manager and trustee of several charities and the oldest Freemason of his lodge. A man of upright character and a very hard worker, never sparing himself, he, in fact, died in harness.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. James Thorburn, formerly professor of therapeutics and pharmacology in Toronto.—Dr. Du Castel of the Academy of Medicine and physician to the hospitals of Paris.—Dr. Michael Krasin, lecturer in surgery in the University of Kazan.—Dr. Alfred Bidder, formerly director of the Britz Hospital, near Berlin, and author of numerous papers on surgical subjects.—Dr. Johann Latschenberger, *privat-docent* in the medical school and professor of physiology in the Veterinary School, Vienna.—Dr. Philipp Schech, extraordinary professor of laryngology with charge of the throat clinic in the University of Munich, at the age of 59 years.—Dr. Friedrich Fischer, of the Strasburg municipal hospitals, after a protracted illness, at the age of 49 years.—Dr. Moussous, formerly professor of clinical midwifery in the University of Bordeaux.

RUSSIAN UNIVERSITY PROFESSORS TO BE ELECTED.—According to the Odessa *Novosti* in the projected new university statutes the principle of election will be the basis of university life. It is proposed that candidates for chairs shall be elected by the existing professors. It is also suggested that those who read treatises to qualify for professorships shall likewise be subject to the ballot of their university colleagues. It is added, however, that, after all, the professors' selection will be subject to the approval of the Government, so that the appearance of liberalism is only an appearance.

AUGUST BANK HOLIDAY ON THE CONTINENT—Cheap tickets available for eight days will be issued to Brussels on August 2nd to 5th, inclusive, and August 7th. Cheap tickets available for seven days will be issued to Liége, for its exhibition, *via* Harwich and Antwerp. Dining and breakfast cars are run between London and Parkeston Quay, Harwich, on the Antwerp service. Passengers leaving London in the evening reach Brussels next morning and Liége at noon after a comfortable night's rest on board the steamer. For visiting the Hague, the Rhine, North and South Germany, and Basle for Switzerland, special facilities are offered *viâ* the Great Eastern Railway Company's Royal British Mail Harwich-Hook of Holland route. A corridor train with vestibule carriages, dining and breakfast cars, is run on the Hook of Holland service between London and Harwich. From the Hook of Holland through carriages and restaurant cars are run in the North and South German express trains to Cologne, Basle, and Berlin, reaching Cologne at noon and Basle and Berlin in the evening. For the convenience of passengers tickets dated in advance can be obtained at the Liverpool-street Station Continental Enquiry Office. The Royal Danish Mail steamers of Det forenede Dampskibs Selskab of Copenhagen will leave Harwich for Esbjerg (on the West coast of Denmark) on August 3rd and 5th, returning on August 8th and 9th. The General Steam Navigation Company's steamers will leave Harwich on August 2nd and 5th for Hamburg, returning on August 6th and 9th.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT LEICESTER.

THE seventy-third annual meeting of the British Medical Association commenced at Leicester on Monday last, July 24th, this being the first occasion on which the Association has met in that town. It is also the first occasion, we believe, on which the Association has found it necessary to commence its formal business on the Monday of assembly instead of on the next day, the large amount of work to be got through by the representatives necessitating the making an earlier start than usual if the programme was to be completed during the week.

A glance at the meeting of Representatives in the Association Hall in Granby-street on Monday afternoon, the floor space of which was covered with small tables with writing materials at which were seated some 150 representatives of branches, all apparently fully absorbed in the business in hand and making notes of the proceedings, furnished a striking contrast between the present-day method of conducting the business of the Association and that which formerly prevailed. The new constitution has in this matter evolved order out of chaos and it is not any longer possible for the clamorous minority to vote over the heads of the less assertive majority—an obvious advantage to the usefulness of the Association and to the furtherance of its legitimate work. That the representatives were not assembled for a "picnic" was evidenced by the many hours' work that they got through, sitting continuously from 2 to 10, with a short interval for dinner.

Leicester is a busy and a thriving town—a fact which is evidenced by the crowded streets and the constant stream of vehicular traffic through them. The noise of the streets is very marked and the greater portion of it is due to the electric trams, the number of cars run being apparently quite in excess of requirements. These start in the early hours of the morning and do not cease running until near midnight and the din caused by them is very wearying, but on the other hand the fact that they are not overcrowded, as London omnibuses and tram-cars so often are, adds greatly to their convenience.

It is not difficult for the stranger to guess what are the chief industries of Leicester, if he did not know them, as on all sides are hosiery and boot factories, with their tall chimneys pouring forth black smoke at intervals.

The population is upwards of 200,000 and the corporation consists of a mayor, 16 aldermen, and 48 councillors. The administration is a striking instance of the municipal acquirement of such undertakings as gas, electric and water supplies, sewage disposal, and tramways. There are excellent open-air spaces provided in Leicester and no less than four sets of public swimming baths exist in the borough, one installation in particular having cost £50,000.

The water-supply is admittedly limited in quantity; in fact, there is grave anxiety about it as the needs of the town so rapidly grow, though in quality it appears to be satisfactory. The public supply is obtained from Charnwood Forest but it is hoped shortly to supplement this by a scheme providing for a supply from the Derwent Valley. The sewage output is dealt with chiefly by surface irrigation but considerable money is being spent on the adoption here and there of bacteriological processes.

The annual exhibition is being held in the Drill Hall and Magazine-square in "the Newarke." The technical and art schools, too, are situated in the Newarke, a kind of square of walls and watch towers, and as the sectional meetings are held there the exhibition is conveniently situated for the members who attended the reading of scientific papers. Adjoining the drill hall is a marquee in which motor-cars are exhibited as well as some sanitary appliances and a few exhibits of a miscellaneous character. The exhibition is on a decidedly smaller scale than last year and on the whole less interesting. Aseptic furniture is, perhaps, the most prominent feature of the exhibition, relatively more space being devoted to this class of exhibit than on previous occasions, although there are several exhibits demonstrating distinct advances in x ray work and high-frequency apparatus. In another column we commence a detailed account of the more important exhibits.

The annual general meeting was held in the hall of the Young Men's Christian Association on Monday, at 2 P.M., Dr. William Collier, the President, being in the chair. The sole business before the meeting was the confirmation of the minutes of the last meeting held at Oxford. These minutes were taken as read and there being no opposition were duly signed by the President. The meeting then adjourned until Tuesday and the representative meeting commenced.

The adjourned general meeting was held at 2 P.M. on Tuesday, when the first business was the installation of the President-elect. The outgoing President, Dr. Collier, after a brief speech in which he referred to the principal events which had occurred in connexion with the Association during the past year, introduced his successor, Mr. George Cooper Franklin, F.R.C.S. Eng. Dr. Collier then retired and Mr. Franklin, the new President, took the chair. A vote of thanks was passed to the retiring President and, in accordance with the usual custom, he was elected a Vice-President of the Association for life. Under By-law 37, which provides that a treasurer shall be elected by the annual general meeting and shall hold office for three years, Dr. Edward Markham Skerritt retired and Dr. H. Radcliffe Crocker was elected treasurer in his place. A vote of thanks was passed to Dr. Skerritt and he was elected a Vice-President for life.

A recommendation of the Council that a sum of £300 should be voted to the office staff superannuation fund was unanimously adopted and after the appointment of the auditors the meeting adjourned until 8.30 P.M.

At the adjourned meeting, which was held in the Royal Opera House, the President being in the chair, the proceedings were opened by the Mayor of Leicester (Mr. Councillor Hilton) offering a welcome to the Association in the name of the corporation of Leicester. Dr. Astley V. Clarke, one of the honorary secretaries of the executive committee, then introduced the guests and the colonial delegates. Among the former were Professor Hartmann, Paris; Professor Bergheim, Vienna; Professor Czermak, New York; Professor Karl Hesse, Würzburg; Dr. Boyd, New York; Dr. L. A. Thomas, Iowa; and Dr. Charles O'Reilly, Toronto. The Colonial delegates were many and came from nearly all parts of the Empire—the West Indies, Ceylon, India, Malaya, China, Canada, Natal, and Australia. The President having received the guests and delegates then said that his next duty was the very pleasant one of presenting to Sir Constantine Holman and to Mr. Andrew Clark the gold medal of the Association. He alluded to Sir Constantine Holman's long term of service to the profession in connexion with the Surrey Medical Benevolent Society and Epsom College, as well as to his work for the Association. In referring to Mr. Andrew Clark, the President recalled the fact that he had just resigned the office of chairman of council. Both recipients of the medal having replied, the President next announced that the Stewart Prize was presented to Mr. W. H. Power, medical officer of the Local Government Board, who was unfortunately prevented from being present. This concluded the business of the adjourned general meeting and the President of the Association then gave his address which will be found at p. 267.

The sections, which were 12 in number this year, were all conveniently located under one roof in the technical schools in the Newarke, to the great advantage of all concerned. It was unfortunate that the representative meeting was still in session on Wednesday morning when the sections were at work, as this duality of business kept many representatives away from the sections. The representatives have certainly worked exceedingly hard this year and there is likely to be an agitation for an "eight-hours day" before the date of the next annual meeting.

Dr. H. W. Langley Browne has been elected chairman of the Council for the ensuing three years in the place of Mr. Andrew Clark, whose term of office has expired. The members of the Council at their meeting on Tuesday expressed their thanks to Mr. Clark for the able manner in which he had presided over their deliberations during his period of office.

A church service has for many years past been a feature of the Association meeting and heretofore it has been called the "*opening*" service and has taken place on the Tuesday morning at about the usual hour for matins in this country. The relegation of the service this year to five o'clock on the Tuesday afternoon rendered it a somewhat meaningless function, and it was not surprising, therefore, that the attendance showed a falling off. The service took place in St. Martin's Church, the Bishop of the recently created diocese of Birmingham (Dr. Gore) being the preacher. So eminent a thinker should have obtained a larger audience for his exposition of the relationship between the clerical and the medical professions. The collection was, as usual, for division between the British Medical Benevolent Fund and Epsom College. A service was also held at the same time at Holy Cross Roman Catholic Church.

At the adjourned general meeting held in the Temperance Hall at 2 P.M. on Wednesday, the President announced that the Council had received an invitation from the Toronto branch of the Association, conveyed by Professor I. H. Cameron, to meet in Toronto next year. The Council recommended that this invitation should be accepted, a view which was adopted by the meeting. The nomination of the President-elect was, subject to the approval of the Toronto branch, left in the hands of the Council. This concluded the business of the meeting and the President then called upon Dr. Henry Maudsley to deliver the Address in Medicine, which will be found at p. 271.

We must again express our thanks to Mr. Guy Elliston, the general secretary of the Association, for much courtesy and help afforded to the representatives of THE LANCET in various directions.

THE SECTIONS.

MEDICINE.

WEDNESDAY, JULY 26TH.

THE section met under the presidency of Dr. FRANK M. POPE and Sir LAUDER BRUNTON (London) opened a discussion on

The Treatment of Sleeplessness and Pain.

He said that it was not very easy to give a correct and complete definition of sleep, so as to differentiate it entirely from the conditions of coma, delirium, active dreaming, and somnambulism. The subject might be roughly said to be insensible to ordinary external stimuli, when these were not too severe. The state depended partly on the condition of the brain cells and partly on the circulation. The brain cells might be kept active and sleep be prevented by stimulants to the brain itself, such as psychical impressions, worry, anxiety, eagerness, and anticipation, very pleasurable and very painful. Pain had probably a double action, increasing the activity both of the cerebral cells and of the circulation through the brain. Excessive heat or cold to the surface might have a similar action, as well as distension of the stomach or intestines by flatulence, or irritation by excessive acidity in the stomach, or irritant substances in the intestines. Both the circulation and the nerve cells might be influenced by leucomaines formed in the body or taken from without, such as the active principles of tea or coffee. The circulation might be stimulated by over-action of the heart through heat, excitement, drugs (such as tobacco), or by high tension in cases of gout. Rigidity of the arteries leading to the brain might also lead to sleeplessness. The treatment consisted in the removal of the cause if possible or in counteracting the abnormal condition either of the brain cells or of the circulation. As special remedies he mentioned small doses of potassium iodide in combination with massage when the carotids were tense, bathing and rubbing the feet in cold water when coldness of the extremities was associated with sleeplessness, warm bathing or sponging when the skin was dry, the administration of from ten to 30 grains of bicarbonate of soda in gastric acidity, emptying a full stomach or replenishing an empty one with warm food, employing wet pack, cold affusion or hot water sponging in fever followed by exposing the imperfectly dried body covered with a "cradle" and sheet over so as to allow a continuous draught. He recommended the avoidance of nerve stimuli resembling the products of nitrogenous waste and suggested lactic acid and urethane. Chloral depressed the heart and lowered tension and was especially useful in cases of high tension. The same was true of all the chlorine substitution products. On the other hand, the sulphur products, with alcohol, sulphonal, trional, and tetronal, were free from this depressing effect. Valerian, also, was useful in reducing restlessness. The sensation of pain had its own seat in the cerebrum, but it was usually excited by peripheral irritation affecting either nerve ends, nerve trunks, or the spinal cord. There were many varieties of pain—burning, shooting, stabbing, grinding, gnawing, &c. The causes might be peripheral or central. Sensibility to pain varied greatly in different people and in the same person at different times. The treatment of pain consisted in removing irritation or lessening sensibility in nerves, spinal cord, or cerebral centre. The methods of doing this were numerous, and included mental impression, mechanical removal of irritation, neutralisation of chemical irritants, and alterations in nerves and nerve centres by drugs, massage, vibration, and electricity. As particular suggestions in the treatment of pain he pointed out that it was better to administer opium or its derivatives in glycerine by the rectum than to trust to its absorption in a full stomach. He suggested bicarbonate of soda solution with laudanum as an efficient application to an aching hollow tooth or even rinsing the mouth with soda solution to neutralise acidity. Opium followed by chloroform inhalation was the best remedy for hepatic colic, and in angina pectoris morphine in combination with amyl nitrite or nitro glycerine. Headache was best treated by salicylate of soda in combination with potassii bromidum taken overnight or early in the morning. Antipyretic drugs such as phenacetin and antipyrin appeared to lessen pain by causing diffusion of impulses in the spinal cord.

Professor CUSHNY contended that the damage from lack of sleep was greater than that from the use of narcotics, which helped, occasionally administered, to break a vicious circle. Unfortunately, their action was uncertain in degree and time and liable to be attended by excitement. Chloral, one of the best, was introduced in 1869 and others of the chlorine class followed, such as isopral and chloretone. They all depressed the heart and just as surgeons had left chloroform for ether so physicians had turned from the chlorine narcotics to those derived from alcohol, such as paraldehyde and amylene, as being safer though less certain in action. Of the urea compounds, urethane was weak and hedonal required a large dose. Veronal was probably the best in 5–15-grain doses. There were obvious objections to the older vegetable hypnotics, opium and morphine, and the belladonna alkaloids were capricious in action and accompanied by objectionable side effects. He preferred to use racemic hyoscine in combination with bromides.

Sir **William Broadbent** (London) recommended that before employing hypnotics an attempt should be made to identify the cause of sleeplessness. Disordered digestion was commonly the cause of awaking during the night, while anxiety prevented the first sleep. Anything displacing a little gas from the stomach gave relief, even water, without going to the extreme of emetics. He thought cold feet were part of a general condition and best remedied by cold affusion and rubbing. In high arterial tension calomel often gave relief and induced sleep even before the bowels acted. The subjects of low tension were sometimes unable to sleep in the horizontal position as the cerebral vessels were unable to contract and to resist the pressure of blood. Chloral was not only dangerous in primary heart affections but also in many pulmonary diseases on account of the cardiac depression.

Dr. **W. Hale White** (London) thought that before attempting to treat insomnia the physician should assure himself of its reality. Patients often fancied or even dreamt they did not sleep. A good test was remembering to have heard the clock strike. The commonest cause was worrying often about quite trivial matters, in which case sleep might be induced by some monotonous repetition. Waking at 3 A.M. might be due to abnormal sensation of hunger, allayed by swallowing anything, even water. Diarrhœa or flatulence was more productive of sleeplessness than constipation, as was also delayed digestion due to fatigue. The insomnia of convalescence passed off as strength improved. Serious diseases which were incurable or which might shortly be recovered from called for narcotics. 10 grains of Dover's powder often did wonders in pneumonia, as did opium in heart disease; on the contrary, in less serious and long-lasting disease, such as tabes dorsalis or neuralgia, there was great risk of inducing a drug habit. People often awoke for want of ventilation, too great heat, noises, or light, which did not call for drugs. He recommended chloralamide, heroin, and paraldehyde.

Dr. **W. Collier** (Oxford) referred much of the present insomnia to over-education, especially in preparing for scholarships, the successful competitors often suffering after the age of 19 years from nervous failure and insomnia. He thought that the occasional employment of narcotics was of value in breaking a vicious circle before the habit of sleeplessness was established.

Dr. **Huchard** (Paris) considered that sleeplessness was not so much due to actual high circulatory tension as its variation in the same individual. The administration of one-tenth of a grain of calomel three times a day was often enough to gradually restore the habit of sleep in cases of high arterial tension, probably dependent on imperfect metabolism. Low blood-pressure could be rapidly raised by strychnine with which small doses of hypnotics otherwise useless often proved effective. Veronal and dormiol were safe and efficient, the former even in doses of three grains.

Dr. **Bertrand Dawson** (London), referring to the treatment of pain, said that what was wanted was a good peripheral anodyne. Cocaine, eucaine, and adrenalin were too transient. Orthoform and anæsthesin were useful as ointment, insufflating or dusting powder, but were insoluble and so inapplicable to the unbroken skin or as hypodermic injection. He recommended aspirin and trional in combination for sleeplessness through pain.

The **President** of the section said that he found paraldehyde useful as a hypnotic in old topers; perhaps it was like what they had been used to.

Dr. **Wilfred J. Hadley** (London) read a paper entitled,

Diagnosis of the Varieties of Pleural Effusion.

These were (1) Septic and inflammatory; (2) tuberculous; (3) mechanical (heart and renal disease); and (4) cancerous. The means of distinction were clinical; culture and inoculation of the fluid; the effect of tuberculin; Jusset's microscopic method and cytodiagnosis. Polymorph cells indicating inflammatory and small lymphocytes tuberculous lesions, while hydrothorax showed only sparse endothelial cells. Jusset's method consisted of artificially digesting a few ounces of the clotted fluid, centrifugalising, and detecting tubercle bacilli in the deposit. By these means from 40 to 70 per cent. of pleural effusion were found to be of tuberculous origin.

Professor **W. Osler** (Oxford) said that a tuberculous pleurisy might be as acute as any other in onset and might complicate rheumatism or pneumonia. It was most important to examine the sputum frequently for bacilli. His cases showed close on 30 per cent. subsequently dying from phthisis.

Dr. **W. B. Ransom** (Nottingham) read a paper on

The Influence of Posture on Breath Sounds.

It was well known that a cardiac murmur might be distinct on the patient lying down but inaudible while he was standing, but this was not so well appreciated in lung disease. He quoted three cases in which crepitation and rhoncus inaudible in the erect posture was quite distinct on the patient lying down, all in the upper lobe of the lung and all due to tubercle as shown by later development. Expiration was prolonged on lying down possibly from difficulty in descent of the diaphragm.

SURGERY.

Wednesday, July 26th.

Sir **Charles B. Ball** (Dublin) presided in this section and in inaugurating the meeting he mentioned that so many papers had been offered to the section that it had been found necessary to ballot for the papers which were to appear on each day. He then called upon Mr. B. G. A. Moynihan (Leeds) to open a discussion on

The Surgical Treatment of Non-malignant Diseases of the Stomach.

Mr. **Moynihan**, in order to facilitate the discussion, had prepared and had had printed a very full account of his cases which formed the material on which his paper was based and this account was distributed amongst the members at the meeting. He pointed out that the records contained in it were made up to a very recent date and great pains had been taken to obtain trustworthy information as to the present condition of the patients on whom he had operated. The non-malignant conditions of the stomach amenable to surgical treatment naturally were divided into four groups. In the first group were cases of perforating gastric and duodenal ulcers. As to the diagnosis of these cases it was very seldom that there need be any hesitation and as to the treatment there was an absolute unanimity that immediate operation was imperative. There were, however, some points which were not yet settled. In the first place is it advisable to excise the ulcer? Mr. Moynihan did not feel at all sure, and he had not been in the habit of doing it, but he was rather inclined to think that excision of the ulcer before suturing of the perforation would be an improvement. In the second place, should lavage of the peritoneum be performed and drainage arranged? In his opinion the need depended entirely on the time that had elapsed at the time of the operation since the perforation occurred. When a case is seen and the operation is performed a short time after the perforation has happened there is no need to wash out the peritoneal cavity or to drain it. When, however, many hours have elapsed and the peritoneum is definitely infected, lavage and drainage are very necessary. In the third place, is it advisable to perform a gastro-enterostomy at the time of closure of the perforation? He thought that in any case seen early it was desirable to do a gastro-enterostomy or Finney's operation at once, as thereby the healing of the ulcer was greatly expedited; but if the case were seen first when a long time had elapsed since the perforation the general condition of the patient would prohibit any extension of the operation. It is especially desirable that a gastro-enterostomy or Finney's operation should be performed when the ulcer is situated near the pylorus or in the duodenum, as thereby any later obstruction to the passage out of the contents of the stomach would be obviated. Fourthly, is it desirable to wash out the stomach? Mr. Moynihan had latterly been in the habit of washing out the stomach with boiled water immediately before and during the operation of closing the perforation and he felt sure that this practice favoured the closing of the ulcer and prevented later leaking. Lastly, he wished to emphasise the fact that really acute ulcer of the stomach does not perforate but in every case of perforation there had been a definite increase of symptoms for some time before the perforation occurred. The second group of cases included those in which there was hæmorrhage from an ulcer of the stomach. This hæmorrhage might come from an acute or a chronic ulcer. It might arise from an acute ulcer; but it is very difficult to define an acute gastric ulcer because erosions might be included, but the hæmorrhage from an acute ulcer was never of any great interest to surgeons, for though it may be alarming it has a natural tendency to cease, and it is very rare for it to recur. In the case of chronic ulcers the hæmorrhage may be insignificant, or if more profuse it may only recur at very long intervals. In such cases there can be no need for immediate operation so far as the hæmorrhage is concerned. Also if, as occurs in some cases, the hæmorrhage is instant and overwhelming there can be no question of operation, for the patient dies before any operation can be performed. There remain therefore those cases in which the hæmorrhage is of some severity and then within 12 or 24 hours it recurs and recurs again, and the intervals decrease and the quantity of blood lost increases. In these cases it is probable that at least 90 per cent. would prove fatal if no operation were performed. In these cases an immediate operation is needed. Hæmorrhage from gastric ulcer nearly always occurs after an exacerbation of symptoms. Into the third group fall those cases where chronic ulcers of the stomach or duodenum persist in spite of treatment. Mr. Moynihan was inclined to think that chronic ulcers of the duodenum often escape diagnosis, though the diagnosis is generally very easy. The symptoms of chronic ulcer of the stomach or of the duodenum are numerous. The time of onset after the taking of food is of distinct value in localising the situation of the ulcer. The nearer the ulcer is to the cardia the shorter the interval between the taking of food and the occurrence of pain. The later the pain the nearer is the ulcer to the pylorus. Cases certainly have been recorded which seem to throw doubt on this rule but in Mr. Moynihan's opinion they are due to the presence of more than one ulcer in the stomach. The situation of the surface tenderness varies and a rough rule may be laid down that the nearer the tender spot is to the ensiform cartilage the nearer the ulcer is to the cardiac orifice and it has been found possible to prophesy more or less certainly the locality of the ulcer from the situation of the tender spot. The direction of the radiation of the pain is also of some value and it may perhaps one day be possible to state with fair exactness not only the situation of the ulcer but the existence of adhesions and their locality. The surgical treatment of chronic gastric and duodenal ulcers is in every way safer than medical treatment. In addition to the risks of hæmorrhage and perforation there is the additional danger of the development of malignant disease. The probability of this is difficult to estimate exactly, but Mr. Moynihan thinks that in 60 per cent. of the cases of gastric carcinoma there is a definite history of the symptoms of gastric ulcer. The prognosis of operation for gastro-enterostomy (excluding the cases where it is performed for perforation or hæmorrhage) is only 3 per cent., but even if it were higher, even as high as 15 per cent., it would be safer to operate than to leave these chronic ulcers to medical treatment. In all cases of chronic ulcer medical treatment should be tried first, unless there are any urgent symptoms calling for operation. The results of the surgical treatment of these chronic ulcers are very satisfactory. The immediate mortality is very low; in Mr. Moynihan's cases it is only 1·15 per cent. and of all his cases there were 80 per cent. of complete recovery from all symptoms. 10 per cent. of his cases were too recent to be included and in about 3 per cent. either a second operation was needed or no real benefit was obtained. Some of the cases which received no benefit were neurasthenic and with a widened experience such cases would not be submitted to operation. It may safely be said that every year the results of the surgical treatment of chronic gastric ulcer are improving. The fourth group contains cases of hour-glass stomach. These are often overlooked and they are probably by no means rare. It is essential that in all operations on the stomach the surgeon should see and handle the whole of the viscus before performing the operation, otherwise a gastro-enterostomy may be performed on the pyloric pouch of an hour-glass stomach. In one case Mr. Moynihan recognised the existence of an hour-glass stomach but failed to see that the stomach was trifid and so the operation failed of its purpose. Even in an ordinary hour-glass stomach there is generally some constriction of the pylorus, so that even if gastro-enterostomy be done on the cardiac pouch the pyloric pouch will fail to empty itself. There are numerous operations for the treatment of hour-glass contraction and the operation will vary with the exact condition present.

Professor ROBERT SAUNDBY (Birmingham) said that according to many surgeons the physician was doomed to extinction. Against the exploratory incision he was inclined specially to speak for it tended to displace diagnosis, and sometimes an exploratory incision meant that the operator was unable or unwilling to apply the ordinary diagnostic methods of the physician. Only too often it happened that a patient saw a physician and was told that no operation was desirable and a little later the same patient saw a surgeon and was told that an operation was imperative. In many cases it was very desirable that the physician and surgeon should meet and discuss the desirability of an operative procedure. He was entirely opposed to a statement contained in Mr. Moynihan's pamphlet where it was said that the surgeon should operate in all cases of chronic inveterate dyspepsia. This might possibly be true if a chronic inveterate gastric ulcer were present, but chronic inveterate dyspepsia might be the result of atonic dyspepsia with neurasthenia, or of exhaustion from child-bearing, or merely even of defective teeth. In cases such as these surgery can do no good and often does harm. The physician sees many cases early and then with suitable treatment they nearly all get well. Professor Saundby had never lost a case of gastric ulcer from hæmorrhage and therefore operation could not be so very necessary. With duodenal ulcer the case was different and in such cases early operation was very desirable but chronic gastric ulcer in many cases he successfully treated by medical means. He could not agree with Mr. Moynihan's estimate of the fatal character of gastric ulcer, for death very rarely occurred while a patient was under medical treatment. He also did not agree that many gastric ulcers went on to malignant disease; at least this was not so in Birmingham where malignant disease was rare; in fact, in 20 years' of hospital practice he did not think he had seen 20 cases of malignant disease of the stomach.

Professor HARTMANN (Paris) gave the statistics of 119 cases in which he had performed gastro-enterostomy. His operation mortality had been constantly diminishing and the mortality would be less even than it was if physicians would invoke the aid of the surgeon at an earlier stage. He always performed the posterior operation and placed the patient in the Trendelenburg position so that no leakage occurred during the operation. He employed two layers of sutures and the line of fixation was long and inclined downwards and to the right. The stomach was attached to the bowel about eight centimetres from the duodeno-jejunal junction. The most frequent complications were pulmonary and in only one case did a vicious circle form. Most of the unsuccessful cases had a nervous element in them. He was of opinion that all cases of stenosis of the pylorus needed treatment whether the narrowing be slight or severe. As to hæmorrhage he operated in all severe cases and in slighter cases when the hæmorrhage was frequently repeated.

Dr. J. M. T. FINNEY (Baltimore) chiefly referred to his form of pyloroplasty. He described the operation which consisted of a gastro-duodenostomy in which the new opening extended upwards into the pylorus. By an ingenious method of applying the sutures the operation was rendered comparatively easy. He mentioned that Scudder of Boston had devised a modification of the operation, employing continuous sutures, and Gould, also of Boston, had employed clamps but essentially the operation was the same. The indications were practically those of gastro-enterostomy. He had employed it 25 times. The chief contra-indication was hypertrophy of the pylorus and Dr. Finney referred to the great difficulty sometimes experienced in diagnosing between this condition and carcinoma and he related two cases in one of which a malignant growth was diagnosed as non-malignant and in the other, a simple hypertrophy of the pylorus, was thought to be carcinomatous. Dense adhesions also were a contra-indication against his operation but they did not render the operation impossible. He described an interesting case in which at the necropsy marked dilatation of the duodenum was found ; the patient died on the sixth day with all the symptoms of vicious circle. Incidentally he remarked that the so-called "vicious circle" was really an intestinal obstruction. Up to the present his operation had been performed 112 times with ten deaths, and as these statistics were drawn from the operations of 12 surgeons it might be concluded that they had a fair idea of the risk of the operation at present.

Mr. C. W. Mansell Moullin (London) considered that diagnosis was the main difficulty and he looked upon an exploratory operation as a failure in diagnosis. The non-malignant forms of gastric disease which were suitable for surgical treatment were perforated gastric ulcer and cases of gastric ulcer in which exacerbations of the symptoms were present. Cases also in which disease had caused definite structural change were suitable for operation. When hæmorrhage was threatening life or was of frequent recurrence an operation should be performed. When hæmorrhage occurred from a definite bleeding spot he was in favour of dealing with the spot itself and not trusting to a gastro-enterostomy which could not be relied on to stop the hæmorrhage. The pain of gastric ulcer was due to dragging on the peritoneum and not to pressure on the ulcerated surface. In chronic ulcer gastro-enterostomy should be performed when the pain and discomfort interfered with the conduct of life. Mr. Mansell Moullin thought that it would be well to excise the ulcer when possible.

Mr. F. S. Eve (London) dealt chiefly with gastroptosis for which he had operated four times. Two cases had been treated with gastropexy and two with gastro-enterostomy. Two of the cases completely recovered and two were benefited. The treatment of hæmorrhage depended chiefly on the diagnosis. Most cases of hæmorrhagic erosions recovered without operation, but chronic ulcer would not. The difficulties of diagnosis were very great.

Mr. W. Bruce Clarke (London) distributed a pamphlet containing the substance of his views on the questions raised by Mr. Moynihan. He thought that the results of perforation depended in great part on the character of the liquid poured out into the stomach. In 13 out of 15 cases examined the liquid was sterile and therefore in most cases he felt that there was no need to clear out the material poured out into the peritoneal cavity. He laid great stress on drainage and in the average case he put in a drainage-tube, inserted a stretch in the ulcer, and merely sponged out as much as possible, and in one case he merely drained, recovery ensuing. If perforation had occurred earlier he put in a drainage-tube and then transfused the patient to the extent of even 15 pints in the 24 hours into the subcutaneous tissue and thus washed out the peritoneal cavity. Rutherford Morison (Newcastle-upon-Tyne) preferred pyloroplasty to gastro-enterostomy. In his opinion it was the best operation for pyloric stricture ; he had had 28 cases and of these 12 were perfectly well. In four the symptoms returned, caused by fresh ulceration, and in all these gastro-enterostomy had been performed with success.

Mr. F. C. Wallis (London) laid stress on the importance of early diagnosis in perforating ulcer, and he pointed out that the injudicious administration of morphine tended to hide the symptoms. He thought it unwise to waste time in hunting for a perforation not easily discoverable, for by opening the stomach the ulcer could easily be found and treated. He referred to one case in which he had successfully performed gastro-enterostomy on a patient 92 years old.

Mr. C. R. B. Keetley (London) thought that the pelvis should be drained in all cases of perforation of the stomach or any other abdominal viscus. Lavage was useful, perhaps, by causing a leucocytosis, but it must not be forgotten that lavage might wash away the leucocytes. He considered that hæmorrhage from an ulcer was due rather to sepsis than to mere irritation or distension. In many cases a simple jejunostomy was the best treatment for gastric hæmorrhage.

Mr. E. Deanesly (Wolverhampton) mentioned that he had in one case diagnosed as perforated gastric ulcer a case of typhoid with acute inflammation of the spleen and in another case diabetic coma simulated a perforated gastric ulcer. He believed that gastro enterostomy relieved a chronic gastric ulcer even when there was no pyloric stenosis.

Mr. Leonard A. Bidwell (London) thought that the anterior operation of gastro-enterostomy was better for cases of greatly dilated stomach and for cases where there was much thickening round the stomach. He objected to pyloroplasty and to Finney's operation that in neither case was the opening in the most dependent part of the stomach.

Mr. A. B. Mitchell (Belfast) never excised the ulcer in perforation and he quoted a case to show that after suture of the ulcer all trace of it might disappear in nine days. He had known cases of gastric ulcer perforate even when no food was being taken by the mouth. Mere suturing of a perforated gastric ulcer is inefficient if an hour-glass contraction is present.

Mr. Moynihan, in reply, mentioned that he had performed Finney's operation in two cases and both did well. He preferred the posterior operation for gastro enterostomy.

Mr. C. A. Leedham Green (Birmingham) read a paper on

Some Further Experiments on the Sterilisation of the Hands

His recent experiments had only served to confirm his belief expressed at the Oxford meeting of the British Medical Association that alcoholic solutions of antiseptics were the most efficacious and that sublimate alcohol was the best of all. Engel had agreed with the great value of alcoholic solutions but he said that sublimin-alcohol was the most powerful. With this view Mr. Leedham-Green's experiments did not agree. A paper was distributed showing graphically the relative efficiency of the different methods of sterilising the hands.

Mr. C. Y. Pearson (Cork) described the results of a series of experiments on the value of his method of sterilising the hands. The method consisted chiefly in washing in soap-and-water for five minutes, then soaking with gauze dipped in an alcoholic solution of biniodide of mercury. Of 20 cases where it was employed nine were absolutely sterile.

Dr. T. G. Atkins (Cork) : 1. Distributed an Account of the After-histories of 20 Cases of Gastro-jejunostomy (reported at the Oxford meeting) for Non-malignant Diseases of the Stomach, showing that most of them had done well. 2. He also read notes of a case of Acute Gangrenous Appendicitis in a boy, aged 13 years. An operation was performed on the second day, though there was no fever. The appendix was found to be gangrenous and improvement occurred for two days but on the fifth day abdominal pain returned and symptoms of acetonæmia appeared. A second operation showed no local cause and the patient died from acute acetonæmia three days later. Dr. Atkins deduced from the case the need for operation in appendicitis as soon as definite symptoms appeared.

STATE MEDICINE.

Wednesday, July 26th.

After some opening remarks by the President (Dr. Philip Boobbyer of Nottingham) on the disabilities of medical officers of health and their amelioration by the formation of an association of representatives of local authorities and sanitary experts, a discussion on

Hospital Isolation

was introduced by Dr. George Wilson (Warwick) who stated that the deductions he would bring forward were the outcome of 32 years' experience. With regard to small-pox isolation, he contended for a special block at the general infectious hospital, and, in his opinion, there was very little risk of the spread of infection. With regard to scarlet fever, he stated that hospital isolation had failed in reducing the incidence and mortality of the disease. He was also sure that it did not cause the presence of the milder form of the infection and was strongly in favour of separate isolation rather than aggregation in large wards.

Dr. T. Whiteside Hime (Bradford) drew attention to the very inadequate knowledge that was possessed concerning the incidence of infectious diseases and of the impossibility of definitely determining what was the real cause of their prevalence at certain periods and their disappearance almost at others.

Dr. J. E. O'Connor (Leicester) believed that until some trustworthy method of locating unnotified cases was evolved hospital isolation must be inefficacious. He would desire to see proper segregation, not aggregation, of scarlet fever cases.

Dr. F. H. Waddy (Sheffield) stated that during the last four years in Sheffield the houses from which patients were removed to hospital were worse off in respect to recurrence of scarlet fever than were those in which patients were treated at home and that he was sure that hospital isolation would have to be regarded as a last resort for those cases which unfortunately could not possibly be treated in their own homes.

Dr. R. S. Marsden (Birkenhead) was prepared to say that hospital isolation, even if it did no more, greatly reduced the amount of suffering and upon that ground alone it was warranted.

Dr. H. Cooper Pattin (Norwich) urged the desirability of true isolation rather than *aggregation* of scarlet fever cases in large wards.

Dr. Spottiswoode Cameron (Leeds) believed that although many suggestive statistics had been put forward it was very important to interpret them rightly.

Dr. W. R. Smith (London) said that the question of the value or otherwise of hospital isolation was not to be answered on mere statistics and an impartial inquiry into the whole subject was needed. He was sure that the importance of "return" cases had been exaggerated.

Dr. E. Haughton (London) alluded to the difficulty there often was in diagnosis.

Mr. J. M. Mackenzie (Kirkby-in-Ashfield) was certain that contact was the real source of infection in scarlet fever.

The President of the section remarked that isolation for small-pox cases appeared to be a settled matter but he felt the need of an inquiry concerning the value of hospital isolation in other infectious cases.

Dr. Wilson then proposed and Dr. C. Killick Millard (Leicester) seconded the following motion which was carried :—

> That as some doubt has arisen in respect to the value of hospital isolation as at present practised as a preventive measure in checking the spread of scarlet fever and diphtheria and in view of the great expenditure of public money which the provision and maintenance of isolation hospitals for these two diseases entails, it is highly desirable that a full and exhaustive inquiry into the whole subject should be carried out with the object of collecting and analysing the large amount of statistical and other evidence now available and that the Local Government Board, as the central authority, be respectfully requested to institute such inquiry.

INDUSTRIAL HYGIENE.

Wednesday, July 25th.

This section was under the presidency of Dr. H. W. Langley Browne (West Bromwich). A discussion on

Physical Deterioration: its Causes and Extent

was opened by Dr. Dawson Williams (London) who produced several tables illustrating a series of observations on the height and weight of boys in primary schools which showed that after the eighth year of age the weight of boys of the artisan classes was very much below the average, this fact being more noticeable in the lowest grade schools. The same remarks applied to the height of boys, though in a less degree. The first striking statement about physical degeneration was made some years ago by Mr. J. Cantlie, who challenged any person to produce a Londoner of the fourth generation. This challenge had never been answered. Dr. Dawson Williams attributed this physical deterioration to various causes, among which he mentioned—improper feeding in infancy; the fact that among the poorer classes mothers worked hard almost up to the time of their confinement; intemperance in fathers, which was said by French authorities to be more injurious to the children than maternal intemperance; and the practice of large numbers of children in London sitting out of doors until midnight which involved a great expenditure of nervous energy. He mentioned that the London Education Committee intended to provide one meal a day for school children, to be cooked by children learning cookery, and suggested, in conclusion, that the medical profession might undertake to collect materials for the further elucidation of the subject.

Mr. William Hall (Leeds) read a paper on

The Influence of Environment upon Physical Development.

He mentioned the recent statement by a distinguished alienist that environment, in which proper food played the most important part, would knock heredity into a cocked hat. Forty years ago Sir William Jenner showed that rickets was due to improper food in infancy. Since then many authorities had pointed out the same fact and now at least 40 per cent. of our poor were rickety and decayed teeth were universal. Fifty years ago the slum mother was much more sober, cleanly, and domestic than she was to-day. She was better nourished herself, always suckled her children, and after weaning them gave them nutritious bone-making food, which she prepared at home. This had all been done away with by our elaborate education system, costing £20,000,000 yearly. Children were now fed on cheap stale food, well seasoned with condiments, which educated them for the love of stimulants in later life and produced also a tendency to scurvy, rickets, and purpura. A little while ago he had examined over 100 adult skeletons in the crypt of Hythe church where they had lain for several centuries. He was struck by the fact that the bones were small but not rickety, the bony palates not much vaulted and the alveolar arches regular, and the teeth that remained were good. It had been said truly that there were hundreds and thousands of our countrymen now living whose skeletons, if preserved, would some day show highly vaulted bony palates, contracted alveolar arches, anterior protrusion of the upper jaws, the remains of unsound teeth, and abundant general signs of rickety bony framework. It was remarkable that Jewish children in the slums were superior to Christian children in physical development, which was due to the fact that the pregnant Jewess was better cared for, that 90 per cent. of the infants were fed on breast-milk, and that during later childhood they were abundantly fed on bone-making material. Eggs and oil, fish, fresh vegetables, and fruit entered largely into their diet. Yet the Jews had not been taught to safeguard their pregnant wives and to nourish their growing children by the instructors in the modern and costly State education which they were told at Oxford was to be at the root of everything. With the aid of friends he had given during the last two years 46,000 meals to poor council school children from the ages of three to 12 years and he had noticed the remarkable improvement in their physical development by the daily use of fresh antiscorbutic food. They had been fed for five days a week, not merely twice a week, as seemed to be thought sufficient by the London County Council.

Professor R. J. Anderson (Queen's College, Galway) remarked that he thought it would be a most important thing to secure a complete anthropometric survey of the whole of the British Isles. He doubted if improper food was the chief cause of physical deterioration, because, in his opinion, food had of late years greatly improved in quality. He thought that the clergy ought to do more than they did at present to improve the condition of the lower orders.

Mr. W. D. Spanton (Leeds) considered that the most prominent causes of physical degeneration were—efforts to rear premature and diseased infants, absurd educational high pressure, cigarette smoking in the younger generation, and late hours at night: in fact, the love of pleasure, and ergophobia in all classes of society. He considered that there was too much cheap philanthropy, that life was made too easy for the young poor, and that by modern educational methods proper parental discipline was rendered almost impossible.

Mrs. F. M. Dickinson Berry, M.D. (London), said that in her opinion children in London schools were not underfed so much as improperly fed, and that they preferred to eat bread and pickles, dried fish, &c., and had to be forced to eat a proper dinner. She quite endorsed Mr. Hall's remarks about Jewish children.

Dr. D. Chalmers Watson (Edinburgh) emphasised the importance of fresh facts being looked for from the standpoint of experimental medicine. He briefly referred to some results obtained in the course of an experimental investigation on diet carried out in the Physiological Laboratory of Edinburgh University, which showed the necessity of an extended investigation along lines calculated to determine the influence of different diets on the structure and functions of different organs and tissues of the body.

Dr. V. H. Rutherford (London) said that he was struck by the attacks which had been made on education and with which he could not agree. He recommended the more general teaching of hygiene and considered that the subject of proper feeding was most important, in which he included the use of alcohol, the abuse of which was a most potent factor in producing physical unfitness. He also urged the appointment of a Minister of Public Health with Cabinet rank.

The President of the section remarked that physical deterioration was often a mere matter of locality. In his district the development of children at the age of 13 years was better than it was 30 years ago but after the age of 13 the reverse was the case. This he attributed to the fact that the feeding of young children was better than it used to be, but after that age feeding was very irregular, and that excessive cigarette smoking and, to a lesser extent, drinking prevailed among the young men, while the young women spent on dress money which ought to be spent on food.

Dr. John Strachan (Dollar, N.B.) then read a paper on

"School Life as a Cause of Physical Degeneracy," and alluded to the undoubted increase of physical degeneracy and insanity in spite of the great improvements in sanitation and hygiene. He considered that this increase was due to high pressure in schools owing to the modern system of payment by results. Even though the admitted evils of the earlier arrangements for working the Education Acts had since been obviated by repeated changes in the code, yet he wished to point out that the men and women of the present day were the survivors of those who had in previous years been subjected to over-pressure and that many of them were the victims of physical deterioration. He considered that the fear of punishment had a very serious effect on the nervous organisation of children and recommended that the employment of either punishment or prizes as applied to brain work at school should be absolutely forbidden.

PSYCHOLOGICAL MEDICINE.

Wednesday, July 26th.

The proceedings commenced with the presidential address delivered by Dr. **Alexander Reid Urquhart** (Perth Asylum) on

The Heredity of Insanity.

A correct adjustment of the organism to the environment, physical, mental, and moral, constituted sanity and health. Statistics formed the basis of our knowledge of heredity, large numbers of observations having to be made to determine the laws which prevailed in the process of hereditary transmission from parent to progeny. Dr. Urquhart referred to the work of Francis Galton and Karl Pearson as affording much new light and then dealt at considerable length with a large and systematic series of genealogical tables collected by him in the last 20 years, illustrating various aspects of the question of the heredity of mental diseases and the neuroses.

A long discussion followed in which the following members took part: Dr. **T. B. Hyslop** (Bethlem Royal Hospital), Dr. **W. Lloyd Andriezen** (London), Dr. **Fletcher Beach** (London), Dr. **Arthur M. Jackson** (Notts County Asylum), Dr. **A. Clapham**, Dr. **A. T. Schofield** (London), Dr. **David Bower** (Gloucester), Dr. **T. Johnstone** (Leeds), Dr. **Robert Jones** (Claybury Asylum), and the **President** of the section who summed up various points and replied to queries.

Dr. **Schofield** then read a paper on the Extension of Psychology in Medicine, in which he urged the importance of the study of the subconscious mind as of the conscious mind in therapeutics and insanity.—The discussion was continued by the **President**, Dr. **Robert Jones**, Dr. **Hyslop**, and Mr. **James Stewart** (Clifton), after which Dr. **Schofield** replied.

A motion proposing that an appeal should be made to the Central Executive Committee to enable the Psychological Section (with the aid of a small fund) to carry out an inquiry into the heredity of mental disease as compared with the hereditary conditions prevailing in the sane population was carried and the meeting was then brought to a close.

OPHTHALMOLOGY.

Wednesday, July 26th.

The proceedings were opened by the **President**, Mr. **George A. Berry** (Edinburgh). Fifty years ago, he said, ophthalmology was revolutionised by such striking and important discoveries that it leapt at once into the front rank of scientific medicine. In recent years advance had been slower and had been confined principally to operative technique in the introduction of antiseptics and local anæsthetics. This comparatively slow advance was not due to there being nothing left to be found out or to the dearth of work and records in the subject, especially in pathological processes; it was rather due to the slowness of discovery in therapeutic measures and the difficulty of developing this work with due critical insight. Yet he believed the signs of the times were hopeful and he looked for the day when in many branches a rational medicine would eliminate a haphazard surgery.

Dr. **A. Bronner** (Bradford) read notes on a case of Slight Myopia in which distressing local and general symptoms were relieved by the use of glasses which were much too strong.

Mr. **E. E. Henderson** (London) gave the results of his researches into the Action of Influence of the size of the Pupil, as produced by eserine or atropine, on the circulation of fluids within the eye.

Mr. **N. Bishop Harman** (London) narrated the results of Electrical Treatment of Trachoma at the Middlesex Hospital. Mr. **C. Devereux Marshall** (London), Mr. **Cyril H. Walker** (Bristol), the **President** of the section, and Colonel **E. F. Drake-Brockman** (London) discussed the paper.

Mr. **Harman** read a paper on False Hay Fever, upon which Mr. **Devereux Marshall**, Dr. **Bronner**, and the **President** of the Section spoke.

Professor **Hess** (Würzburg) showed drawings illustrating Pigment Migration in Cephalopod Eyes.

Dr. **Karl A. Grossmann** (Liverpool) demonstrated by means of lantern slides numerous cases of Lepra Ophthalmica and also read notes on a case of Absence of the Dilator Muscles of the Iris and of Hot-air Cautery for use in Conical Cornea.

Mr. **Cecil E. Shaw** (Belfast) read notes of a case of Amblyopia, apparently toxic, following influenza.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

Wednesday, July 26th.

Dr. **F. W. Bennett** (Leicester) presided and delivered a brief address welcoming members to the section. A discussion on

The Lines of Treatment in Preventing Acute Middle-ear Suppuration from becoming Chronic

was opened by Dr. **W. Milligan** (Manchester) and Dr. **E. B. Waggett** (London). A paper was read on the same subject by Mr. **T. G. Owston**. The discussion was then resumed by Dr. **A. A. Gray** (Glasgow), Dr. **Atwood Thorne** (London), Mr. **T. Mark Hovell** (London), Mr. **R. Lake** (London), Dr. **W. Hill** (London), Mr. **L. A. Lawrence** (London), Dr. **W. Jobson Horne** (London), Dr. **J. Kerr Love** (Glasgow), Dr. **J. Dundas Grant** (London), Dr. **Herbert Tilley** (London), Dr. **J. Middlemass Hunt** (Liverpool). The **President** of the Section summed up the discussion and the openers replied.

Dr. **Gray** read a paper on the Pathological Conditions found in a Case of an Individual who had suffered from Deafness during Life.

Dr. **W. S. Syme** (Glasgow) demonstrated a Pair of Forceps for Operations on the Maxillary Antrum.

NAVY, ARMY, AND AMBULANCE.

Wednesday, July 26th.

Surgeon Lieutenant-Colonel **H. W. Kiallmark** (London) presided and an interesting paper was communicated to the section by Fleet Surgeon **C. M. Beadnell** on Some Dynamical and Hydrodynamical Effects of the Modern Small-bore Bullet, in which it was claimed that the so-called "explosive" effects of the modern bullet were due to sudden enlargement of the "impact area" resulting from a modification either in the form or in the motion of the projectile. Many of the "explosive" phenomena were due to such eccentricities of flight as the various "spinning-top" and "pirouetting" motions of the bullet.

Papers were read by Fleet-Surgeon **O. W. Andrews** on the Arrangements for the Treatment of Wounded in Action; by Fleet-Surgeon **T. Austen** on the Collection and Distribution of Wounded in a Modern Cruiser Engagement; and by Fleet-Surgeon **E. J. Biden** on the Headdress of Certain Ratings in the Navy.

THE ANNUAL EXHIBITION.

The accommodation provided for the annual exhibition at Leicester in the Drill Hall and Magazine-square, The Newarke, was not extensive but the exhibitors found sufficient space for their requirements. Compared with previous occasions the exhibition this year was smaller in scope, though it contained much to interest the medical profession. There were no striking departures in pharmaceutical applications or methods of administration and for the most part the exhibition of drugs was confined to the familiar advances of past years. There were, of course, a few exceptions. As regards the space taken up, special foods and drugs took a quite minor position in favour of surgical appliances, aseptic hospital furniture, and x ray and high-frequency apparatus. The show of motor-cars and accessories again presented little that was of direct interest to the medical man; he might have seen similar exhibits at any ordinary exhibition of motor-cars. The display of sanitary apparatus, if we except sterilising apparatus for hospital use, was restricted practically to disinfectants and filters but here and there were shown one or two examples of improved lavatory appliances.

In reviewing the exhibits we may adhere to the classification adopted in previous years. This year, however, we have thought it best to modify the order in which each section is taken in accordance with its magnitude. We propose, therefore, to take the various sections of the exhibition in the following order: (1) Surgical Instruments and Appliances; (2) Drugs; (3) Foods and Food Products; (4) Sanitary Appliances; (5) Mineral Waters, Beverages, &c.; (6) Publications; and (7) Miscellaneous.

I.—SURGICAL INSTRUMENTS AND APPLIANCES.

The section devoted to surgical instruments and appliances and special hospital fittings appeared on the whole to have a greater interest for the visitors than the other sections. At any rate, there was plenty to see in this section and altogether this class of article was a feature of the exhibition. Amongst makers of instruments and hospital appliances Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, Cavendish-square, London, W., occupied a fairly large share of the space at the disposal of the exhibition committee. They showed operation tables, one of phosphor bronze with Allen and Hanburys' patent mechanism for the Trendelenburg position attached and with hot water containers, douching funnel, and lithotomy stirrups with foot straps; and another provided with adjustable head-rest, the angle of the table being fixed by a sliding clamp. By means of a lever the ball-bearing steel-cupped rubber-tyred castors may be put in or out of action by a simple movement of the lever. Other operation tables were shown of excellent design which offer every convenience for securing satisfactory positions for the subject under operation. There were also shown a phosphor bronze aseptic instrument cabinet with plate glass shelves and bevelled glass door; a new aseptic table constructed to insure perfect cleanliness; a gas trolley carrying nitrous oxide and oxygen cylinders; an aseptic stand made of phosphor bronze for supporting reservoirs containing various lotions; and finally aseptic towel hangers, made again in that excellent material for the purpose, phosphor bronze. A very large assortment of surgical instruments was presented to view by Messrs. S. Maw, Son, and Sons of 7–12, Aldersgate-street, London, E.C. These comprised instruments for operations on the eye, ear, and nose, besides midwifery instruments, elastic gum catheters, and bougies. Attention was also directed at this stall to some sterilising apparatus for instruments and dressings, and to aseptic theatre furniture in German silver. As an example of a local firm exhibiting an excellent selection of surgical instruments and appliances of recent and approved design Messrs. Albert Brown of 3, Bowling Green-street, Leicester, claim mention. Messrs. James Woolley, Sons, and Co. of Victoria Bridge, Manchester, showed a number of novel appliances of interest both to the physician and the surgeon. Amongst these were the Rochester combination steriliser, an effectual and easily controlled apparatus for the purpose; an electrical apparatus by which the current from the main could be used in small lamps for the examination of the throat and nose; and, lastly, an adjustable truss known as the "Boval." The truss is provided with steel springs which are slotted to receive a specially constructed slide, by means of which a pad of any desired shape or size may be attached to a spring. The slide is so constructed that the spring may be expanded or contracted, whilst the pad may be set at almost any angle. Messrs. Croyden and Co., of 55, Wigmore-street, Cavendish-square, London, W., exhibited a number of specially made catheters, bougies, and special appliances for sterilising such instruments. The exhibit also included some illustrations of the "shadowgraph ureteric bougie." Clothing for the insane and a model of a padded room were the principal exhibits of Messrs. Pocock Brothers, of 235, Southwark Bridge-road, London, S.E. The padded room is provided with an aluminium gutter, a self-acting shutter, a protected door-hinge, and a self-acting and automatic door bolt for opening the door at any distance. Messrs. Isaac Chorlton and Co., of Blackfriars-street, Manchester, exhibited a number of special bedsteads, including mechanical beds, maternity beds, and beds for epileptic cases. In particular may be mentioned the surgical bedstead fitted with a self-elevator, a back rest with foot support, a bed table, fracture boards, an extension arrangement of foot-bar, and a telescopic adjustment for raising the foot end. Close by special bedsteads fitted with patent wire mattress were shown by the Longford Wire Company, Limited, of Warrington. Special hospital bedsteads comprise the exhibit of Messrs. John and Joseph Taunton, Limited, of Belgrave Works, Balsall Heath, Birmingham.

Messrs. R. H. Woodland, of 38A, Commercial-road, Eastbourne, Sussex, exhibited the "Eastbourne" invalid chair which presents many advantages where the conveyance of invalids is concerned. An interesting number of invalid and surgical appliances, including bed-pans, and operating and obstetrical cushions, were exhibited by the Seamless Rubber Company, who were represented by Messrs. Howison and Co. of 4, Snow-hill, London, E.C. The well-known Lawson Tait spring bedsteads for all kinds of invalid purposes were exhibited by Messrs. George Gale and Sons, Limited, of Dominion Works, Birmingham. The Dowsing Radiant Heat Company, Limited, of 24, Budge-row, Cannon-street, London, E.C., exhibited their apparatus for treatment by radiant heat and light, while Mr. C M. Holmquist of 57, Edgware-road, London, W., showed his "sunbeam" semi-reclining light bath, an electric vibrator, and a local bath for the radiant treatment of the limb or shoulder. Some recent improvements in surgical instruments were very well exemplified in the excellent assortment shown by Messrs. John Weiss of 387, Oxford-street, London, W., and Messrs. Lynch and Co. of Silver-street, Falcon-square, London, E.C., exhibited a variety of apparatus and appliances, including sterilisers, gynæcological and other operating instruments, as well as electrical and medical batteries. Messrs. Mayer and Meltzer, of 71, Great Portland-street, London, W., showed an excellent collection of surgical instruments, all made in accordance with recent surgical advance. The exhibit included a special operation-table designed by Mr. Stanley Boyd. Space precludes mentioning in detail the very large selection of surgical instruments of recent and approved design which was shown by Messrs. Arnold and Sons of 31, West Smithfield, London, E.C. Some excellent photographs were also shown illustrating the aseptic theatres fitted up by this firm. Messrs. Philip Harris and Co. of Birmingham exhibited their "perfectum" surgery cabinet which, in design, in completeness of equipment, and economy of space, leaves little to be desired. Messrs. T. Holland and Son of 40, South Audley-street, London, W., announced that they have just patented a new kind of support for flat foot. It is an improvement on the "instep arch sock" as regards strength, elasticity, and durability. Mention may also be made of the improved natural-shaped boots made by this firm.

A very interesting and comprehensive collection of hospital appliances was shown by the Holborn Surgical Instrument Company, Limited, of 26, Thavies Inn, Holborn-circus, London, E.C. A feature of the exhibit was a variety of sterilisers, amongst which may be mentioned in particular the Holborn high-pressure steam steriliser working at 250° F. It is not only a trustworthy apparatus for the sterilisation of dressings with dry steam but is compact and easily managed. Amongst the admirable assortment of surgical instruments and accessories shown at the well-arranged stall of Messrs. Down Brothers, Limited, of 21, St. Thomas's-street, London, S.E., were a "first-aid" box for use on motor-cars, an anæsthetic apparatus designed by various well-known chloroform administrators, aneurysm instruments, bullet forceps and probe guide, and other varieties of forceps. The exhibit included new and original designs of aseptic hospital furniture. The exhibit of the Medical Supply Association of 228, Gray's Inn-road, London, W.C., was made attractive by the demonstration of the Gaiffe-d'Arsonval machine for producing the x rays and high-frequency current directly from the electric main without any interrupter. The machine is exceedingly quiet and steady in operation and a very distinct advantage is tha by its means the quantity of current administered to th patient can be measured from day to day. The exhibi included the Gaiffe auto-motor mercury jet interrupte which appeared to us to work very satisfactorily an silently. A compressed air outfit for producing atomisation or vibratory stimulation was shown by Messr Smith and Wade of 20, Baker-street, London, W., as wa also the "Allison" combined examination couch, operating table, and cabinet. Messrs. W. Watson and Son of 313, High Holborn, London, W.C., exhibited a ne high tension transformer for producing x rays and high-frequency currents directly from an alternating current without induction coil or primary interrupter. The apparatus works beautifully steadily with the x ray tube. Orthopædic appliances and artificial legs formed the subject of exhibition at the stall of Messrs. C. A. Hoefftcke, Limited, 21, Woodstock-street, Oxford-street, London, W. The exhibit included an appliance for fractured leg, tuberculous hip and knee-joint, for paralysis, and walking appliances. Messrs. A. de St. Dalmas and Co. of Leicester showed a selection of excellent medical plasters and surgical bandages, while the Liverpool Lint Company of Mark-street Mills, Netherfield-road North, Liverpool, exhibited their surgeons' tow, absorbent cotton wool, and "impermiette" bed sheeting. Antiseptic wood wool tissue was shown by the Sanitary Wood Wool Company, Limited, of 26, Thavies Inn, Holborn-circus, London, E.C., as also were several antiseptic appliances of which wood wool is the basis. Mr. G. H. Zeal, of 82, Turnmill-street, London, E.C., exhibited a number of specially designed clinical thermometers of which the "Repello" was perhaps the most important departure. This thermometer has already been described in our columns and is made with a compressible glass bulb at the top by means of which the mercury column can be restored to its initial level. Messrs. Harry W. Cox, Limited, of 1A, Rosebery-avenue, London, E.C., are well known for the excellence of their apparatus for x rays and high frequency. In the annexe Messrs. Newton and Co. of 3, Fleet-street, London, E.C., exhibited an interesting collection of medical electrical apparatus including Wright's high tension resonance transformer. This transformer can be connected directly to the alternating main current, contact breakers being dispensed with. With the continuous current a small motor converter is necessary. The exhibit included a stereoscope and some microscopes and spectroscopes.

II.—DRUGS.

Continued attention is being given to the improvement of pharmaceutical preparations and while the bases of old formulæ are in the main adhered to the plan of combination in a great number of instances is more subtle, a greater compatibility is aimed at and those new forms of drugs are chosen the effects of which are more satisfactory. As examples may be quoted the tonic formulæ which have replaced the syrups in which the glycerophosphates are substituted for ordinary phosphates and a more suitable vehicle than sugar. The old Blaud pill again is a very different compound from the modern combination of sulphate of iron and carbonate of soda protected by an effectual envelope of sugar or gelatin against the deteriorating influence of the air. Modern exhibitions of drugs are now generally directed to the display of such improvements together with the advances that have been made in organo-therapeutic preparations and are thus of special interest to the practitioner. The drug section at the annual exhibition at Leicester was no exception though the number of the exhibits was comparatively small. As an example of the extension of the manufacturing chemists business to the preparation of biological remedies may be mentioned the firm of Messrs. Parke, Davies, and Co. of 111, Queen Victoria-street, London, E.C. On Stand 76 this firm showed lantern slides illustrating the preparation of serum and vaccines and the physiological testing of drugs, including the effect on the heart and the blood pressure of adrenalin, chloretone, digitalin, digitoxin, digitalis, and digitalone. Beside these there were exhibited medicine cases and chests and a series of elegant pharmaceutical preparations. Messrs. James Woolley, Sons, and Co., Limited, of Victoria-bridge, Manchester, showed, amongst other interesting preparations, two excellent ointments of perfectly uniform consistence—namely, unguentum resorcin co., useful for skin diseases, and unguentum seditavum, a soothing ointment containing zinc oxide and carbolic acid. A very comprehensive exhibit was that of Messrs. Wyleys, Limited, of Coventry, including the heroin compounds and several excellent syrups and liquors. We have already noticed the merits of formolyptol exhibited by Andrus and Andrus of 46, Holborn-viaduct, London, E.C. It is a pleasant, powerful, and yet non-poisonous antiseptic containing active balsamic agents with formaldehyde. The same firm exhibited hemaboloids, which is stated to be an organic combination of iron and the nucleo-proteids. The Bayer Company, Limited, of 19, St. Dunstan's-hill, London, E.C., exhibited a number of new compounds and synthetics. Amongst these may be mentioned in the form of tablets metakalin, a pure, readily soluble preparation of cresol; veronal, a comparatively new hypnotic, saloquinine, an analgesic; mesotan, an external application in rheumatism and aspirin a substitute for the salicylates. The Angier Chemical Company, Limited, of 32, Snow-hill, London, E.C., exhibited specimens of their emulsion of petroleum with hypophosphites. It would appear that petroleum is not absorbed by the system but the hydrocarbon acts as an excellent vehicle, exerting an antiseptic, sedative, and demulcent action on the intestinal membrane. Messrs. Arthur and Co. of Ogle-street, London, W., made once more a point of their bromaurum used in the treatment of neurasthenia. The preparation is regarded as a direct nerve tonic and is said to be remarkable in subduing pain of long standing. A number of new preparations was shown at the stall of Messrs. Burgoyne, Burbidges, and Co. of 12 and 16, Coleman-street, London, E.C. Amongst these were colloidal calomel, "salit," a fluid containing salicylic acid, and novargan, a silver preparation with strong bactericidal properties and used in gonorrhœa. Messrs. Philip Harris and Co., Limited, of Birmingham had a very interesting display of pharmaceutical preparations, including suprarenalin solution, bactericidal soap, pencils of iodoform, and a series of concentrated mixtures compiled from the formulæ of the pharmacopœias of the London hospitals. Besides palatinoids of various animal substances, Messrs. Oppenheimer, Son, and Co., Limited, of 179, Queen Victoria-street, London, E.C., exhibited "metramine" palatinoids. Metramine is described as a purified form of hexamethylenetetramine which is said to be an excellent antiseptic for the genito-urinary tract, splitting up in the urine into formic aldehyde and ammonia and so rendering it both alkaline and antiseptic. There was also exhibited the now well-known vaporiser and aeriser of this firm. Messrs. C. J. Hewlett and Son of 35 to 42, Charlotte-street, London, E.C., exhibited a number of pharmaceutical preparations of decided merit. Such were, for example, their pepsine and bismuth mixture, their bromide compound and a linctus, and their linimentum betulæ co. containing amongst other things the active principle of oleum betulæ and camphor. Besides these there were a number of admirably prepared antiseptic compounds and an emollient cream. We have already drawn the attention of our readers to the milk of magnesia which was exhibited by the Charles H. Phillips Chemical Company of 14, Henrietta-street, Covent-garden, London, W.C. It is, of course, a powerful antacid and does not disengage gas on being neutralised. It is practically tasteless and incidentally is an excellent cleansing agent for the teeth. Local pharmacy was well represented at the stall of Messrs. T. Howard Lloyd and Co., the exhibit including medicine chests and cases, soluble coated pills, and a number of elegant pharmaceutical preparations. Lastly, Messrs. H. and T. Kirby and Co., Limited, of 14, Newman-street, London, W., exhibited the new synthetic aperient purgen besides a selection of tablets of compressed drugs, soft glycerine lozenges, pearl, gelatine, and sugar-coated pills, and some pleasant, besides effective, antiseptic preparations.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in July the following candidates were successful:—

M.D. EXAMINATION.

Medicine.—William Fraser Annand, B.S., University College; Emile Dupont Aubin, B.S., Middlesex Hospital; William Henry Bailey, St. Bartholomew's Hospital; Elizabeth Honor Bone, B.S., London (Royal Free Hospital) School of Medicine for Women; Arthur Bousfield, B.Sc. (University medal), King's College; Archibald Douglas Hamilton, St. Thomas's Hospital; Percival George Harvey, B.S., St. Bartholomew's Hospital; Francis Riley, B.S., Westminster Hospital; and Edward Allan Wilson, B.S., University of Leeds.

Pathology.—Robert Henry Elliot, B.S., St. Bartholomew's Hospital.

Mental Diseases and Psychology.—Christine Mary Murrell, B.S., London (Royal Free Hospital) School of Medicine for Women.

Midwifery and Diseases of Women.—Mildred Mabel Burgess, London (Royal Free Hospital) School of Medicine for Women; Clement Woodthorpe Chaplin, London Hospital; Victor Evelyn Collins, Guy's Hospital; Thomas Henry Harker, St. Bartholomew's Hospital; Carlton Oldfield, B.S., University of Leeds; and Richard Horace Paramore, St. Bartholomew's Hospital.

State Medicine.—Francis Dawson Blandy, Middlesex Hospital and Victoria University; and Harold Tipping, University College and Guy's Hospital.

M.S. EXAMINATION.

Thomas Holmes, M.D. (University Medal), Guy's Hospital.

A meeting of the Faculty of Medicine was held on July 18th, Dr. J. K. Fowler, the dean of the faculty, being in the chair. The chairman announced that Dr. Lauriston E. Shaw had, in consequence of his election to the Senate, resigned the honorary secretaryship of the faculty. A vote of thanks to Dr. Shaw for his services during the past five years having been carried, it was resolved to postpone the election of a successor until the October meeting. A committee on teaching and research in the "advanced" subjects of the curriculum—viz., those subjects studied after passing the intermediate examination—presented an important report. The report contained proposals for the development of research in pathology, pharmacology, and clinical subjects and made suggestions for grouping the lectureships in subjects such as hygiene, forensic medicine, and mental diseases. The report also dealt with the question of securing funds for the support of medical education and the manner in which such funds should be allocated to different institutions and different subjects. In the final section of the report the committee made recommendations as to the periodical inspection by the University of the medical schools and the recognition by the Senate of practical work done by students in the wards and laboratories of the schools as counting towards the results of the final examinations. The report was amended by the faculty and adopted for presentation to the Senate. The faculty approved a report from the board of dentistry upon additional teaching required in London upon comparative odontology, the pathology of the teeth, and the mycology of the mouth. Resolutions were passed indicating the procedure approved by the faculty relating to theses for degrees in medicine and surgery. The regulations proposed by the Board of Advanced Medical Studies for candidates desiring to take the degree of M.D. in tropical medicine were considered and approved.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations in July the following candidates passed in the subjects indicated:—

Surgery.—H. J. Aldous (Section I.), King's College Hospital; and G. M. Seagrove (Section I.), St. Bartholomew's Hospital.

Medicine.—G. N. Biggs (Section I.), St. Thomas's Hospital and Durham; V. H. Blake (Sections I. and II.), St. George's Hospital; J. L. Meynell (Section I.), London Hospital; L. W. Roberts, Middlesex Hospital; L. Sells (Sections I. and II.), St. Thomas's Hospital; and E. W. T. Watts (Sections I. and II.), Royal Free Hospital.

Forensic Medicine.
V. H. Blake, St s Hospital and Durham;
Hospital; L. Sel M. Magill, Royal Free
Royal Free Hospital. ; and E. W. T. Watts,

Midwifery.—E. M. Magill, Royal Free Hospital; O. C. H. L. Moll, Guy's Hospital and Durham; A. R. Paterson, Calcutta; C. A. K. Renshaw, Cambridge; N. A. Stutterheim, Utrecht; E. W. T. Watts, Royal Free Hospital; W. H. Williams, Cambridge and St. Bartholomew's Hospital; and R. M. Wingent, Guy's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—V. H. Blake, A. R. Paterson, C. A. K. Renshaw, L. W. Roberts, and L. Sells.

LONDON SCHOOL OF TROPICAL MEDICINE.—At the examination at the close of the eighteenth session the following were successful:—

J. T. C. Johnson* (colonial service), E. R. Stitt*, D. Mackinnon* (colonial service), F. E. Wood* (colonial service), Miss Commissariat, W. L. M. Goldie (colonial service), J. S. Smith (colonial service), S. G. Allwood, E. V. Croker (colonial service), A. R. Wellington, E. Hopkinson (colonial service), J. T. Waite (colonial service), W. D. Inness (colonial service), N. Beaumont (colonial service), H. G. Waters, and T. E. F. Toovey (colonial service).

* With distinction.

VICTORIA UNIVERSITY OF MANCHESTER.—At the examination for the diploma in Public Health the following were successful:—

G. G. Buckley, O. H. Chapman, C. W Crawshaw, James Howard, and W. C. Rigby.

UNIVERSITY OF LEEDS.—At a Congregation held on July 22nd the degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on the following:—

Robert Garside Dixon, Harold Fearnley, Alfred Gough, George Herbert Hustler, Thomas Edmund Lister, and Frederick Whalley.

The following are notified as having passed the earlier examinations for the same degrees:—

Final examination.—Part I.:
Hackworth, Digby Wrangha uthbert
Second examination.—Part I leed.
Harold Butler, Horace Lanc William
Frobisher, Sydney Milverton Hepworth, Martin
Keswick, Guy Annesley Mitchell, George Colin Henderson Nicol, John Barton Thompson
Bernard Charles Piercey, and Harold Vallow.

First examination.—Whole examination: William Shaw, Reginald Eccles Smith, and John Norman Lonsdale Thoseby. Part I. only: Israel Lewis Sinson.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred:—

Degree of Bachelor of Science (B.Sc.).—Hector Robert Adam, Aberdeen (with special distiuction in chemistry); Agnes Valentine Baxter, M.A., Brechin; and James Alexander Hendry, M.A., Keith.

Degree of Doctor of Medicine (M.D.).—William Johnston Dewar, M.B., C.M., Arbroath (under old regulations); *Francis Grice-Jones, M.B., C.M., Denbigh (under old regulations); †George Grant Macdonald, M.A., M.B., Ch.B., London Hospital; James Thornton Macpherson, M.B., C.M., Manchester (under old regulations); ‡John Stewart Milne, M.A., M.B., Ch.B., Hartlepool; ‡George Mitchell, M.B., Ch.B., Aberdeen; *Herbert Leith Murray, M.B., Ch.B., Dundee; *Alex. Charles Profeit, M.B., C.M., Ballater (under old regulations); and †Alex. Christie Reid, M.A., M.B., Ch.B., B.Sc., Nottingham.

Degree of Master of Surgery (Ch.M.).—†John Alex. Mackenzie, M.A., M.B., Ch.B., Oldham Infirmary.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) (New Ordinances).—James Milner Adams, M.A., Aberdeen; William Campbell, Bucksburn, Aberdeen; Alexander McRobbie Donaldson, Portknockie; Robert Reid Duncan, Bervie; Richard Eager, Winterbourne, Bristol; Francis William Falconer, Aberdeen (passed Final Examination, April, 1905); William Manson Fergusson, Banff; George Johnston Forgie, Longside; Reginald Arthur Forster, Burton-on-Trent; George Hall, M.A., Macduff; Alexander Walker Laing, Manchester; James McIntosh, Aberdeen; James Mackenzie, Aberdeen; Kenneth Mackinnon, Stornoway, Lewis; George Milne, Fyvie, by Oldmeldrum; John Alexander Milne, Portknockie; Harry Ross Neilson, Glass, Huntly; Paul Bernard Roth, Enfield; Robert Fergusson Russell, Aberdeen; James Silver, Gargunnock; Charles Mollyson Smith, Aberdeen; John Herbert Stephen, Fraserburgh; Isaac Frederick Bernhardi de Villiers, French Hoek, South Africa; Frederick Hamilton Welsh, Umtata, Cape Colony; Cristina Wilson, Aberdeen; and Douglas Alexander Wood, Sittingbourne.

Note.—Charles Butchart Gerrard has passed all the examinations but will not graduate until he has attained the necessary age.

Diploma in Public Health.—Donald John Gair Johnston, M.B., Ch.B. Aberd., Inverness; Alexander McRobbie, M.B., Ch.B. Aberd., Aberdeen; and §George Alexander Mavor, M.A., M.B., Ch.B. Aberd., Aberdeen.

* Commendation for thesis. † Honours for thesis
‡ Highest honours for thesis. § With credit.

QUEEN'S COLLEGE, BELFAST.—Among the prizewinners at the class examinations held at the close of the summer session were the following:—

Botany.—William Willis Dalzell Thomson, William Dickey, John James Gilmore, James Stuart Bellas, Albert Victor Craig, and William Hamilton.

Practical Biology.—William Willis Dalzell Thomson, James Stuart Bellas, Samuel Campbell, William Dickey, and Bertram Chiene Letts.

Practical Chemistry.—Senior: John Seymour. Junior: Thomas Hunter Bellas and Alexander Patton.

Chemical Laboratory.—Ormsby William Moore.
es Robert Harvey, Samuel M'Cormac,

Ferguson Shepherd, Charles Robert Harvey, and Samuel M'Cormac.

Practical Pharmacy.—Caroline Joanna Crawford, John Benjamin Crawford, John Blacker Aickin, and Henry Herbert MacWilliam.

Thomas Carnwath, B.A., M.B., has been elected to one of the research scholarships given by H.M. Commissioners of the Exhibition o 1851. The value of the scholarship is £150 per annum.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. Romeo Mongardi of Turin has been recognised as *privat-docent* of Diseases of the Ear and Throat.—*Breslau:* Dr. Garré of Königsberg has been appointed to the Charge of the Surgical Clinic and Dr. F. Sauerbruch has been recognised as *privat-docent* of Surgery.—*Copenhagen:* Dr. O. A. Saunte has been recognised as *privat-docent* of Ophthalmology.—*Freiburg:* Dr. Paul Clemens has been promoted to an Extraordinary Professorship of Internal Medicine.—*Groningen:* Dr. P. C. Romkes has been recognised as *privat-docent* of Gastro-intestinal Diseases.—*Halle:* Dr. Oswald Baumgarten has been recognised as *privat-docent* of Internal Medicine, and Dr. Arthur Menzer, formerly of the Berlin Charité, has also been recognised as *privat-docent* of that subject.—*Königsberg:* Dr. W. Scholtz has been promoted to the Extraordinary Professorship of Dermatology, vacated by the resignation of Dr. Caspary.—*Leipsic:* Dr. Braun has been promoted to an Extraordinary Professorship of Surgery.

LITERARY INTELLIGENCE.—The Oxford University Press announces that the second part of the second supplement to the Index Kewensis will be ready immediately. This supplement covers the period 1896 to 1900. In the original work the genera and species of flowering plants from the time of Linnæus to 1885 were enumerated, and the first supplement carries on the list to 1895.

Royal College of Surgeons in Ireland: Fellowship Examination.—The following candidates having passed the necessary examination have been admitted Fellows of the College: Mr. J. Campbell, L.R.C.P. & S.I., and Mr. W. J. Mullin, M.B., B.Ch. New Zealand.

King's College Hospital—Opening Ceremony.—The next session will commence on Tuesday, Oct. 3rd, when Professor T. Clifford Allbutt will distribute the prizes and give the opening address on Medical Education in London. The address will be given in the large theatre at King's College at 3 P.M. The annual dinner of old students of King's College Hospital will be held at 7 o'clock on the same evening at the Hotel Cecil when Mr. Arthur A. Napper will preside. Tickets may be obtained from the honorary secretaries: Dr. Percy G. Lewis, 22, Manor-road, Folkestone; Major M. Percy Holt, D.S.O., R.A.M.C., King's College Hospital; Dr. J. F. W. Silk, 47, Devonshire-street, Portland-place, London, W.; Mr. Albert Carless, 10, Welbeck-street, London, W.; and Dr. John Charlton Briscoe, 110, Harley-street, London, W.

The Study of Meteorology.—With the object of advancing the general knowledge of meteorology the council of the Meteorological Society has appointed a lecturer who is prepared to deliver lectures on meteorological subjects—e.g.: How to Observe the Weather, Weather Forecasting, Climate, Rainfall, Thunderstorms, Meteorology in Relation to Agriculture, Health, &c. The lectures will be illustrated by lantern slides from a large collection in the possession of the society. Societies and institutions wishing such lectures will be expected to pay a moderate fee and to defray travelling expenses. Lantern slides can also be obtained on hire from the council of the society which is willing to arrange for exhibiting at the gatherings of local scientific societies, institutions, or schools a collection of photographs, drawings, diagrams, and charts illustrating meteorological phenomena, and of various patterns of instruments used for meteorological observations. It will also, if desired, lend and fit up a complete climatological station for exhibition, showing the necessary instruments in position and ready for use. Further particulars can be obtained from the Assistant Secretary, Royal Meteorological Society, 70, Victoria-street, S.W.

University of Oxford: Pathology Endowment Fund.—In connexion with the Fund which has been started with the object of obtaining suitable endowment for the chair of pathology in Oxford, and which already exceeds the sum of £2000, the following address was presented to the University on June 20th by a deputation from the Oxford medical graduates:—

Address to the Chancellor, Masters, and Scholars of the University of Oxford.

We, the undersigned, members of the University of Oxford, feeling the keenest interest in the welfare of medical education at our University, desire to draw your attention to the action which has been taken by a large number of the Oxford graduates in medicine.

We believe that, although Oxford cannot successfully enter into competition with the metropolis and other large centres for the purpose of clinical teaching, the scientific training of the medical student can be most efficiently carried out in the University, and as a part of the curriculum we consider that the scientific aspect of pathology and bacteriology, as distinct from morbid anatomy, should be permanently provided for at Oxford. This object can only be attained by an endowment, which will secure permanent provision for the teachers of pathology, and for the maintenance of the excellent laboratory the University already possesses. In order to promote such endowment, a meeting of Oxford medical graduates was held upon December 20th, 1904, and the following resolution was passed: "That with a view to showing the strong feeling the Oxford medical graduates have of the necessity for promoting the study and teaching of pathology, a fund be started for the purpose of assisting in this object, and that it be primarily for the establishment and endowment of a professorship in pathology." In accordance with this resolution a "Pathology Endowment Fund" has been started.—We have the honour to be,

Your obedient Servants,
W. S. Church, M.A., D.M., Hon. D.Sc.,
Chairman of Executive Committee.

Followed by the names of 164 Oxford medical graduates.

BOOKS, ETC., RECEIVED.

International Journal of Surgery Co., 100, William street, New York.

The Surgical Assistant. A Manual for Students, Practitioners, Hospital Internes, and Nurses. By Walter M. Brickner, B.S., M.D., New York City. Price $2.00.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The University of Sheffield and its Representation on the General Medical Council.

An amendment has been made in the Sheffield University Bill to provide that the fees for attendance and the travelling expenses of a member payable under section 12 of the Medical Act, 1858, shall not be paid from the funds of the General Medical Council or of the Branch Council for England until such time as, upon the representation of the General Medical Council or of the Privy Council, made in the manner set forth in sections 10 and 19 of the Medical Act, 1886, and subject to the provisions therein contained, His Majesty may by order in Council appoint.

HOUSE OF LORDS.

Thursday, July 20th.

Physical Deterioration.

A long debate on this subject took place on the initiative of the Bishop of Ripon and the Duke of Devonshire. The right reverend prelate called for further inquiry on the subject of infant mortality and the Duke of Devonshire suggested an anthropometric survey with a view to the collection of definite data bearing upon the physical condition of the population as recommended in the report of the Committee on Physical Deterioration.—On behalf of the Government the Marquis of Lansdowne repudiated the imputation of indifference in regard to the matter and stated that the whole question would be further inquired into by a Royal Commission.

HOUSE OF COMMONS.

Wednesday, July 19th.

Diphtheria in Poor-law Schools.

Sir Walter Foster asked the President of the Local Government Board whether, in view of the outbreak of diphtheria at the Norwood Poor-law schools which had extended to 61 children, notwithstanding the care and skill taken for its prevention, he would consider the advisability of breaking up this aggregation of 500 children in accordance with the recommendations of the departmental committee's report of 1897.—Mr. Gerald Balfour answered: It appears to be doubtful whether there can properly be said to have been an outbreak of diphtheria at these schools in the sense in which that expression is ordinarily understood. I am informed that only three of the cases presented the ordinary clinical symptoms of the disease and that in the remaining cases there had been no disturbance of the children's health, although the bacillus of diphtheria or some other bacillus resembling it had been discovered by bacteriological methods. It does not seem to be necessary to consider the advisability of breaking up the school.

Tuberculosis.

Mr. Morrell asked the President of the Board of Agriculture whether the Royal Commission on Tuberculosis had reported, or would shortly report, on the effect produced, or disease set up, by introducing into the body of the bovine animal material containing living tubercle bacilli of human and bovine origin respectively through the alimentary canal as distinct from the effect when introduced by subcutaneous injection and whether he would urge an early report on the third clause of the reference, viz., under what conditions, if at all, the transmission of the disease from animals to man took place and what were the circumstances favourable or unfavourable to such transmission as affecting food for man.—Mr. Gerald Balfour answered: As I stated in my reply to the honourable Member for the Eastern division
understand that the Royal Commission
report towards the end of the present
report will contain details of the differ
methods of infecting bovine and other animals with tube
from different sources, but I understand that some considerable time
must elapse before the Commission can issue a report dealing with the
third clause of the reference to it.

Thursday, July 20th.

Missing State Papers.

Mr. MacVeagh asked the Secretary of State for the Colonies whether his attention had been called to the statement of Sir Fleetwood Wilson at the War Stores Commission to the effect that the cause of the disappearance of the missing papers was that a rat got into the store in which the papers were kept, and that the medical officer ordered the destruction of the papers in order to prevent a plague; whether the medical officer's report was verbal or written; and whether he could communicate the details to the House.—Mr. LYTTELTON replied: The details in connexion with the matter referred to have already been communicated to the House in reply to a question put by the honourable Member for South Donegal on Feb. 8th, 1904, to which I have nothing to add.

The Nursing of the Sick Poor in Workhouses.

Mr. TALBOT asked the President of the Local Government Board whether his attention had been drawn to the condition of the nursing of the sick poor in the workhouses, especially in those which contained only a small number of such inmates; what action had been taken in accordance with the recommendations of the departmental committee which reported on this subject in November, 1902; and whether he could give an assurance that early steps would be taken to carry out those recommendations.—Mr. GERALD BALFOUR answered: After the report of the departmental committee was issued a considerable number of representations were received by the department in connexion with the recommendations of the committee and an order dealing with the subject is in preparation.

Malta Fever.

Mr. YERBURGH asked the Secretary to the Admiralty whether he would state the number of men invalided from Malta fever annually for the ten years from 1895 to 1905 and whether any medical inquiry into the cause of Malta fever had been instituted.—Mr. PRETYMAN answered: A committee, including representatives of the Navy, Army, and Colonial services, has been making inquiry since June, 1904, into the causation and life-history of Malta fever, under the directions and auspices of the Royal Society. Much valuable information has been gained and has been published in interim reports which hold out strong hopes of this fever being in the future more successfully grappled with than in the past. The number of men invalided is as follows:—

Year.	Number of invalids.	Year.	Number of invalids.
1897*	191	1902	250
1898	149	1903	209
1899	68	1904	191
1900	188	1905	(return not yet complete).
1901	163		

* First year in which Mediterranean fever was shown in the reports as a distinct heading.

Vaccination Defaulters in Scotland.

Mr. WEIR asked the Lord Advocate whether he would state the number of prosecutions of vaccination defaulters in Scotland during the current year and for each of the last five years.—The LORD ADVOCATE replied: The information which would enable me to answer the first part of the hon. Member's question is not yet procurable. The prosecutions for the five years ended June 30th, 1904, are—for 1900, 59; for 1901, 103; for 1902, 56; for 1903, 82; and for 1904, 73.

TUESDAY, JULY 25TH.

Small-pox in Belfast.

Mr. JOSEPH DEVLIN asked the Chief Secretary for Ireland whether he was aware that a recrudescence of small-pox was threatened in Belfast and that the corporation refused, contrary to the especial custom, to supply its aid to the ratepayers except where an outbreak occurred in an applicant's house or where an order from a medical man or inspector was presented; and whether he would in the interest of the health of the city cause representations to be made to the corporation in this matter.—Mr. LONG answered: A case of small-pox occurred in Belfast on June 23rd and the Local Government Board is informed that all necessary precautions to prevent the spread of the disease have been taken. The patient was removed to the small-pox hospital and the other inmates to the reception house for isolation, the house was disinfected, the bedding, &c., burned, and revaccination freely administered in the neighbourhood. No further case has been reported. The Board has no information that the corporation has refused to take necessary measures for the protection of the public health.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BREWER, ALEC H., M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Samaritan Free Hospital for Women.

EARLY, R. A., L.S.A. Lond., has been appointed Medical Officer and Public Vaccinator for the Weston-super-Mare District of the Axbridge Union.

FRAMPTON, TREVETHAN, F.R.C.P., M.R.C.S., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

HANCOCK, W. J., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Stalybridge District of the county of Chester.

HILL, R. A. L., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Wimbledon District of the county of Surrey.

LAPAGE, C. P., M.D. Vict., has been appointed Medical Officer to the Out-patient Department of the Manchester Children's Hospital.

MCGAVIN, LAWRIE H., F.R.C.S. Eng., has been appointed Surgeon to the In-patients on the Staff of the *Dreadnought* Hospital, Greenwich.

PATERSON, MARCUS S., M.B., B.S., M.R.C.S., L.R.C.P., has been appointed Medical Superintendent of the Brompton Hospital Sanatorium, Frimley, Surrey.

SWAINSON, G. M. G., F.R.C.S., has been appointed Assistant Surgeon to the North-Eastern Hospital for Children, Hackney-road.

THOMAS, L. KIRBY, M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Birmingham and Midland Hospital for Women.

TYLECOTE, FRANK EDWARD, M.D. Vict., has been appointed Medical Registrar to the Manchester Royal Infirmary.

WESTERMAN, ARTHUR, M.D. Aberd., has been appointed Medical Officer to the City of London and East London Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALDERSHOT URBAN DISTRICT COUNCIL.—Medical Officer of Health and Superintendent of the Isolation Hospital. Salary £300 per annum (being £275 as Medical Officer of Health and £25 as Medical Superintendent of the Isolation Hospital, &c.)

BATH ROYAL UNITED HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing.

BIRKENHEAD BOROUGH HOSPITAL.—Senior and Junior Resident House Surgeons. Salaries £100 and £80 respectively, with fees.

BOURNEMOUTH, ROYAL VICTORIA HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging.

BRISTOL ROYAL INFIRMARY.—Resident Junior House Surgeon and Anæsthetist. Also Resident Casualty Officer. Salary at the rate of £50 per annum, with board, lodging, and washing.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

DOUGLAS, ISLE OF MAN, NOBLE'S ISLE OF MAN HOSPITAL AND DISPENSARY.—Resident House Surgeon, unmarried. Salary £90 a year, with board and washing.

EDINBURGH, UNIVERSITY OF.—Professor of Midwifery.

LANCASTER, ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

LEICESTER INFIRMARY.—Two Assistant House Surgeons for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

LONDON LOCK HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

MACCLESFIELD, CHESHIRE COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £140, rising to £160, with apartments, board, and washing.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer. Salary at rate of £60 per annum, with board, residence, and washing.

ROXBURGH DISTRICT ASYLUM, Melrose, N.B.—Assistant Medical Officer. Salary £140 per annum, with board, rooms, &c.

ST. MARK'S HOSPITAL FOR FISTULA, &c., City-road, E.C.—Junior Anæsthetist. Salary £25 per annum.

ST. MARYLEBONE, PARISH OF.—District Medical Officer. Salary commencing £90 per annum.

SALOP INFIRMARY, Shrewsbury.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

SHEFFIELD ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £65 per annum, with board, lodging, and washing. Also Junior House Physician. Salary £60 per annum, with board, lodging, and washing.

STRAITS SETTLEMENT, MUNICIPALITY OF THE TOWN OF SINGAPORE.—Assistant Municipal Health Officer, unmarried. Salary £400 per annum.

YORKSHIRE, WEST RIDING COUNTY COUNCIL.—Assistant to County Medical Officer. Salary £250 per annum, rising to £400.

Births, Marriages, and Deaths.

BIRTHS.

ANDERSON.—At Pitlochrie, Perthshire, on July 23rd, the wife of John Anderson, M.B. & C.M. Edin., of a daughter.

GIBSON.—On July 24th, at 6, College-terrace, Hampstead, N.W., the wife of H. W. Gibson, M.B., of a son.

WATSON.—On July 20th, at the Oriel House, Leigh, Essex, the wife of W. Douglas Watson, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

YOUNG.—At The Glebe, Hamilton, on July 21st, the wife of J. Murray Young, M.B., of a son.

MARRIAGES.

DIXON—BOKENHAM.—On July 19th, at the parish church, St. Mary's, Hanwell, George Edwin Dixon, M.D., to Marie K. H. Bokenham, eldest daughter of William Henry Bokenham of St. Vincent Lodge, Hanwell, Middlesex.

FOULKES—FISCHER.—On July 20th, at the Portsea parish church, Captain Thomas Howard Foulkes, F.R.C.S., Indian Medical Service, to Bertha, second daughter of Colonel Bowness Fischer, late Indian Staff Corps.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

IMPERTINENT ADVERTISEMENT.

WE have received from Messrs. J. Samuda and Co., Limited, a letter, not intended for publication, offering to reply in the following terms to our recent criticisms of their methods: "On the off chance of your being prepared to allow me this privilledge (*sic*), I am writing you to state that I am prepared to write an answer providing you give me a written undertaking to publish the same without alteration or any comment in the issue in which my letter would appear." Messrs. Samuda and Co.'s letter, which, of course, contains the amiable suggestion that if the firm had been an advertiser in our columns no remarks about its methods of doing business would have been published, concludes as follows "One naturally expects criticism if one tries to catch or do the public, but one does not feel it is necessary to protect themselves (*sic*) in carrying on a purely legitimate business." Messrs. Samuda and Co., Limited, are evidently very cross at our expressed opinion that the offer to supply medical men with cigars at a low price so that medical men may recommend these cigars to their patients is impertinent and objectionable. They do not appear to see that the medical profession naturally resents the suggestion that its members should be transformed into touts *for the sale of tobacco. We have no objection whatever to Messrs* Samuda and Co. trying to obtain a market for their wares so long as they do not insult the medical profession in their endeavours, and we have no ill feeling towards the firm as they allege, even though they have brought a vulgar accusation of corruption against us. But the situation is so absolutely clear that we do not think that Messrs Samuda and Co. will be able to alter it by any letter of protest. We cannot, of course, promise to publish their communication until we have seen it and if we do publish it we cannot promise to abstain from correcting any misstatements in it. With regard to publishing "the same without alteration" as Messrs. Samuda and Co. would bind us to do, are they quite prudent in depriving themselves of the assistance of our proof-readers in the matters of grammar and spelling?

A NURSE-INSPECTOR OF SCHOOLS.

To the Editors of THE LANCET.

SIRS,—"L.R.C.S., &c.," sends an instructive letter. Perhaps the following may also be of interest. A school boy was brought to me by his mother with a lacerated wound over the right eyebrow. The wound, which had been dressed by the boy's teacher, was not doing well. My examination revealed (*a*) no attempt to secure apposition of the cut edges, (*b*) a clot interposing which had become septic. The mother, being annoyed at the careless dressing, complained to the head mistress. This lady's comment was that she was sure her teachers could dress an ordinary wound equal to any doctor. It appears that here, in Bethnal Green (with the sanction of the County Council which supplies the dressings), all teachers who hold the St. John Ambulance certificate are allowed to do a medical man's work.

I am, Sirs, yours faithfully,
L.S.A.

"AN AUTHORISED BONESETTER."

THERE is a person named Blackbourn who appears to have selected Lincolnshire as a field for his exploits, who advertises himself by handbill as the "authorised bonesetter" to unions of fishermen, firemen, sailors, dockers, and railway hands, and who publishes a testimonial from the guardians of the Spilsby union. The value of testimonials obtained from sufferers is known to all the world, the patient being, as a rule, violently grateful when the treatment has had nothing to do with the result. But a board of guardians is in a different position and one that ought to enable it to be more critical. Hence we are surprised to find the Spilsby guardians authorising their clerk to write a testimonial for a quack, while we wonder how far those who have thus made themselves responsible for a sort of popular and official approval of the said quack's methods have any first-hand knowledge of the circumstances.

A RECIPIENT OF MANY DEGREES.

WHO is the most favoured recipient of honorary degrees at the hands of various universities? There is no need in replying to this question to speculate upon the amount of complimentary degrees held by, say, Lord Lister or Lord Kelvin. These and all other likely candidates for seniority are, we believe, beaten right out of the field by "John Hopkins." Every time that Professor Osler, for example, the ex professor of medicine in the famous Baltimore University, received a complimentary degree John Hopkins of Baltimore scored equally, becoming (at any rate in British newspapers) a D.Sc., a D.C.L., and a five barrelled LL.D. Now that Professor Halsted, professor of surgery in the same University, is being honoured by the Royal College of Surgeons of Edinburgh, John Hopkins is having an honorary Scottish degree conferred upon him by quite a large section of our press, and we are sure that he has similarly obtained credit for many honours obtained by other professors at the Johns Hopkins University. We think that it is getting time that the existence of the Johns Hopkins University at Baltimore should become more obvious to some of our journalists, for it really is rather a well-known institution.

HEALTHY COSTUME FOR GIRLS.

To the Editors of THE LANCET.

SIRS,—I think that "B A." would find the information he requires in some of the recent numbers of the *Dress Review* and in one or two of the pamphlets published by the Healthy and Artistic Dress Union, which can be obtained from the honorary secretary of the union, Miss Maude A. Biggs, 3, Alexandra road, South Hampstead, N.W., who would, I am sure, be pleased to answer any questions on the subject.

I am, Sirs, yours faithfully,
July 25th, 1905. R.

To the Editors of THE LANCET.

SIRS,—In reply to "B A." as to the healthiest way of clothing his daughter, aged 14 years, I suggest the following as allowing perfect freedom for the limbs with sufficient warmth. A thin all wool garment extending from the neck to just below the knees to be worn next to the skin, this should be very thin with short sleeves during the summer and medium weight and long sleeves during the winter. A "maid's" corset, with shoulder straps made of stout jean and slightly shaped, this buttons down the front, lacing behind, and has no whalebone or steels. Dark-blue drill knickers should be worn which *button to the lower edge of the corset. The last garment is a petticoat* of striped Oxford shirting with calico bodice which in the winter may be made of Scotch wincey and thin flannel respectively. These clothes should be all changed and washed weekly. It may be noticed that there is no weight on the hips or about the waist, everything hanging from the shoulders. Thin cashmere stockings, reaching well above the knee, and thicker ones for the winter, should be kept up by elastic suspenders from the corset. I am, Sirs, yours faithfully,
July 22nd, 1905. K.

A WARNING.

To the Editors of THE LANCET.

SIRS,—May I draw the attention of your readers to a man, aged from 40 to 45 years, about 5 feet 6 inches in height, with close-cut grey hair, clean shaven fat cheeks, and rather watery eyes, dressed in dark grey lounge suit and a black bowler hat? He says he is travelling in dressings, &c., and reports himself as an old medical student of the Owens College and Durham who has been in Australia for many years. He gives the name of Warren and is not safe to leave alone. He called on me four years ago and left with a hypodermic outfit and is now at his old practices again. I am, Sirs, yours faithfully,
Sloane street, S.W., July 21st, 1905 W. W. WOOLLISCROFT

Inkberrow.—Perhaps our correspondent can give us fuller information, we do not know the substance.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Surrey Advertiser, Reading Mercury, Literary Digest, Plymouth Mercury, Freeman's Journal, Hertfordshire Mercury, Windsor and Eton Express, Liverpool Courier, Eastbourne Chronicle, Morning Leader, St. James's Gazette, Manchester Evening News, Newcastle Journal, Bradford Telegraph, Daily News, Liverpool Post and Mercury, Daily Chronicle, Standard, Echo, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. G. W. Atkinson, Lond.; Aston Union, Clerk of; Mr. J. W. Arrowsmith, Bristol; Ashton-under-Lyne District Infirmary, Secretary of.

B.—Sir Lauder Brunton, Lond.; Mr. R. V. Bapat, Kolhapur; Miss M. A. Brooke, Cirencester; Bristol Royal Infirmary, Secretary of; Messrs. C. Buswell and Co., Lond; Mr. E. Stanmore Bishop, Manchester; Mr. A. M. Barford, Lond.; Dr. Duncan Brown, Newport, Monmouthshire; *British Australasian*, Lond., Editor of; Birkenhead Borough Hospital, Secretary of; Dr. E. A. C. Baylor, Ash; Messrs. Burroughs Wellcome and Co., Lond.

C.—Dr. A. Charpentier, Uxbridge; Mr. A. Cregeen, Liverpool; Mr. J. G. Carruthers, Lond.; Dr. Harry Campbell, Lond.; Children's Country Holidays Fund, Lond., Secretary of; Dr. F. Charlesworth, Port Appin.

D.—Dr. D. Douglas-Crawford, Liverpool; Messrs. Defries and Sons, Lond.; Messrs. S. Deacon and Co., Lond.; Department of Agriculture, Ottawa, Veterinary Director General of; Mr. L. S. Dudgeon, Lond.

E.—Messrs. R. Empson and Co., Lond.

F.—Dr. A. Foster, Inkberrow; Messrs. Farebrother, Ellis, and Co., Lond.; Falkenstein Sanatorium, Director of.

G.—Mr. Mark Golensky, Lond.; Messrs. Gordon and Gotch, Lond.; Dr. A. S. Gubb, Aix-les-Bains; Great Eastern Railway Co., Continental Traffic Manager; Dr. A. S. Grünbaum, Leeds; Mr. J. S. Griffiths, Bristol; Mr. H. W. Gadd, Exeter; Dr. G. L. Gulland, Edinburgh.

H.—Dr. W. J. Howarth, Derby; Messrs. Haasenstein and Vogler, Geneva; Dr. R. Hamilton, Douglas, Isle of Man; The Hydro, Clevedon, Secretary of; Dr. Francis Hare, Lond.; Mr. J. Harris, Lond.; Mr. T. D. Harries, Aberystwyth.

I.—International Plasmon, Lond.; International Surgical Society, Lond., Secretary of; Institute of Chemistry of Great Britain and Ireland, Secretary of; *Il Giornale D'Italia*, Rome, Editor of;

J.—Dr. W. Denton Johns, Parkstone; Messrs. D. Hill Jack and Son, Glasgow; Jay, Playgoers' Club, Lond.; Mr. N. Lane Jackson, Lond.; Walter Judd, Ltd., Lond.; Dr. Robert Jones, Claybury.

K.—Messrs. R. A. Knight and Co., Lond.

L.—London (Royal Free Hospital) School of Medicine for [illegible] Lawrence [illegible]rn" Port-[illegible], Lond.; Lancashire County Asylum, Winwick, Clerk of.

M.—Dr. F. H. Martin, Chicago; Dr. J. G. McBride, Edinburgh; Dr. R. Melocchi, Pizzoferrato, Italy; "Mindful," Reigate; Messrs. J. Maclehose and Son, Glasgow; Mr. Sam Manicham, Saidapet, Madras; Manchester Medical Agency, Secretary of; Dr. T. H. Maclie, Whithorn; Mr. E. Merck, Lond.; Dr. D. McIntosh, Clown; Dr. W. G. McDowell, Lond.

N.—Surgeon P. T. Nicholls, R.N., Chatham; Noble's Isle of Man [illegible] of; [illegible] Exhi-[illegible] [illegible]obert Newman, Lond.; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

O.—Mr. A. J. O'Leary, Liverpool.

P.—Mr. Y. J. Pentland, Edinburgh; Messrs. J. and J. Paton, Lond.; Dr. T. G. Parrott, Aylesbury; Mr. F. A. Pond, Liverpool; *Plumber and Decorator*, Editor of.

R.—Messrs. Reynolds and Branson, Leeds; Royal Society of London, Secretary of; Royal Victoria Hospital, Bournemouth, Secretary of; Rebman, Ltd., Lond.; [illegible]ysicians, [illegible] Messrs. [illegible]nburgh; Royal Hospital for Sick Children, Edinburgh, Hon. Secretary of; Miss May Rathbone, Lond.; Mr. E. G. Righton, Evesham.

S.—Dr. J. O. Symes, Clifton; Mr. W. Greenwood Sutcliffe, Margate; Society of Apothecaries of London, Secretary of; Mr. J. O. Skevington, Windsor; Messrs. S. M. Shamsularfeen and Co., Delhi; Seaman's Hospital Society, Lond., Secretary of; Dr. F. W. Staunton, Waterford; Messrs. J. Samuda and Co., Lond.; Scholastic, Clerical, &c., Association, Lond.; St. Pauli Breweries Co., Lond., Secretary of; Dr. C. F. Steele, Matlock; Mr. J. Stewart, Leicester.

T.—Dr. W. Scott Tebb, Lond.; Dr. Fleetwood Taylor, Lond.; Dr. E. H. Taylor, Dublin.

U.—Mr. G. Upton, Chester.

V.—Dr. F. Vaz, Oporto; Miss J. Vallance, Hove.

W.—Mr. P. W. Williams, Clifton; Messrs. H. N. Warren and Co., Liverpool; Dr. A. Whitfield, Lond.; Messrs. Wyleys, Coventry; Mr. W. A. Wharram, Leeds; Messrs. H. Wilson and Son, Lond.; Dr. R. T. Williamson, Manchester; Mr. Charles Walker, Liverpool.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. G. A. Allan, Glasgow; Ayr County Hospital, Secretary of; Mr. E. Arnold, Lond.; A. A.; A. G. J.; A. T. H.; A. E. T.; A. M.

B.—Mr. W. L. Byham, Sunbury; Mr. G. Byres, Lond.; Mr. H. S. D. Browne, Winchester; Dr. W. H. Bishop, Wylam-on-Tyne; Dr. C. A. Ball, Dublin; Mr. H. H. Ballachey, Heckington; Mrs. Ballin, Lond.; Surgeon R. F. Bate, R.N., Devonport; *Bath Journal*, Manager of; Mr. P. B. Ballard, Port Talbot; Bad Schinznach, Switzerland, Director of Baths of; Mr. W. W. Betenson, Hatch End; Messrs. J. H. Booty and Son, Lond.; *Birmingham Daily Post*, Manager of; Mr. W. R. Barlow, Lond.

C.—Mr. A. W. S. Curties, Ashford; Mr. R. A. Caldwell, Bournemouth; Dr. A. W. Crawford, Newcastle, Western Australia; Messrs. Cleaver and Gerahty, Lond.; C. E. S.; C. J. A.; The Coppice, Nottingham; Mr. W. Corkey, Ebbw Vale; Messrs. Callard and Co., Lond.

D.—Messrs. Down Bros., Lond.; Mr. T. Domela, Mürren, Switzerland; Mr. J. Dale, Statham; Derby County Asylum, Mickleover, Clerk of; David Lewis Epileptic Colony, Manchester; Mr. E. Darke, Lond.

E.—Messrs. Elliott, Son, and Boyton, Lond.; E. C. B.; Dr. G. N. Edmondson, Hednesford.

F.—Messrs. Fletcher, Fletcher, and Co., Lond.; Mr. H. J. Fern, Cork; Mr. A. J. Fairlie-Clarke, Elvington; Messrs. J. S. Fry and Sons, Lond.; Dr. D. Fulton, Los Angeles; Messrs. Feuerheerd Bros., Lond.

G.—Mr. H. Gunnell, Peterchurch; Messrs. Gale and Co., Lond.; Miss Griffin, Redhill; Dr. J. G. Gordon-Munn, Norwich; Mr. J. Greenhalgh, Atherton; Messrs. Guyot Guenin, and Son, Lond.; Mrs. Griffin, Richmond; Great Yarmouth Hospital, Secretary of.

H.—Dr. G. D. Hindley, Lond.; Mr. J. J. Harding, Ballincollig; Mr. E. Huxley, Lond.; Messrs. Abel Heywood and Sons, Manchester; Mr. H. T. Hicks, Lond.; Miss Harper, Aberdeen; *Hamilton Advertiser*, Secretary of; Messrs. Hastings Bros., Lond.; Mr. J. Heywood, Manchester; Messrs Hogg and Son, Lond.; Dr. D. C. Holdsworth, Wakefield; Mr. E. Hale, Colchester; H. S.; Mr. A. B. Hood, Aber Bargoed.

J.—Jeyes' Sanitary Compounds Co., Lond., Secretary of; J. H.; J. M. C.; J. L. C.; J. P. B.; J. B.; J. M. G.; J. H. M.; Dr. S. Jex-Blake, Mark Cross.

K.—Mr. A. Kendrick, Taunton; Dr. W. Kingdon, Lond.; Dr. H. Kerr, Stone; King's County Medical Society, Brooklyn, Treasurer of.

L.—Mr. H. K. Lewis, Lond.; Mr. J. M. Luck, Barming; Mr. R. H. Lucas, Bury St. Edmunds; Locum, Chiswick.

M.—Dr. H. Malony, Ballingarry; Mr. W. Morgan, Lond.; Medicus, Lond.; M. D., Warkton; Manchester Royal Infirmary, Secretary of; M. S. M. D.; Messrs. Masters and Sons, Lond.

N.—Dr. E. Norton, Folkestone; Nottingham General Hospital, Secretary of; N. C.

O.—Dr. P. T. O'Sullivan, Cork; Odol Chemical Works, Lond.; Dr. W. M. O'Connor, Aldershot; Mr. J. M. O'Sullivan, Walton-le-Dale.

P.—Miss Potter, Wolverhampton; Mr. G. F. Phillpot, Bourne Castle; Dr. W. Pasteur, Lond.; Mr. H. Pickering, Tamworth; Pharmaceutical Society of Great Britain, Edinburgh, Secretary of; Dr. T. S. Picken, Bellshill.

R.—Messrs. Raimes and Co., York; Dr. J. C. S. Rashleigh, Okehampton; R. W.; R. B.; Mr. R. A. Ross, Liverpool.

S.—Mr. T. G. Scott, Edinburgh; Swansea General Hospital, Secretary of; Dr. H. K. Smyth, Gwelo; Messrs. H. Simpson and Co., Lond.; St. John Ambulance Association, Lond.; South Devon and East Cornwall Hospital, Plymouth, Secretary [illegible] Messrs. [illegible] Salford Royal Hospital, Secretary of; S. N.; *Sheffield Independent Press*, Manager of; Surgeon, Liverpool; Sheffield Royal Hospital, Secretary of.

T.—Mr. J. Thin, Edinburgh; Toilet Novelties Co., Bristol, Manager of; T. G.; Professor J. J. Thomson, Cambridge;

V.—Mr. J. Villiers, Dover.

W.—Rev. A. W. Watson, Churt; Mr. H. M. Wilson, Hawkes Bay, New Zealand; Mr. P. Wood, Crawley; Mr. W. M. Wood, Lond.; Dr. A. W. Wheatly, Lond.; W. H. H.; W. E. S.; W. P. G.; Warneford Asylum, Oxford, Medical Superintendent of; Mr. S. Wand, Leicester; West Bromwich District Hospital, Secretary of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

The Croonian Lectures

ON

THE CHEMICAL CORRELATION OF THE FUNCTIONS OF THE BODY.

Delivered before the Royal College of Physicians of London on June 20th, 22nd, 27th, and 29th, 1905,

BY ERNEST HENRY STARLING, M.D. LOND., F.R.S.,
FELLOW OF THE COLLEGE; JODRELL PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON.

LECTURE I.

Delivered on June 20th.

THE CHEMICAL CONTROL OF THE FUNCTIONS OF THE BODY.

MR. PRESIDENT AND GENTLEMEN,—From the remotest ages the existence of a profession of medicine, the practice of its art and its acceptance as a necessary part of every community have been founded on a tacit assumption that the functions of the body, whether of growth or activity of organs, can be controlled by chemical means; and research by observation of accident or by experiment for such means has resulted in the huge array of drugs which form the pharmacopœias of various civilised countries and the common armamentarium of the medical profession throughout the world. The practice of drugging rests on the supposition that the functions of the body can be influenced in a normal direction by such means. I propose in these lectures to inquire how far such a belief is consonant with our own knowledge of the physiological workings of the body, how far, that is to say, the activities and growth of the different organs of the body are determined and coördinated among each other by chemical substances produced in the body itself but capable of classification with the drugs of the physician. If a mutual control, and therefore coördination, of the different functions of the body be largely determined by the production of definite chemical substances in the body, the discovery of the nature of these substances will enable us to interpose at any desired phase in these functions and so to acquire an absolute control over the workings of the human body. Such a control is the goal of medical science. How far have we progressed towards it? How far are we justified in regarding its attainment as possible?

I hope to be able to vindicate to you the assumption which is at the basis of medical practice and to show that the activities of, at any rate, the large majority of the organs of the body are coördinated among themselves by the production and circulation of chemical substances, so that the results of physiological researches up to the present justify us in the faith that within a reasonable space of time we shall be in the possession of chemical substances which are normal physiological products, and by means of which we shall be in a position to control not only the activities but also the growth of a large number of the organs of the body.

In man and the higher animals the marvellous adaptations effected by means of the central nervous system are so much in evidence that physiologists have been tempted to ascribe every nexus between distant organs to the intervention of the nervous system; the more so because by this means an adaptation to changes, internal or external, can be effected in many cases within a fraction of a second. But in the evolution of life upon this earth this method of adaptation is of comparatively late appearance and is confined almost entirely to one division of living beings—i.e., the animal kingdom. In the lowest organisms, the unicellular, such as the bacteria and protozoa, the only adaptations into the mechanism of which we can gain any clear insight are those to the environment of the organism and in these cases the mechanism is almost entirely a chemical one. The organism approaches its food or flies from harmful media in consequence of chemical stimuli; it prepares its food for digestion or digests it by the formation of chemical substances, toxins or enzymes. In the lowest metazoa, such as the sponges, there is still no trace of any nervous system. The coördination between the different cells of the colony is still determined by purely chemical means. The aggregation of the phagocytic cells round a foreign body is apparently due to the attraction exerted on them by the chemical substances produced in the death of the injured tissues.

With the appearance of a central nervous system or systems in the higher metazoa the quick motor reactions determined by this system form the most obvious vital manifestations of the animal. But the nervous system has been evolved for quick adaptations, not for the abolition of the chemical correlations which existed before a nervous system came into being. A study of the phenomena of even the highest animals shows that the development of the quick nervous adaptations involves no abrogation of the other more primitive class of reactions—i.e., the chemical ones. Where the reaction is one occupying seconds or fractions of a second the nervous system is of necessity employed. Where the reaction may take minutes, hours, or even days for its accomplishment the nexus between the organs implicated may be chemical. Already we are able, in many cases, to prove the existence of such a chemical nexus and to employ it in artificially producing a state of growth or activity which is in normal circumstances merely a phase in a complex series of physiological changes.

The chemical reactions or adaptations of the body, like those which are carried out through the intermediation of the central nervous system, can be divided into two main classes—(1) those which are evoked in consequence of changes impressed upon the organism as a whole from without; and (2) those which, acting entirely within the body, serve to correlate the activities, in the widest sense of the term, of the different parts and organs of the body.

The first class of adaptations includes those reactions of the body to chemical poisons produced by bacteria or higher organisms and represents one of the most important means by which the body maintains itself in the struggle for existence. The complicated phenomena involved in the formation of antitoxins, of cytolysins, of bactericidal substances, and such like means of protection, have been the subject of much study of recent years and their immediate interest to the practical physician renders it unnecessary for me to devote any time to their discussion, especially as the subject is one to which I have not given any personal attention. The investigation of the second class, that of the correlation of the activities of organs, has by reason of its greater obscurity, or of the greater difficulty of its practical application in medicine, fallen largely to the province of the physiologist and I therefore propose to deal almost exclusively with those members of this class of reactions which have so far been definitely ascertained.

Before, however, entering into details of any particular correlation it may be profitable to consider what we may expect to be the nature of the substance which will in any given case act as a chemical nexus between different organs. We are dealing here with a question of general pharmacology. As Ehrlich has pointed out, the chemical substances which act on the body or parts of the body, producing physiological or pharmacological effects, can be divided largely into two main groups. Ehrlich's conception of the first group is bound up with his conception of the nature of the living protoplasmic molecule as a living nucleus with side chains of various descriptions. Assimilation of foodstuffs consists in the linking on of the food molecule as a fresh side chain to the central nucleus. The common feature among the substances of the first class is their close resemblance to an assimilable substance or foodstuff. All these substances acquire a close attachment to, or even identification with, the living protoplasm, and as a rule their effects are apparent only after sufficient time has elapsed for their building up into the protoplasmic molecule. To this class belong the numerous substances closely allied in their chemical character to the proteids which are designated as toxins. All are produced by the agency of living organisms. I need only adduce as examples the various products of the pathogenic bacteria, such as diphtheria and tetanus, the poisonous toxins of higher plants, such as ricin and abrin, and those formed as a weapon of offence by higher animals, such as the active principles of the various snake venoms. According to Ehrlich, these all resemble assimilable foodstuffs in that they possess a haptophore group by which they can anchor themselves on to the living molecule, becoming thus part of its side chains. The toxophore group thus introduced into the living molecule upsets and disorganises its reactions, leading by disorder of one or more functions to the death of

No. 4275.

the animal. In most cases the toxophore group, at any rate, is specific for some definite tissue or type of cell. Thus tetanotoxin exercises its effect almost entirely on the peripheral sensory neurones. It is doubtful, however, whether the haptophore group is so specific, if we are to accept Ehrlich's conception of the mode of formation of antitoxins; since we may get formation of antitoxins in animals where the toxic effect is entirely wanting.

The idea that these toxins ape the part in the protoplasmic molecule of an assimilable foodstuff does not involve as a necessary sequence the formation of antitoxins or antibodies to the normal foodstuffs. That, in fact, the power of assimilation is independent of the power to produce antibodies has been shown by van Dungern in a research specially directed to determine this point. This observer found that the proteids of crabs' blood could be injected into the blood stream of the rabbit and undergo assimilation. Being proteids foreign to rabbits' blood their injection provoked the production in the latter of a precipitin for crabs' blood plasma, but the assimilation of the proteid and the production of the precipitin were found to be absolutely independent phenomena.

The first group therefore of pharmacological substances may be defined as substances presenting many points of resemblance to proteids, potent like enzymes in infinitesimal doses, and giving rise as a result of their introduction into the body to a reaction consisting in the production of an antibody.

Ehrlich's second group of substances, which includes practically all our common drugs, probably act on the protoplasmic molecule or part of it by reason of their chemico-physical properties or their molecular configuration. It is difficult to give a more definite expression of their mode of action. We know that in many cases slight changes in the molecule, such as the introduction or withdrawal of an ethyl, methyl, or NH_2 group into or from a drug or group of drugs, alter their physiological actions in a regular manner. We know, moreover, that substances of the most diverse constitution, such as the various anæsthetics, may have little more than their fat solvent powers in common. All these drugs, however, are more or less stable compounds, generally to be obtained in a crystalline form and not easily destroyed by heat. On introduction into the body the incubation period of their physiological effects is generally determined only by the time necessary for their distribution to, and their diffusion into, the cells which they chiefly affect. Although repeated doses of them can set up a certain degree of tolerance, in no case is there any evidence of the formation of a physiological antidote or antitoxin to the poison.

To which of these two groups of bodies must we assign the chemical messengers which, speeding from cell to cell along the blood stream, may coördinate the activities and growth of different parts of the body? The specific character of the greater part of the toxins which are known to us (I need only instance such toxins as those of tetanus and diphtheria) would suggest that the substances produced for effecting the correlation of organs within the body, through the intermediation of the blood stream, might also belong to this class, since here also specificity of action must be a distinguishing characteristic. These chemical messengers, however, or "hormones" (from ὁρμάω, I excite or arouse), as we might call them, have to be carried from the organ where they are produced to the organ which they affect by means of the blood stream and the continually recurring physiological needs of the organism must determine their repeated production and circulation through the body. If they belong to the first class and are analogous to the toxins, each production of a given substance and its discharge into the blood stream must give rise to the formation of a specific antibody, which must increase in amount with each production of the substance in question and tend therefore to neutralise its physiological effects. It might be suggested that in the case of these chemical messengers the formation of an antibody was a local one and limited to the organ affected and that, in fact, their physiological effect—e.g., secretion—was actually a pouring out of the antibody to the chemical messenger. But, as we shall see later, experimental evidence is entirely against this view, which, moreover, is not supported by any known instance of a similar localisation of antibody as a result of injection into the organism of any of the substances which belong definitely to the toxin class. The formation of antibodies appears, in fact, to be not a process of value in the normal physiological life of the organism but one which has been evolved as a chemical means of defence to prevent the spread of injurious substances from the spot originally affected or attacked.

We are therefore forced to the conclusion that if the processes of coördination of activities among the organs of the body are carried out under physiological conditions to any large extent by chemical means—i.e., by the despatch of chemical messengers along the blood stream—these emissar substances must belong to Ehrlich's second order of substances acting on the body and must, in fact, fall into th same category as the drugs of our Pharmacopœia. Among these, indeed, specificity is not wanting and is the basis o their classification by pharmacologists. Thus we have drug elevating or depressing the activity of the nervous system we can excite secretion in all the glands of the body b pilocarpin; we can stimulate and finally paralyse th præganglionic nerve endings of the sympathetic system by the injection of nicotine, or arouse the anabolic mechanism of the heart by the administration of digitalis. In all these cases we are certainly interfering with normal processes The methods, however, which we employ are not at variance with those made use of by the body itself in securing the harmonious coöperation of its various parts.

In discussing the internal chemical reactions of the body it will be convenient to divide them into two classes—viz., those which involve (1) increased activity of an organ, and (2) increased growth of a tissue or organ. In both cases we must assume that the reaction to the chemical stimulus is itself chemical, the first class including, however, those changes which are chiefly katabolic or dissimilative and are always associated with activity, and the second class involving diminished katabolism and increased building up or anabolism. We might, in fact, speak of the two classes of chemical stimulants as augmentor and inhibitor.

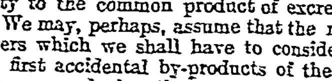
Reactions involving Increased Activity of Organs.

The most striking because the simplest of this class of reactions is that which determines in higher animals the adequate supply of a contracting muscle with oxygen and removal of its chief waste product, carbon dioxide. The increased depth and frequency of respiration contingent on muscular exertion are familiar to everyone and we know that the physiological object of such changes is to secure the increased ventilation rendered necessary by the enormous rise of gaseous metabolism which accompanies muscular exercise. Even moderate work may raise the gaseous exchanges to between four and eight times their amount during rest. This increase in the respiratory movements is entirely involuntary and may, in its earlier stages, when affecting chiefly depth of respiration, be absolutely unnoticed by the subject of them. How is the respiratory centre aroused to an increased activity which is absolutely proportional to the increased metabolism of the distant muscles? A nervous path is at once excluded by the fact that hyperpnœa or even dyspnœa may be excited in an animal after division of the spinal cord by tetanisation of the muscles of the hind limbs and Zuntz and Geppert came to the conclusion that the exciting agent in this increased activity was some acid substance or substances produced by the contracting muscles and transmitted from them through the blood stream to the respiratory centre. The subject has been lately investigated in this country by Haldane and Priestley. In a series of masterly experiments these observers show conclusively that the chemical messenger in this case is none other than carbon dioxide. The contracting muscle, when properly supplied with oxygen, takes up this gas and gives out carbon dioxide in direct proportion to the energy of its contractions. The carbon dioxide diffusing rapidly into the blood stream raises its percentage and, what is still more important, its tension in this fluid. The respiratory centre differs from the other parts of the central nervous system in having developed a specific sensibility to carbon dioxide. Its normal activity is determined by the normal tension of this gas in the blood and lymph bathing the centre. Diminution of the tension of this gas depresses the activity of the centre, causing slackening of respiration or even the total cessation of respiratory movements known as apnœa.

This work by Haldane may be regarded as finally deciding a question which has been the subject of debate for nearly half a century. The dyspnœa caused by the circulation of venous blood through the brain and by the deprival of the respiratory centre of the means of maintaining its normal gaseous interchanges has been variously attributed either to oxygen starvation or to carbon-dioxide intoxication of the centre. Haldane shows that the centre is very little sensitive to changes in the oxygen tension of the blood. The oxygen tension in the pulmonary alveoli may be altered from 20 per cent. to 8 per cent., without any increase in the depth or frequency of the respiratory movements. In these circumstances the heart or circulatory system may feel the deprivation of oxygen before the respiratory centre has responded to it. On the other hand, a rise of only ½ per cent. in the tension of carbon dioxide in the alveolar air and therefore in the blood circulating round the respiratory centre will increase the volume of air respired 100 per cent.

This simplest of all examples of a coördination by chemical means of two widely separate organs may, perhaps, give us a clue to the mode in which the more complex of such correlations have been evolved. In this case the chemical messenger is a product of activity which is common to all protoplasm and must be excreted by the cell as a condition of its further activity. The special adaptation in this case therefore is not the formation of a special substance which shall exert a specific influence on some distant organ but the development in this distant organ of a specific sensibility to the common product of excretion of the first organ. We may, perhaps, assume that the more specialised messengers which we shall have to consider in detail later were at first accidental by-products of the selfish activity of the organ producing them, the first step in the development of a correlation being the acquisition of a sensibility to the substance in question by some distant organ.

The only other example of such a reaction, in which we know both the source and nature of the chemical messenger and the exact nature of the effects which it produces, is the suprarenal gland. Since the time of Addison we have known that atrophy of these glands in man leads to a disease characterised by the three cardinal symptoms of bronzing, vomiting, and extreme muscular weakness. Most of the attempts to reproduce this disease in animals have failed, owing to the fact that death follows the excision of both glands within 24 hours; the extreme muscular weakness is certainly produced, and this is attended by a profound fall in the general blood pressure. In 1894 Oliver and Schäfer showed that from the medulla of the suprarenals a substance could be extracted which, on injection into the circulation, caused marked rise of blood pressure and increased strength of the heart beat. Since the publication of these observations our knowledge on the nature and actions of this substance has progressed rapidly. The researches of Jowett in this country, of Abel in America, and of von Fürth in Germany, have shown that the active substance is a definite chemical compound derived from pyrocatechin and having the formula—



Takamine, by the elaboration of a method for its preparation from the gland in a state of purity, has placed in the hands of the druggist a means of supplying the substance in bulk to the medical profession for therapeutic purposes. The exact knowledge of the constitution of adrenalin thus acquired has paved the way for the actual synthetic formation of this substance. Here, again, there has been a keen international rivalry and the credit of its synthesis must be divided between this country and Germany. It is gratifying that the only original investigation of the subject which has yet been published as a contribution to science is the admirable account by Dakin of his synthesis not only of adrenalin but of a whole array of substances which are closely allied to this body in their chemical structure as well as in their physiological influence on the animal organism.

In order to comprehend the point of attack of adrenalin, the specific secretion of the medullary part of the suprarenal glands, we shall do well to go back to the mode of development of these organs. It was shown by Balfour that the suprarenals have in the fœtus a twofold origin, the cortex being derived from the mesoblastic tissue, known as the intermediate cell-mass, while the medulla is formed by a direct outgrowth from the sympathetic system, and consists at first of an aggregation of neuroblasts. In some animals—e.g., teleostean fishes—the two parts of the gland thus formed remain separate throughout life, but in the higher vertebrates the sympathetic outgrowth becomes surrounded by the cortex and the cells rapidly lose all traces of resemblance to a nerve cell. But the medulla is genetically part of the sympathetic system, and its specific secretion, adrenalin, has an action which is apparently confined to the sympathetic system. In whatever part of the body we test the effects of adrenalin we find that they are identical with the results of stimulating the sympathetic nerve fibres which run to that part. Thus, in all the blood-vessels of the body adrenalin causes constriction; the contraction of the heart muscle is augmented, the pupil is dilated, while the intestinal muscle, with the single exception of the small ring of muscle forming the ileo-colic sphincter, is relaxed. The action of the sympathetic on the bladder differs, as shown by Elliott, markedly in various animals; but, whatever its effect, a similar one will be produced in the same animal by the injection of adrenalin. I have already mentioned that excision of the suprarenal bodies causes a profound fall of blood pressure, which continues until the death of the animal, and it has been stated that when this fall is well established it is impossible to raise the blood pressure by stimulation of the splanchnic nerve or, indeed, to produce any effect at all on stimulation of the sympathetic nerve. Thus not only does adrenalin excite the whole sympathetic system in its ultimate terminations but its presence in the body as a specific secretion of the suprarenal bodies seems to be a necessary condition for the normal functioning, by ordinary reflex means, of the whole sympathetic system. We are dealing here with a problem which, betraying, as it does, an intimate relationship between nerve excitation and excitation by chemical means, promises by its solution to throw a most interesting light on the nature of the nerve process and of excitatory processes in general.

Our knowledge of certain other members of this group of chemical reactions is so shadowy that a mere mention of them will suffice. As an antithesis to the vaso-constrictor action of adrenalin we find that every organ when active is supplied with more blood in consequence of a vaso-dilatation of the vessels which supply it. In certain instances Bayliss and I have found that boiled extracts of organs when injected into the circulation may evoke vaso-dilatation of the same organs of the animal under investigation and we have suggested that the normal vaso-dilatation accompanying activity is brought about in consequence of the specific sensibility of the arterial walls to the metabolites of the organ which they supply. Too much stress, however, cannot be laid upon these experiments since a more extended series by Swale Vincent has failed to give a general confirmation of our results.

The severe diabetes which, as shown by Minkowski, can be produced in nearly all animals by total excision of the pancreas has been held to denote the normal production in this organ of some substance which is indispensable for the utilisation of carbohydrates in the body. All efforts to obtain a more exact idea of the nature of this pancreatic substance or influence have so far proved in vain. Ordinary sugar, when placed in contact with extracts of muscular tissues, undergoes oxidation; and Cohnheim states that this process is much accelerated if an extract of pancreas be added to the extract of muscle. A repetition of Cohnheim's experiments by other observers has shown that the effect is so small as to be almost accidental; and we must therefore regard the nature of the pancreatic influence on carbohydrate metabolism and the causation of pancreatic diabetes as problems still to be solved.

So far (except in the case of the muscle—respiratory centre reaction) we have been dealing with isolated phenomena occurring in different parts of the body in which the reaction affects a whole series of tissues. The chemical stimulus in these cases might be considered analogous to alterations in the composition of the surrounding medium and the reactions lack that definite and localised character which we have learnt to regard as distinguishing the adaptations or reflex actions brought about by the intermediation of the central nervous system. We have now to discuss the mechanism of a whole series of chemical reactions where this feature of a nervous reaction is not wanting, so that, in fact, the reactions, up to quite recently, were regarded as undoubtedly nervous in character. I refer to the chain of processes in the alimentary canal by which the secretion of one juice succeeds that of another as the food progresses along this tube. This series of reactions may well form the subject of a separate lecture.

ON

CARBOHYDRATE METABOLISM.

A Course of Advanced Lectures in Physiology, delivered at the University of London,

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,

HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL; CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

LECTURE III.[1]

GENTLEMEN,—Absorbed from the alimentary canal and utilised in the tissues, how does carbohydrate pass from one locality to the other without giving evidence of its transit through the circulation by the filtering action occurring in the kidney? This is the problem that we have now to consider, and I think it will be found that we need not go further than the seat of absorption to meet with its solution. Let us closely examine the operations that can be shown to be here taking place.

We have seen that the object of digestion in preparing food for absorption is to break down the large molecular constituents of it and thus carry them from the colloidal into the diffusible state. It was formerly considered that this is all that is requisite, absorption being regarded as taking place in compliance with the laws of osmosis. The effect of modern research, however, is to show that it is by the instrumentality of cell action instead of by physical osmosis that the products of digestion pass into the system. Waymouth Reid by means of a number of well-devised and carefully conducted experiments has demonstrated that the integrity of the intestinal epithelium is necessary for the proper procedure of absorption. In the concluding paragraph of a paper on Intestinal Absorption of Solutions[2] he says, with reference to glucose, "it appears from a study of the absorption of weak solutions of glucose that, with the intestinal membrane as normal as the experimental procedure will permit, phenomena present themselves which are as distinctly opposed to a simple physical explanation as are those previously studied in the absorption of serum." Selective action has even been shown to be exerted in the absorption of salines and sodium chloride has been found to be taken up in a manner that can only be accounted for by special cell appropriation.

Absorption by cell action may be said to mean bioplasmic incorporation. The absorbed material passes into, and becomes a component of, the living matter. In other words it is assimilated or made to form a part of bioplasm in process of growth. Now, for bioplasmic growth it is requisite for the molecules which are taken on to be of appropriate configuration to become attached to the large and complex biogenic molecules of which they are to form a part. In the absence of the proper configuration they remain untouched, or otherwise expressed, fail to be assimilated. Thus, in the process of digestion, not only is it necessary that large molecules should be broken down into small ones to give the property of diffusibility for the sake of penetration but also that the molecules produced should be of such construction as to be adapted to unite with those into which they are intended to become incorporated. It is the province of the enzymes supplied by nature to bring about this adaptation and unless it is brought about there can be no combination. Saccharose molecules, for instance, have not the requisite conformation for being taken on by the biogenic molecules of protoplasm and unless there were enzyme action to put them into the state of monosaccharide they would remain untouched and simply be absorbed and pass through the system unchanged.

What I have said about preparation by enzyme action for being taken on by bioplasm applies to each of the food principles—proteid, carbohydrate, and fat. They all undergo breaking down into a molecular form suited to enter into combination with the bioplasm with which at the seat of absorption they are brought into contact. This having been accomplished the process that follows is one that may be designated bioplasmic growth and to this I will now direct attention.

Examination of the small intestine, the chief seat of absorption of the products of digestion, reveals a mucous membrane provided with an immense number of small projecting processes known as the villi. Each villus is provided with an epithelial covering and in the central part lymphoid tissue containing lymphocytes and capillary blood-vessels. The lymphoid tissue, a meshwork of intercommunicating spaces, gives origin to a vessel or vessels constituting an initiatory component of the lacteal system. The superficial epithelial cells and the lymphocytes met with in the lymphoid tissue are the structures which, I think, I shall be able to show play an all-important part in connexion with the absorption of nutrient matter.

The epithelial cells belong to the columnar type. In the fasting state they are seen to be characteristically of this form and to present a granular appearance with a well-defined central nucleus. In the actively absorbing state they may undergo alteration. Many of them may be observed to have lost their columnar form and to have assumed more or less of a spheroidal shape. They at the same time become charged with fat which is visible in very various-sized globules and granules. In this state the cell may present a close resemblance to the secreting cell of the liver which also is concerned with fat production. I entered into this subject in my "Physiology of the Carbohydrates, 1894," under the head of Transformation of Carbohydrate Matter into Fat, p. 245 *et seq.*, and gave photo-engravings to illustrate from the rabbit the fatty condition assumed by the villus cell after the ingestion of starchy food consisting of oats. Many of the cells were literally gorged with fat. At the present moment I will not follow this question further. Let it suffice to say that in connexion with the bearings of fat it is specially the epithelial cells of the villus that are concerned.

We now come to a component of the villus which I look upon as playing a most important rôle in connexion with the train of phenomena associated with the passage of food to service in the economy. I refer to the lymphocytes which are present in the lymphoid tissue belonging to the parenchyma of the villi and likewise in the submucous lymphoid tissue throughout the intestinal tract. They constitute small actively growing and proliferating cells which greatly increase in number during the period of absorption of food. Kölliker[3] as far back as the middle of the last century writing about them said: "While digestion is going on, we frequently find the whole parenchyma of the villi densely filled with nuclei, here and there surrounded by cell membranes [lymphocytes are evidently meant], elements which are, perhaps, never entirely absent in a *villus* but are at other times far fewer." It is only in connexion with the small intestine that this special condition is found. Both in the case of the stomach and large intestine a marked difference exists, no more lymphocytes being visible than may be seen in lymphoid tissue elsewhere.

Recently the lymphocyte question in relation to food has been looked at from another point of view. Many workers have been giving close attention to the corpuscular elements of the blood and a branch of study has been established which has already yielded much valuable knowledge and gives promise in the future of yielding more. When reaching the blood, as may be considered their natural course to do, they fall into the generic group that has long borne the name of leucocytes. In former times but little was known about this group of bodies but latterly by staining and improved manipulative procedure for microscopic examination means of differentiation have been afforded and different kinds of leucocytes are now enumerated. The lymphocyte is easily distinguishable from the other leucocytes and thus it can be made the subject of study in relation to varied bodily conditions. Now, by the counting observations that have been conducted it has been found that the blood undergoes considerable alteration with respect to the number of lymphocytes present as a result of the effect of food.

From the concurrent testimony of many observers it may be looked upon as a settled point that the lymphocytes become greatly increased in number in the blood after the ingestion of food. They show a continuous rise up to about the fourth or fifth hour and then a more or less rapid fall.

Gulland[4] speaks of the total number of lymphocytes per cubic millimetre having been found to have been increased by from 3000 to 11,000. This must mean a large accession of proteid matter to the blood as a result of food absorption. From 3500 to 4000 per cubic millimetre is mentioned as ving constituted the ordinary starting point before food. ariable rates of increase are given by others but the eneral admission is that a very notable increase occurs. he condition, in fact, is of a sufficiently established nature o have received the designation of digestion lymphocytosis. his flow of lymphocytes into the blood naturally means, as have already said, a great accession to it of proteid matter. ohl[5] has given the calculation, which I may mention without expressing any opinion as to the value one way or the ther to be attached to it, that 15 grammes represent the mount of proteid that may thus reach the blood after a meal.

Lymphocytes consist of proteid and proteid contains locked-up carbohydrate. In this way lymphocytes become mixed up with carbohydrate metabolism. There is no doubt about the lymphocytes reaching the blood as a sequence to the absorption of food. Examination of the blood obtained by a needle prick through the skin suffices to demonstrate the connexion. Prevailing ideas however, regarding the mode of transit stand in a very tangled state. Looking at the perfection of the arrangement which nature has provided for the purpose it is strange that this should be so. Until some 30 years ago the lacteal system was regarded as constituting the channel for the transport of the absorbed nutrient matter from the alimentary canal into the blood, just as the general absorbent system was looked upon as conveying the unutilised portion of the pabulum that ad escaped from the blood-vessels into the lymph spaces for he nourishment of the tissues. The confusion, I think, lates from Schmidt-Mülheim's work[6] in which the thoracic uct was ligatured and the urinary nitrogen elimination after nitrogenous food estimated and compared with that found in instances where the duct was free. According to the results given no essential difference was discernible. It would be out of place here to discuss this matter but I have looked into it and do not see that it by any means conclusively establishes the deduction that has been drawn and that has driven physiologists in seeking for something else to take refuge in what I feel may be spoken of as the impossible.

As a substitute for the view allocating the passage of the lymphocytes to the lacteal tract it has been suggested—and the idea carries credence at the present time—that they reach the circulation by traversing the walls of the capillary vessels. Even in the most recent work we find observers looking in the mesenteric veins for the lymphocytes produced in the villi. Could there be any conception more opposed to physical laws? Picture a lymphocyte, constituted as it is, passing from a lymphoid lacuna through the walls of a capillary against the pressure existing within. It is intelligible for leucocytes to pass through, as is known they do, in the opposite direction under the influence of the capillary blood pressure existing, just as mercury may be forced through the pores of chamois leather, but to traverse a membrane with pressure in operation against them seems o me to be nothing short of an impossibility. Presumably, it may be further said that even with proteid molecules the same governing factors bring about a corresponding result. Because under the capillary pressure, and apparently in proportion to it, proteid passes from the vessels into the lymph which bathes the tissue elements, it does not follow that it should be possible for the reverse to occur, or, in other words, for the proteid that has escaped nutritive appropriation in the lymph spaces, wherein there exists a lower pressure than in the capillaries, to pass back in a direct manner into the blood.

It is not disputed that lymph corpuscles are to be found in the contents of the lacteal vessels but it is considered that they have not been found in sufficient quantity to account satisfactorily for the digestion lymphocytes that reach the blood. There is a point in connexion with looking for them that appears to me not to have received proper attention, at all events I have never seen it alluded to. In the process of coagulation the lymphocytes become entangled in the coagulum in the same manner as occurs with the corpuscles of the blood, and the place to look for them is hence in the coagulum and not in the fluid. I am in the habit of preventing coagulation by the employment of a little citrate of potash and thus the examination is rendered much easier. The fact of lymphocytes being discoverable within the lacteal system affords proof that transport through this channel occurs. I can state from my own observation that they are to be found throughout the different parts of the lacteal system. It is not difficult to obtain chyle for microscopic examination that is on its way to the mesenteric glands and I can distinctly assert that lymphocytes are recognisable in it. They appear to be more numerous after the glands have been traversed. If lymphocytes are to be found passing along nature's channel it shows that this track is in actual use for the purpose, and hence it follows that any other mode of transit would be simply supplementary instead of one of absolute necessity. Now, seeing that the imaginary supplementary transit stands totally in antagonism with physical laws, can it for a moment be allowed to retain the position it at present holds? The granules constituting the molecular base of chyle and likewise fat globules pass. Of this there can be no possible doubt. Why, then, should there be any question existing with regard to the lymphocytes? The channel is more than sufficiently capacious to meet what is wanted for their passage and if some passed why should not all do so?

The flow through the lacteals is greatly increased at the digestion period. Although the contrary may have been asserted, yet in reality the matter does not admit of dispute. At a period of full fasting the vessels are not to be seen and are probably in a more or less completely empty state with attendant stasis. During active digestion and absorption, on the other hand, they stand out conspicuously and when incised give immediate exit to an abundant flow of chyle. In harmony with this state the villi are more prominent and loaded with lymph corpuscles. Notwithstanding former denials it may be considered that present-day work is in accord with this assertion.

The villi, then, may be regarded as a propagating and rearing ground for the lymph corpuscles I have been considering. They grow, I would say, upon the nutrient matter derived from the digested food like yeast cells grow in a suitable pabulum or bacilli in a culture medium. Developing in this way and travelling along the lacteal tract they become carriers of assimilated food principles into the system and reaching the circulation pass under the denomination of digestion lymphocytes. I will not at the present moment enter into the question of what subsequently becomes of these corpuscles. As yet I have only dealt with them morphologically, but I have to speak of the chemical bearings belonging to them and it will be convenient to reserve what I have to say about their destination until after these have been considered.

Lymphocytes consist virtually of little masses of bioplasm and the property of bioplasm is to assimilate or to incorporate within itself matter which is suited for the purpose. They may be compared to unicellular organisms and may be said to grow independently upon the nutrient matter around them. In this growth the molecules of the nutrient matter become linked on to the proteid molecules of the augmenting bioplasm in a manner to lead to the extension that ensues. For this a reciprocal relation must exist between that which is taking on and that which is taken on, and it is by enzyme action that provision is made for bringing about the required relationship condition. This having been effected the union takes place by virtue of affinity—a power by which atoms and molecules are drawn into chemical combination and therefore a power of supreme importance in the domain of chemistry.

We know how some atoms and molecules when brought together enter into chemical union whilst others show no disposition to do so. We know also where affinity exists that it does so under very varying degrees of strength. The effect of affinity is conspicuously realisable in the inorganic kingdom. It is not so self-evident in connexion with the organic kingdom but nevertheless I take it that it stands at the foundation of the combinations that occur. The expansive power of a growing structure may be very great, as is made manifest by the damage of building constructions sometimes perceived to be occasioned by the growth of trunks and roots of trees. I remember upon one occasion having seen a heavy paving stone raised out of place by a ramified fungus growth underneath. Instances of this kind bring home to us the fact that in the molecular combination associated with growth there must be no mean amount of attraction force at work.

In the lymphocyte bioplasm then there exists the aptitude for taking on the food molecules to which the requisite configuration has been given by enzyme action. Peptone is representative of the nitrogenous portion of the food and glucose of the carbohydrate. They both are found on absorption to disappear. Hofmeister,[7] commenting on the disappearance of peptone, suggested that it was taken hold of by the lymphocytes and that bound up in these it could traverse the circulatory system without filtering off when passing through the kidneys. Pohl[8] speaks of the proteid of the food being first broken down by digestion and then built up again by the lymphocytes into the proteid specifically belonging to the animal in which the action occurs. The lymphocyte, he adds, must subsequently become dissolved in blood plasma or be taken by the tissues. A. Mathews, in an article on the Origin of Fibrinogen,[9] enters into the question of the transformation of food proteids into blood proteids, refers to Schmidt's and Mörner's observations pointing to paraglobulin being derived from disintegrating leucocytes, and himself adduces evidence suggestive of leucocytes being the source of fibrinogen.

All this touches upon the point that is before us, which is the function of the lymphocyte in assimilating digested foodstuff and what subsequently becomes of the assimilated material. It will be noted that in the views of the various authorities which have been mentioned reference is only made to the peptone product of digestion. I have to suggest that the action should be extended and made to embrace carbohydrate—that carbohydrate and peptone stand upon the same footing as regards the manner in which they are dealt with by the growing bioplasm of the intestinal lymphocytes, that both become linked on to the biogenic molecules of the lymphocyte and thus made to enter into the constitution of living matter in which the various chemical changes of metabolism are wrought out. Hofmeister's remark about peptone being placed by the assimilative action of the lymphocytes into a position to traverse the circulation without filtering off with the urine applies with equal force to sugar, of which it may without hesitation be said that if it is to be available for service in the economy it must not be permitted to enter the circulation in the small molecular form represented by sugar.

Under the view set forth the food principles are in the first instance constructed by assimilative action into the principles of the blood. The step that follows is that the tissues derive their nourishment from the elaborated principles of the blood. The blood feeds upon the food supplied from without and the tissues feed upon the blood. I do not see that we can deny to the blood with the standard composition it possesses an inherent assimilative power comparable to that possessed by the tissues. I take exception to the view expressed in a recent communication to the Pathological Society by Dr. W. D. Halliburton.[10] Reference is made in it to the success that has attended Emil Fischer's efforts to synthesise some of the lower cleavage products of proteolysis and it is suggested that a more complete breaking down of proteid occurs in the alimentary canal than has been hitherto supposed, erepsin being specified as the enzyme which has the power of carrying peptones into more rudimentary cleavage products. The new theory is stated to assume a complete breaking down of the foodstuffs previously to their being built up into the living tissue. What, it may be asked, would be the condition of the blood if such a view held good? Instead of a component of the system with as much of a standard constitution as muscle and other structures it would consist of an agglomeration of small molecules in transport to the tissues and in a position to filter off with the urine in passing through the kidney. What also would be the use of the elaborated proteids of the blood if the broken-up foodstuffs were directly conveyed to the tissues and there synthesised? As far as I can see everything stands against the correctness of such a view and what may be said clearly to be wanted is that the synthesis should take place preparatory to entry into the blood.

Because the chemist can as yet only synthesise the more rudimentary molecules into higher combinations it is not to be argued that nature is in the same position. We lack the power of forging the implements by which nature's work is performed. When we get hold of, and apply, these implements—as, for instance, when we operate with enzymes—we can achieve in our laboratory experiments the same that is effected inside the living organism. There are grounds for believing that chemistry works upon the same basis in the organic and the inorganic kingdoms of nature. Affinity and adaptability in molecular configuration are at the root of chemical union and the difficulty in bringing about a desired chemical union in manipulating with the complex organic molecules is intelligible when we look at the intricacy of the conditions that require to be met with respect to molecular configuration. Fischer's simile of lock-and-key arrangement in the fitting together of molecules brings home to us the severity of the conditions that must exist where highly complex molecules are dealt with. The slightest deviation in any particular from the required construction would suffice to throw out the adaptability for union. If the adaptability between the complex peptone molecule and the taking-on molecule of the lymphocyte bioplasm exists, as I consider there are grounds for believing it does, there would be no reason for the proteolysis of digestion to be carried further.

Let me show how the line of argument that has been set forth harmonises with what is taught in connexion with the chemistry of the doctrine of immunity. For this I will quote from Ehrlich's Croonian lecture, published in the Proceedings of the Royal Society for 1900, and will premise by stating that foodstuff and toxin molecules are looked upon as standing in an allied position in relation to the assimilating protoplasmic molecules. At p. 433 Ehrlich says: "We may regard the cell quite apart from its familiar morphological aspects and contemplate its constitution from the purely *chemical* standpoint. We are obliged to adopt the view that the protoplasm is equipped with certain atomic groups, whose function especially consists in fixing to themselves certain foodstuffs of importance to the cell life. Adopting the nomenclature of organic chemistry, these groups may be designated side chains. We may assume that the protoplasm consists of a special executive centre (Leistungs-centrum) in connexion with which are nutritive side chains which possess a certain degree of independence and which may differ from one another according to the requirements of the different cells. And as these side chains have the office of attaching to themselves certain foodstuffs we must also assume an atom-grouping in these foodstuffs themselves, every group uniting with a corresponding combining group of a side chain. The relationship of the corresponding groups, i.e., those of the foodstuff and those of the cell, must be specific. They must be adapted to one another as, e.g., male and female screw (Pasteur) or as lock and key (E. Fischer). From this point of view we must contemplate the relation of the toxin to the cell."

I have spoken of the digestion lymphocytes as little collections of bioplasm growing upon the prepared nutrient principles of the food. I consider that in the exercise of their assimilative or taking on office they deal alike with the products derived from proteid and from carbohydrate matter, and therefore what is said about the action occurring in the one case is applicable to the other. Do not the leucocytes belonging to the blood stand in a similar position in relation to assimilative action? The phagocytes have acquired a renowned reputation through their power of devouring bacilli and other foreign particles and subsequently disposing of them in the same way that the amœba engulfs its food and then digests and makes use of it. This means that assimilation is brought into play and if assimilation is thus put into operation it is only reasonable to infer that it can be applied to surrounding molecules of any description that possess the requisite conformation for being assimilated. Upon such ground the leucocytes may be regarded as constituting the assimilative agency or the living element of the blood, giving to it the general power that is possessed by living matter elsewhere. Thus products which may incidentally reach the blood, either from ingestion or from the tissues, that are susceptible of utilisation may become assimilated and placed in a position to be subsequently made use of. The lymphocytes of the lymphoid tissue, I take it, may be regarded as performing the same kind of duty by assimilating the utilisable products of retrograde tissue metamorphosis and rendering them fit for further use.

We now come to a point which, although an important one, seems to have received but scant consideration by physiologists. In what way do the fibrinogen, globulin, and albumin of the blood take origin? They are highly complex proteids and can only be conceived to arise through the instrumentality of bioplasm. Applying the mind to the matter the following train of reasoning suggested itself to me. I took it for granted that they may be considered as having a close connexion with the food and that there must be some intermediate living agency in operation to produce them. Seeing that lymphocytes constitute a living growth constructed out of the elements of the food, that there is an active flow of them into the circulation connected with food ingestion, and that there is afterwards a melting away of them to be observed, it seemed that in these circumstances a groundwork was presented suggestively affording a solution of the problem before us. May we not look to the gland cell to help us analogically in the matter? The gland cell consists of bioplasm which, in this instance, has grown upon nutrient matter derived from the blood. As part of its life it undergoes autolysis and gives its formed material to its associated secretion. Lysins now constitute a well-known class of implement constructed by nature for the execution of her work and it may be taken that a special lysin is provided for each of the different operations to be carried out. By autolysis of the lymphocytes the material built up by them from the elements of the food would be given to the blood and may not the autolysis occur in such a manner as to lead to the evolution of the proteids of the blood, which in their pabulum character stand in an intermediate position between the food and the tissues? That tissue is in reality built up and maintained by proteids such as those in the blood is shown by the fact that in the egg they unmistakeably constitute the medium from which the tissues of the developing chick derive their nutrient matter. Food into lymphocytes, lymphocytes into proteids, proteids into tissue substance, may be taken as representing the chain of physiological connexion between the food and the tissues.

[10] THE LANCET, March 18th, 1905, p. 717.

In support of the view that has been expressed I have found on looking through the literature of the subject since the idea was framed that A. Mathews,[11] to whose work I have already referred, has adduced experimental evidence in favour of leucocytes constituting the source of fibrinogen and in his paper he alludes to the work of Alexander Schmidt[12] pointing to the likelihood of the paraglobulin of the blood being derived from leucocytes and likewise to that of Lilienfeld and Miescher[13] suggesting the same source for the serum albumin.

The point that has been discussed has a bearing on the application of proteid to energy production. It has long been known that the elimination of urea stands in relation to the proteid food ingested and it is considered that the proteid molecule splits up into a non-utilisable nitrogenous portion which is discharged as urea and a complementary tilisable residue which, whether assuming the form as has een suggested of carbohydrate or not, may be reckoned to ontribute to energy production. It has been difficult to onceive that this combustion proteid passed into the tissues or the purpose of being broken down. Looking upon the rocess as occurring within the lymphocyte there is nothing hat appears incongruous and it is noticeable that the ncreased urea elimination about harmonises with the period f maximum lymphocyte autolysis.

As yet I have only spoken of the assimilation of carbohydrate by being built up into proteid through the agency of bioplasm. Probably when there is no particularly large upply of carbohydrate this is the main result that occurs. When, however, the supply is extensive it is evident that some escapes being disposed of at the seat of absorption and thence reaches the portal blood. At a period of fasting and likewise after the ingestion of animal food the portal blood, as regards the amount of sugar present, corresponds with that belonging to the other parts of the circulatory system. After a free supply of starchy food, however, sugar may be found to be present in the portal blood to a considerably larger extent than anywhere else. In my "Physiology of the Carbohydrates" I entered somewhat fully into this matter and gave a number of experimental results obtained under different conditions with regard to food. The presence of about 2 per 1000 or a little over was of not uncommon occurrence. In two instances figures amounting to 4 per 1000 were met with.

The sugar which escapes assimilation at the seat of absorption and reaches the portal blood is conveyed to the liver wherein it is brought into close relation with the cells of the organ. By these it becomes absorbed and transmuted into glycogen. There is overwhelming evidence to show that this action occurs and if it is complete, as it ought to be, sugar from the food is prevented from reaching the general circulation. It will be seen from the arrangement existing that there is a double provision against the entry of sugar from the food into the general circulation. Whatever may pass the first line of obstruction has to confront the arresting action of the liver. In this way security is provided against the systemic blood receiving an influx of sugar at every meal into which carbohydrate enters.

I look upon glycogen as simply a cleaved-off storage material standing in identically the same position as fat. I think it may be said that we may rightly consider that the sugar is taken on by the bioplasm of the cells and by it transmuted into, and thrown off as, glycogen. This kind of operation is one of the commonest of the operations occurring in connexion with living matter. Starch, cellulose, and a multiplicity of other products are cleaved off from a pre-existing biogenic complex into which something other than the cleaved-off principle has passed in. Ordinary enzyme action is attended with taking on in one form and throwing off in another. Looked at in this way there is nothing mysterious or incomprehensible about the position that glycogen holds and its position in the liver is not different from that which it holds in the numerous other localities in which it is met with. Its presence only means disjoined carbohydrate collected as redundant material in the locality where it is found. The supply of carbohydrate is in excess of utilisation and the surplus is thrown off as glycogen for temporary storage. Yeast cells contain glycogen and it has been noticed that when growing in a 1 per cent. solution of glucose there is only a small amount to be found present, whilst when growing in a 10 or 20 per cent. solution there is much. In the case of the liver it is common knowledge that its glycogen varies with the amount of carbohydrate food-supply. Diminishing the consumption going on by reducing the activity of a part promotes accumulation and conversely increasing the activity leads to diminution. For instance, division of the nerve or tendon of a muscle is followed by an accumulation of glycogen and tetanising the muscle by a diminution.

By severe forced exercise it is found that glycogen may be made to disappear, alike from the liver and muscles, in the course of a few hours without any show of the production of sugar. The seat of actual consumption is in the muscles and therefore in the case of its disappearance from the liver there must be transport in some way or other through the circulatory system. To this point I will give attention.

The outcome of all modern work is pointing in a very strong manner to the taking on and throwing off capacity of organic matter constituting an exceedingly widespread principle of action. I have purposely said organic and not bioplasmic matter, for in the action of enzymes, which can hardly be considered as representatives of bioplasm, have we not a taking on in one form and throwing off in another action to deal with? It is, indeed, difficult to see how the action of an enzyme differs from that which is ordinarily looked upon as constituting a special attribute of living matter. I may even go a step further and say it is difficult to see how the illustrations, which at the present moment are being brought forward by chemists under the head of inorganic ferment action, differ in nature from the occurrences associated with ordinary organic ferment action. Applying the principle of action to which I have been alluding to the point under consideration the suggestion presents itself that sugar is taken on as a side chain by a proteid constituent of the blood and transported to the tissues where it is taken off for subjection to utilisation. The suggested operation is identical with what occurs in connexion with the transport of oxygen. Oxygen is taken on by hæmoglobin and in a state of combination transported to the tissues where it is taken off and applied to utilisation. Glycogen is a storage material consisting of very large molecules and therefore not adapted for shifting its position. I should think that the first action that occurs is the breaking down of its molecule into molecules of glucose which become instantly taken on by the alluded to molecules of the blood. There may be concerted action between the breaking down and taking on processes and this is rendered probable by the fact that there is no show of sugar in connexion with the occurrence. Enzyme action, it may be considered, of necessity constitutes a part of the process and the enzyme concerned and set into motion as needed may in the presence of altered conditions be intelligibly conceived to be capable of producing the deviation from the natural living state that so quickly takes place as a post-mortem occurrence in the liver.

The phenomena connected with phloridzin glycosuria afford confirmatory evidence in relation to the view that has just been expressed. Volume XXIX., 1903, of the *Journal of Physiology* contains a communication by Pavy, Brodie, and Siau on the Mechanism of Phloridzin Glycosuria in which the point in question is dealt with. The conclusion we arrived at from the experimental work performed was that the sugar eliminated is derived from the katabolic action of the renal cells on a constituent of the blood containing sugar in a locked-up state. This idea was previously mentioned at a meeting of the Pathological Society in April, 1902. Loewi[14] has expressed a similar idea and has even gone the length of suggesting that the sugar which is ordinarily looked upon as being in a free form in the blood is in reality in a loosely combined state when the blood is circulating in the body. We did not commit ourselves to agreeing with this proposition, although otherwise we stood in accord with him. It is clearly established that the glycosuria produced by phloridzin is not due to hyperglycæmia and it hence follows that there must be something in the blood to yield the sugar. The first effect of the phloridzin is to sweep away the glycogen that is present in the body. If this passed through the circulatory system as free sugar there ought to be hyperglycæmia in proportion to the glycosuria, which there certainly is not. This being the case, the only conclusion that can be drawn is that the katabolised glycogen (sugar) enters into side chain or loose combination with a constituent (proteid) of the blood and is thus conveyed to the kidney where it is set free and eliminated.

For a great number of years cases of diabetes have from time to time been noticed to have been associated with disease of the pancreas and the feeling has been entertained that a connexion existed between the two. Experimental physiology has since stepped in and shown indubitably that diabetes is producible by extirpation of the pancreas, and the view has been formulated that normally the organ supplies an internal secretion which contributes to the proper disposal of carbohydrate matter in the system. To the islands of Langerhans has been assigned this function and weighty evidence has been adduced in support of the correctness of the view that has been taken. Lépine a long while ago contended that a glycolytic ferment was derived from the pancreas which was instrumental in effecting the destruction of the sugar assumed under the glycogenic doctrine to be constantly reaching the blood, and that the absence of the ferment was the source of diabetes. His view has not received acceptance and I do not consider that I need further allude to it. More recently Otto Cohnheim has conjectured that the pancreas supplies an activator to the ferment which, he says, exists in the muscles for the oxidation of sugar. In view of the anticipated therapeutic value of his pancreatic product in connexion with diabetes it has been made a patented article. Much adverse criticism of his work, however, has been called forth and I myself feel that the matter stands upon a wrong basis. With the assistance of Mr. Bywaters I have entered experimentally into the subject and the evidence that has been obtained has not been of a confirmatory nature.

The work that has been conducted by others has been directed to the side of the destruction of sugar. No one has viewed the subject from the side of the assimilation of sugar, but it seems to me that this is the aspect from which it should be looked at. Enzyme action is concerned in building up as well as in breaking down and an activator is wanted for enabling the bioplasm of the intestinal tract to perform its work in connexion with the assimilation of the absorbed sugar. Let me proceed to explain the matter from the standpoint that I view it.

It has been recently ascertained that enzymes are dual bodies. One portion is insoluble in alcohol, non-diffusible, and destructible by heat. This probably is of a proteid nature. The other—the co-ferment or activator—is usually soluble in alcohol, diffusible, and can be boiled without losing its activity. It corresponds with the active agents that are obtained from the thyroid, suprarenal capsule, &c. A great advance was made when Buchner discovered that the expressed juice of yeast contained the ferment zymase which converts sugar into alcohol and carbonic acid. Harden and Young,[15] in experimenting with zymase at the Lister Institute, have found that a given quantity of fresh yeast juice has its ferment power doubled by the addition of an equal volume of boiled juice. This means that an extra quantity of the activator, which is powerless by itself, gives increased power to the ferment principle in the juice. In a further experiment the yeast juice was subjected to filtration through a Martin's gelatin filter. Neither the filtrate nor the residue on the filter dissolved in water was capable of inducing fermentation, but when they were mixed together they produced fermentation almost equal in extent to that produced by the original juice.

Let it be supposed that the activator supplied by the pancreas is wanted to enable bioplasm to take on or to assimilate sugar. It may be assumed that there is always a certain amount of it in normal circumstances distributed through the system and ready for use. I have long known that the introduction of sugar into the circulatory system was followed by the presence of an increased amount of amylose carbohydrate in the blood, and commented upon the point in my "Physiology of the Carbohydrates." With the information that is now before us the idea is suggested that a portion of the introduced sugar is appropriated by the bioplasm of the leucocytes and converted into proteid carbohydrate. I will draw attention to a tabular arrangement of results showing the amount of amylose carbohydrate found in the blood of rabbits taken ordinarily and in that of rabbits subjected to experimental injection:—

Amylose Carbohydrate from Rabbit's Blood expressed as Glucose in parts per 1000.

Normal blood.	Time between injection and killing.	After intravenous injection of—			
		Saline solution.	1 gramme per kilogramme of—		
			Dextrose.	Lævulose.	Galactose.
1·39	15 minutes ...	1·35 ...	1·60 ...	2·67 ...	1·74
1·34	— ...	1·35 ...	1·53 ...	— ...	1·93
1·39	— ...	— ...	1·52 ...	— ...	—
1·52	— ...	— ...	1·80 ...	— ...	—
1·39	— ...	— ...	— ...	— ...	—
1·40	30 minutes ...	— ...	1·62 ...	2·60 ...	—
1·46	— ...	— ...	— ...	— ...	—
1·25	60 minutes ...	— ...	1·34 ...	1·81 ...	—
1·55	— ...	— ...	1·43 ...	— ...	—
1·44	— ...	— ...	— ...	— ...	—
1·41	— ...	— ...	— ...	— ..	—

It will be seen that in no case did the amylose carbohydrate exceed 1·55 per 1000 in the normal blood whilst in some of the instances after the injection of the sugars the figures stand considerably higher. Dilution of the blood would be occasioned by the injection and the effect of this with the animal killed shortly afterwards would be to reduce the proportionate amount of amylose carbohydrate. The condition found to exist at the end of 60 minutes is interesting. It shows that with the advance of time there is a tendency for the effect of the injection to work off.

In another set of experiments pancreatic extract was

injected in association with the sugar. The extract was prepared by mixing the pancreas, which had been pounded with sand, with water, boiling, and filtering. The amount of extract used was such as to give a relation of about one gramme of pancreas per kilogramme of body-weight. The results have been arranged in a tabular form. After raw extract of pancreas and one gramme per kilogramme of dextrose, which immediately caused death, the figures given were 1·04 per 1000.

Other experiments were conducted in which the sugar and extract were injected subcutaneously instead of intravenously. The results have also been arranged in a tabular form.

Amylose Carbohydrate from Rabbit's Blood expressed as Glucose in Parts per 1000.

Time between injection and killing.	After subcutaneous injection of pancreatic extract and 1 gramme per kilogramme of—		
	Dextrose.	Lævulose.	Honey sugar.

—	1·52	—	—
2 hours	1·77	—	1·49
—	1·23	—	1·74

Taken altogether a long list of experimental results is presented for grounding a judgment upon. The same method of procedure was adopted in all the experiments. Unmistakeably different figures are seen to have been obtained after the injection of pancreatic extract and sugar from those yielded in the other experiments. The effect of the employment of the pancreatic extract is suggestive of its holding a corresponding position to the activator in the yeast juice experiments that have been referred to. It will be noticed that in one of the experiments raw pancreatic extract was employed and that immediate death followed. In this experiment there was no elevation of the figures.

I have only dealt with one of the methods of disposal of carbohydrate in the animal system. There is another and it evidently must be regarded as holding a highly important position. I refer to the transformation of carbohydrate into fat, a process upon which an extensive industry is founded, seeing that it is at the basis of the fattening of animals with carbohydrate food. I gave consideration to this process in my "Physiology of the Carbohydrates" and showed that the superficial epithelial cells of the villi and the liver cells may be regarded as constituting the operative agents. To the lymphoid cells then of the villi I assign the office of metabolising carbohydrate into proteid and to the epithelial cells that of metabolising it into fat.

A few words in conclusion regarding diabetes. Viewed from the standpoint that I have taken it is the result of a wrong carbohydrate metabolism on the side of assimilation and in some cases on that of breaking down as well. In the "alimentary" form of the disease the carbohydrate fails to be properly assimilated and prevented from reaching the circulatory system in the small molecular state of sugar. In the "composite" form there is defective assimilation and at the same time a faulty tissue breaking down. The carbohydrate, which has been locked up in combination, instead of passing on to proper oxidation becomes liberated as free sugar and thence escapes from the system as waste material. As long as carbohydrate is properly assimilated and sugar is thus prevented from reaching the general circulation there can be no sugar passing into the urine from the food. Let the assimilative process fail and immediately sugar finds its way into the circulation and thence into the urine, just as if it had been directly introduced by an intravenous injection.

THE SPA TREATMENT OF CIRCULATORY DISORDERS.*

BY LEONARD WILLIAMS, M.D. GLASG., M.R.C.P. LOND.,
PHYSICIAN TO THE FRENCH HOSPITAL, LONDON.

SINCE the introduction of what is known as the Nauheim system into this country and the rather comprehensive claims originally put forward on its behalf the spa treatment of circulatory disorders has been in danger of becoming synonymous with effervescent baths and resistance exercises. As the application of this system is in reality very limited, and as its popularity threatens not only to damage the system itself but also to obscure the real advantages to be obtained from properly directed health resort treatment, the time seems favourable for a brief review of the whole question.

With regard to the Nauheim treatment itself, it is perhaps unnecessary to insist that it can be obtained elsewhere than at Nauheim. At Buxton, Bath, Harrogate, Sidmouth, Leamington, and Llangammarch, to mention but a few of our own health resorts, the baths and exercises can be carried out with intelligence and circumspection by physicians experienced in the treatment; and in London, as well as in a great many of the large provincial centres, the system can be applied at institutions and nursing homes by efficiently trained attendants. To reach Nauheim it is necessary to undertake a journey of nearly 24 hours' duration and even when this has been successfully accomplished the conditions in which the patient finds himself are by no means ideal. The town, it is true, is well drained, the water-supply is good, and the accommodation excellent, but the climate is unsatisfactory. Lying as it does at the foot of the Johannisberg and fully exposed to the east its rainfall is heavy and it is liable to sudden and decided changes of temperature. It is a summer resort, the season lasting from May till September, but the east winds which often prevail in May render that month unsuitable; the rains in September are generally severe, and the heat during July and August is not infrequently unbearable. From the points of view of climate and accessibility therefore Nauheim is by no means a place to which a cardiac patient should lightly be advised and he who neglects these elements in the selection of his spas does much to jeopardise his credit.

Of the treatment which has made the place famous it may be said at once that useful as it undoubtedly is in suitable cases the number of those cases is not large. As everyone now knows this treatment consists in the administration of cold or tepid saline baths which evolve a considerable quantity of carbonic acid gas, combined, usually, with resistance exercises and, occasionally, with graduated hill-climbing on the principle known as the Terrain-Kur of Oertel. So far as the last two items are concerned, and they are, from the researches of Oliver, Leonard Hill, Lauder Brunton and Tunnicliffe, probably by far the most important factors in producing the results, they are neither peculiar to, nor did they originate at, Nauheim. As long ago as 1854 Dr. Stokes of Dublin[1] wrote as follows: "The symptoms of debility of the heart are often removable by a regulated course of gymnastics or by pedestrian exercise, even in mountainous countries such as Switzerland or the Highlands of Scotland or Ireland....... During the first period of the day the patient suffers from dyspnœa and palpitation in an extreme degree, but by persevering without over-exertion or after a short rest he can finish his day's work and even ascend mountains with facility." 30 years later Oertel[2] of Munich developed the idea thus expressed and it was put into practical application at several health resorts, notably at Reichenhall and Ischl. Exercises and gymnastics were also used by Saeterburg of Stockholm and Zander as early as 1862 with excellent results.

In considering the system there remain then to the credit of Nauheim's initiative in cardio-therapeutics the saline effervescing baths about which so much has recently been heard. We are fortunately beyond the time when the remedial effects of waters applied externally can seriously claim to be due to some occult subterranean chemical combination. In the matter of drinking waters we have still to admit that chemistry fails to supply us with satisfactory reasons for their physiological activities but where application to the external surface is concerned we are dealing less with chemistry than with physics and we are therefore able to explain the results with considerable accuracy in terms of thermic, mechanical, and other forms of stimulation. The Nauheim waters as used for bathing contain, according to Weber,[3] "about 2 to 3 per cent. chloride of sodium, two to three per mille chloride of calcium, some bicarbonate of iron, and much carbonic acid gas," and they are applied at temperatures varying from 95·5° to 82° F.

The physiological effect of these baths, as may readily be understood from their stimulant constituents and their low temperature, is to increase blood pressure. It is also claimed that they exercise, by way of the cutaneous nerve endings, a reflex effect upon the centres which control the force and frequency of the cardiac systole, resulting in an increase of the former and a decrease in the latter. This is a claim which may in some degree safely be conceded to them; their chief effect, however, is that of increasing the intravascular tension. This has been denied by some writers who have not apparently understood that in so doing they were endeavouring to explain away the chief merit of a measure in whose cause they were appearing as enthusiastic champions. Increase of blood pressure, as everyone is aware, induces a slower and stronger cardiac systole, because the heart is stimulated to overcome the resistance. The duration of the baths is so managed that the stimulation is never allowed to approach the point of exhaustion; the effects are therefore maintained for a considerable time after its cause is removed. By repetition of the process these effects become increasingly pronounced owing to the heightened tone in the peripheral vessels induced by the cutaneous stimulation. We have, in fact, in these baths, as managed by a thoroughly experienced physician, a cycle of results almost exactly analogous to that produced by the action of digitalis, with this in favour of the baths that there is little danger of cumulative action or an overdose and none whatever of unpleasant consequences in the digestive tract. It is also true that the favourable results of the baths last much longer than the same results when secured by the use of the drug. In the light of this analogy it is not difficult to fix the limitations of the therapeutic value of the baths, which were, indeed, indicated by Sir William Broadbent[4] as long ago as 1897 in the following passage: "In cases of cardiac dilatation from loss of tone of the heart muscle after influenza or some depressing disease it (the system) may be of great service and effect a cure where drugs and other treatment have failed; in many cases of functional and neurotic heart disease, which are very common and are difficult to deal with, it may also give satisfactory results. In valvular disease it is, of course, unnecessary when compensation is established and no symptoms are present; when compensation has completely broken down it is not advisable as rest in bed and suitable treatment by other means will be more efficacious. In cases of mitral disease, more especially mitral stenosis, when compensation is just maintained with difficulty and when the degree of stenosis is such that increased contractile power of the right ventricle induced by digitalis would be useless or harmful, it may be of great service In aortic disease it is not advisable, owing to the risk of syncopal attacks, though when compensation is breaking down and mitral symptoms are present it may sometimes yield good results." These views are substantially supported by the latest writer on the subject,[5] who, though an enthusiast, tempers his enthusiasm with a very commendable and quite unusual amount of discretion. Dr. Leslie Thorne selects as examples of those cases for which permanent or pronounced benefit may be expected, the dilated, enfeebled, and irritable heart with unimpaired valves such as is common after influenza, typhoid fever, and other exhausting illness, the tobacco heart, and those with valvular disease in which from similar causes compensation is threatened; those cases, in fact, in which it is not only desirable but safe to increase the peripheral resistance so as to stimulate the heart to stronger and more efficient contraction.

---

[1] Diseases of the Heart and Aorta, p. 357.
[2] Ziemssen's Cyclopædia, 1884.
[3] The Mineral Waters and Health Resorts of Europe.

And here it is pertinent to observe that the mere presence of dilatation, irrespectively of its cause, does not, as is so often erroneously supposed, constitute an indication for the employment of the Nauheim treatment, any more than it constitutes an indication for the exhibition of digitalis. Such treatment is suitable only for those cases where the dilatation is but a part of a general asthenia, as after diseases like influenza; or when it is the result of acute overstrain, abuse of tobacco, chlorosis, or the "fatigue products" of Clifford Allbutt. Such conditions constitute in reality, however, a very small proportion of the cases of dilated heart which come under notice. There is no such thing as primary or idiopathic dilatation and where the dilatation is not due to such causes as those just mentioned it is the result of undue resistance in the systemic periphery. In such circumstances to stimulate the heart without removing the resistance is merely to flog an overtired horse and to hasten the impending collapse. Of course, the undue resistance in the periphery may be merely relative, in the sense that the normal tone of the systemic vessels may suffice to offer a degree of resistance to the crippled central organ which it is beyond the power of the latter efficiently to overcome. Such a state of matters not infrequently arises in hearts the integrity of whose valves has become impaired by rheumatism and other acute specific diseases, especially as the result of shock, anxiety, worry, and other nervous influences. In such cases, though the Nauheim treatment may do good, it may, unless it is applied with a great deal of care and circumspection, do an infinity of harm; for the increase of the intravascular tension, instead of affording the desired stimulus to the cardiac contractions, may very easily provide the last straw in the tale of the heart's burden. In such cases the exercises alone, combined with drug therapeutics, are very useful but the baths should be reserved to a later period and even then the patient should be confided to the care of a physician, preferably at a health resort, who is exceptionally experienced in their administration.

The treatment by Nauheim baths is thus quite unsuited to the great majority of cardiac disorders which present themselves to the physician and its indiscriminate recommendation, even where dilatation is the most prominent objective feature, is by no means free from danger. It is fortunately no longer necessary to combat the preposterous claims which were at one time advanced to the effect that these baths were capable of a favourable influence upon aneurysm and angina pectoris from whatever cause arising. The "accidents" which have resulted from an over-abundant faith in these claims have been sufficiently numerous and startling to give pause even to the enthusiasts. The real truth of the whole matter may be summed up in saying that, as a rule which admits of very few exceptions, spa treatment is not suited to organic circulatory disorders where compensation is imperfect and that functional circulatory disorders, though sometimes conspicuously amenable to effervescent baths, are usually much better and much more scientifically treated by means other than those which are commonly associated with Nauheim. In order to appreciate this position it is necessary to realise not only the true nature of the problem which cardiopaths are liable to present, but also the nature and the degree of assistance which is to be expected of health resort treatment. And, first, as to organic affections. In the presence of a real lesion of, say, the mitral orifice, which is adequately compensated, no treatment directed to the heart itself can possibly do any good and it may, by disturbing the balance which nature herself has established, very easily do a great deal of harm. If, therefore, interference is to have any character other than that of pernicious meddling it must be directed to lessening the amount of work which the heart is called upon to perform, while avoiding anything which may tend to produce relaxation of the crippled organ. We are generally told that this indication is best fulfilled by rest and a tonic *régime*, which is commonly interpreted to mean physical or recumbent rest and a generous dietary. Now, rest and a tonic *régime* undoubtedly constitute the primary and essential indications, but the rest should not be physical but physiological rest and the tone to be improved should be that of the whole organism and not that of one viscus only. The aim, in fact, should be to maintain the body in a high degree of what sportsmen call "training" or fitness, carefully avoiding anything approaching to over-training but eschewing more especially the far more dangerous opposite extreme of "softness." For the man with a compensated lesion at his mitral valve is, as it were, in a chronic state of running a mile race, and unless he is maintained in the height of such a degree of general physical fitness as his lesion allows he will certainly be overtaken by cardiac dilatation. If, on the one hand, he is given digitalis, Nauheim baths, and other measures directed exclusively to the heart itself, he is in danger of being over-trained; and if, on the other, he is allowed to resign himself to a sofa and bath-chair life, reinforced by a "supporting" alimentary *régime*, he is, as the saying goes, "beaten before he starts." It is scarcely an exaggeration to affirm that most cardiopaths are permitted to go wrong in one or other of these directions, and it is quite certain that the dangers of both may be very readily avoided by timely and regular recourse to a form of health resort treatment which, in place of being enthusiastic-

[4] Heart Disease, with Special Reference to Prognosis and Treatment, by Sir William Broadbent and Dr. J. F. Broadbent, second edition, 1900.

[5] The Nauheim Treatment of Chronic Diseases of the Heart, by Leslie Thorne Thorne, M.D. Baillière, Tindall, and Cox, 1904.

and specific, is sane, physiological, and orderly. Such treatment would aim at maintaining the normal balance between intake and output by regulation of the diet; by providing for efficient, while avoiding excessive, exercise; and, above all, by promoting adequate excretion—by doing, in fact, those things which ought to be done and by leaving undone those things which should be omitted.

It is easy to object that these things can be managed at home, but the sad truth is that they seldom or never are. And this is no reflection either upon medical attendant or patient. A person with a well compensated lesion does not feel ill. He is not properly speaking an invalid; he seldom wishes to be so regarded and when he does it is not desirable that he should be. In either case he generally follows a course of his own choosing or one which is suggested by some irresponsible person or persons and unless he is every now and again compelled into the paths of physiological righteousness troubles are certain to arise. Incomparably the best, the easiest, and the least exacting way of so compelling him is to send him annually to a suitable health resort and to place him under the care of an experienced and skilful physician. A properly equipped health resort exercises an educational, a disciplinary effect upon those who visit it for treatment. Rules are there habitually observed which at home are habitually broken, the importance of detail is inculcated, and the value of regularity is appreciated. Special facilities, such as baths, massage, mechanical apparatus, waters, graduated hill paths, and the like, are provided for carrying out the items of the treatment, more especially that most important of all items, adequate excretion by skin, bowels, and kidneys. It is often surprising to find with what docility, even amounting to eager coöperation, a patient who is refractory at home will submit himself to discipline as soon as he finds himself at a health resort. Moreover, at a properly selected spa some, at any rate, of the practising physicians may be regarded as exceptionally experienced in the kind and degree of "training" to which a patient should be subjected and they may, therefore, be trusted not only to elicit the best immediate results but also to indicate the paths by which the dreaded days of broken compensation and intercurrent disease may be most successfully avoided. A cardiopath, though by no means necessarily a doomed man, has nevertheless a very narrow margin of hygienic error and there can be no doubt that if such patients were at regular intervals subjected to the educational influence of suitable health-resort treatment that margin would be overstepped far less often than it is. An annual reminder of the dangers ahead and practical experience in the best means of avoiding them are truly conservative measures which, if more frequently resorted to, would lessen materially the necessity for the exhibition of digitalis and the excuse for the routine employment of Nauheim baths. It is not suggested that these baths ought not to be used in such cases. They have, on the contrary, a very valuable place among the means calculated to maintain a sound physiological balance. When combined with other measures they help to promote metabolism, to increase pulmonary expansion, and to stimulate renal excretion; and it is partly because their routine employment is liable to obscure their value in these directions that such employment is to be deprecated.

Such an annual educational course, while eminently suitable to adults, is conspicuously adapted to children. The development of the cardiopathic child is liable to be defective in proportion to the gravity of the valvular lesion. If that development is allowed to continue on defective lines, such, for example, as inadequate thoracic expansion, the defect ultimately reacts injuriously upon the crippled heart and a vicious circle is established. It is essential to the future well-being of the patient that the establishment of this vicious circle should be forestalled and prevented; and this can be accomplished by timely and intelligent health-resort treatment far more effectually than by any other means. The personal element in the spa physician, his tact, knowledge, and experience, always a question of the first importance, is here absolutely paramount. For as there are some kinds and degrees of defective development which are vicious, so there are others which are wholly beneficial. Nature rightly guards herself against a general growth of tissue which it will be beyond the power of the heart adequately to feed but in this effort of thrift she is liable to include such organs as the lungs and kidneys which are among the most powerful of the heart's potential allies. To know what to develop and how to develop it, and what to refrain from developing, is the part of an experienced and skilful physician who has opportunities for close observation together with ready access to the necessary means of treatment, both of which conditions are more readily and more completely fulfilled at a health resort than elsewhere.

In the stage of broken compensation, even where this is only just commencing, very little is to be expected of health-resort treatment and this little can usually be more efficiently obtained at home. Cardiopaths in this stage bear journeys very badly and this consideration should alone suffice to protect them from being hurried to health resorts, especially oversea, even supposing it to be the case that some exceptional benefit is to be anticipated from the treatment on arrival. In reality, however, no such benefit is to be anticipated. The only cases which afford any justification whatever for the recommendation of a distant health resort in such circumstances are those of mitral regurgitation in the very earliest stages of threatened compensation and the majority even of those are much better managed at home. Nothing but harm can come of sending patients affected with aortic regurgitation away from their surroundings, and there is no spa whose magical effects provide a sufficient excuse for subjecting a case of mitral stenosis with broken compensation to the fatigues of a long journey and the inevitable disappointments at the journey's end.

In connexion with so-called functional cardiac disorders it is necessary to remember that they are not primarily cardiac. Whether with Babcock[6] we regard them as expressions of a disorder of the nervous system or with Huchard[7] we agree to attribute them mainly to the digestive system, or whether we decline with Clifford Allbutt[8] to attach the responsibility to any particular system, it is obvious that the initial fault is to be sought not in the central but in some peripheral organ or organs. The simplest explanation, and one which has the merit of including all the known facts, is that these functional disorders are due to abnormalities of vaso-constriction and vaso-dilatation induced by the presence of poisonous matters in the blood stream. Of these, by far the most important are those which give rise to vaso-constriction with its necessary sequence of increased blood pressure and decreased blood-supply to important viscera, including the heart itself. The latter, though thus deprived of its normal amount of nourishment, is nevertheless called upon to perform additional work in order to overcome the increased peripheral resistance, with the very natural consequence of tachycardia, bradycardia, arrhythmia, and pseudo-anginal attacks. If these disturbances of function are not relieved by the removal of their cause organic impairment in the form of arterio-sclerosis, myocardial degeneration, dilatation, and valvular insufficiency or stenosis are liable to follow.

It is necessary then that these disorders should be treated in their earliest stages, in the stage of arterial spasm which has not as yet led to organic change, the stage of "presclerosis" of Huchard and his school. Unfortunately, there is no one symptom of this stage which is sufficiently characteristic to attract attention unless it be the presence of a high tension pulse, which, in the minds of some is so indissolubly connected with granular kidney that when other symptoms of this are absent no importance is attached to the altered state of the vessel. The complaint which brings the patient under observation is usually one of palpitation or præcordial distress combined not infrequently with attacks of giddiness. Dyspnœa is generally a pronounced symptom.[9] The surface is pale and the extremities, which are always cold, not infrequently "go dead." The urine is sometimes scanty and high coloured; sometimes it is the reverse; more often there is no regularity, the one state alternating with the other. The examination of the præcordial area which these symptoms naturally suggest reveals no increase of dulness and no murmur, but there is always an accentuated second sound to be heard at the aortic cartilage, and not infrequently a prolonged first sound at the apex. The degree of the accentuation of the second sound will vary with the amount of spasm and the propelling power of the cardiac muscle. It is sometimes absent, and then it will be found that all the sounds are muffled without being impure. A history of mental lethargy may often be elicited, together with other symptoms suggestive of inadequate vascular supply to important organs.[10]

Now the proper treatment of cases of this nature should obviously be directed to bringing about vaso-dilatation. Drugs such as nitro-glycerine and nitrite of amyl, though highly useful in an emergency, produce effects which are much too transient to be of lasting benefit. What is required is a permanent reduction of blood pressure, and this can only be secured by ridding the system of the toxins which are causing the vaso-constriction. To accomplish this time is required, and that time must be spent in carefully adjusting the habits of life to the threatening conditions, by regulating the diet so as to avoid as far as possible the introduction of fresh toxins, by promoting metabolism, and encouraging excretion. And these things must be done systematically, according to a definite scheme which permits only of such variations as the changing reactive powers of the patient demand. And they must be done efficiently—that is to say, in circumstances where the patient has little or no temptation to neglect his instructions and in a locality where all the necessary means for the regulation of diet, the promotion of metabolism, and the encouragement of excretion are ready to hand. In a word, the patient should be sent to a health resort. It may, of course, be possible to treat him in his ordinary surroundings, but at the very best this is an extremely difficult matter, at any rate at first, whereas at a spa everything is made easy and the habits there inculcated, when once acquired, have a reasonable chance of being continued under the various conditions of trial and temptation which home life is liable to present.

In deciding upon the respective claims of the numerous spas at which cardio vascular diseases may be treated on these lines it is necessary to take into consideration various factors, the majority of which it is beyond the scope of this paper to notice. There is, however, one general principle and a few practical details which may be mentioned in conclusion. The general principle is that any spa at which gout is properly treated is, potentially at any rate, a spa suitable to a cardiopath. The spa treatment of gout is directed mainly towards the promotion of metabolism and excretion and to the establishment of suitable habits, dietetic and hygienic, measures which, with slight differences in detail and degree, we have seen to dominate the rational treatment of cardiopathies, whether organic or functional. As qualifying this general principle, however, it is necessary to remember that physicians at "gouty" resorts are not, as a rule, in the habit of dealing with cardiac disorders, except in so far as these appear as complications or concomitants of the arthritic state, and that, furthermore, certain health resorts the waters of which are well adapted to the gouty have, so to speak, specialised in troubles of the cardio-vascular system, much in the same way and for the same obscure reason as Aachen has specialised in syphilis, Cauterets in throat affections, and Franzensbad in diseases peculiar to women Of those which have specialised in circulatory disorders Nauheim, of course, occupies the first place. The general merits of this spa have, however, become so obscured by its reputation for miraculous results that it seems a species of *lèse-majesté* to include it among those resorts at which such everyday matters as metabolism and excretion may suitably be promoted. When it has successfully passed through the trying ordeal of the fairy tale period, which well-meaning but indiscreet enthusiasts have imposed upon it, it will take its place, and that probably a high one, as a resort at which cardiopaths may be treated rationally and with discrimination. That time is not yet, however, and until it arrives he who would avoid heroics for his cardio-vascular patients would be well advised to send them elsewhere.

Of the home stations which are suitably equipped for the treatment of cardiopaths on the lines above indicated it would be invidious to draw any distinction between such well-appointed spas as Buxton, Bath, Harrogate, Leamington, Strathpeffer, and Llandrindod, all of which are "gouty" places and at which, in consequence, metabolism and excretion are well understood, but none of which have so far shown any tendency to specialise in cardio-vascular disorders. The only British spa to exhibit any such tendency up to the present is Llangammarch Wells,[11] but judged from the continental standard of comfort and the provision of amusement and distraction this must be regarded as a health resort *in posse* rather than *in esse*. Considerable improvements have, it is true, been effected there during the last 12 months, but if it is ever to take the position to which its barium waters entitle it, a position which on many grounds we all desire to see it occupy, the present local policy of *laissez faire* must be replaced by one of vigorous energy and enterprise.

In France, two places, Bourbon-Lancy and Evian, have long specialised in cardio-vascular complaints and one, Royat is in process of so doing. A curious and hitherto unexplained, but clinically well-founded specialism, that of disorders of the venous system, is also found among the French spas at Bagnoles de l'Orme in Normandy. At Bourbon-Lancy they approach the treatment of organic cardiac complaints from the standpoint of the rheumatic and other diatheses which gave them birth. While special care is taken to "train" the heart and to develop the lungs, the underlying habit of body receives the utmost attention with a view not only of ameliorating existing conditions, but more especially of providing against any recurrence of acute attacks For the waters of Bourbon-Lancy have a special value in the rheumatic diathesis. Wherein this value consists it is no more possible to say than it is to explain the undoubted efficacy of the waters of Contrexéville in renal affections. Inorganic chemistry has certainly no light to throw on the matter but here, as elsewhere, it is probable that radio-activity[12] and possibly some other forms of organic action may ultimately serve to explain the exact method of therapeutic effects the existence of which it is not possible to doubt. But, important as it is from the point of view of correcting the rheumatic tendency, the ingestion of the waters does not constitute the sole claim of this station to be regarded as one pre eminently suited to the rational—that is, the prophylactic treatment of rheumatic cardiopaths. This claim rests in some degree upon its admirable natural advantages, climatic and æsthetic, but in a very large measure upon the very complete equipment, balneary and mechanical, with which the station is provided.[13] More important still, however, is the fact that the physicians have special knowledge and very special experience in applying the waters, the baths, and the mechanical means to the peculiar needs of cardiac patients in such a way as to adjust the work of the heart to the nature and degree of its impairment, thus securing to the patient increased capacity for work and indefinite postponement of consequential evils. It is well to remember that there are no miracles at Bourbon-Lancy and that it is useless in consequence to send thither a patient whose lesion is uncompensated, or such as have definite arterio sclerosis, atheroma, or mitral stenosis of long standing. The cases from which the best results are to be expected, and these are often brilliant, are compensated organic lesions of rheumatic origin in children and young people, in whom it is still possible to adjust the general physical condition to the impaired cardiac capacity. At this station, in fact, they make a specialty not so much of the disease as of the patient. The lines on which Évian has specialised are rather different. Here they concern themselves chiefly with functional cardiac complaints, the *cardiopathies artérielles* of the French school, and this they do by promoting excretion, more especially the renal excretion, for which their waters are so admirably adapted.[14] In addition, however, they encourage the action of that most important emunctory the skin, and in order to promote elimination by this route they have provided themselves with a magnificent *établissement* which is fully equipped with all the means for modern balneary therapeutics and contains in addition the mechanical appliances which constitute so important an element in the rational treatment of cardiopaths. Functional cardiac complaints, more especially in the stage of spasm or pre sclerosis, induced by the

presence of some poison in the blood and manifested by high arterial tension and such symptoms as breathlessness, palpitation, tachycardia, arrhythmia, and others already referred to, are treated here on thoroughly rational and scientific lines. With a view of checking the manufacture of the poison diet is regulated and with the object of insuring its disposal metabolism is increased and excretion, renal and cutaneous, is vigorously promoted. Moreover, the real inwardness of his complaint is carefully impressed upon the patient who is given to understand that if he does not wish his functional troubles to progress towards organic disease, such as granular kidney, angina pectoris, and diabetes, to say nothing of heart disease proper, he must be careful to observe the hygienic rules in which, down to the minutest detail, he is there instructed and the advantages of which he very soon learns to appreciate.

Although France is, in Châtel-Guyon, Salins Moutiers, Chateau-neuf, St. Nectaire, and Royat, provided with several well-appointed spas the waters of which contain a great deal of carbonic acid gas, it is only the last named, and that quite recently, which has shown any tendency to specialise in the treatment of cardiac complaints. The action of effervescing baths not only upon cardiopaths but also upon healthy people has been here studied in great detail[15] and the conclusions arrived at are entirely in consonance with those of Broadbent[16] and other unprejudiced writers on the subject. Royat being originally a gouty spa, and being possessed of waters exceptionally rich in CO_2, it is eminently fitted both by nature and experience for the rational treatment of circulatory disorders. The place[17] is rather more bracing either than Bourbon-Lancy (800 feet) or Évian (1250 feet), being situated in a valley which runs east and west, 1500 feet above sea-level. The relative humidity is low and the surroundings are exceptionally agreeable. The close proximity of the large town of Clermont-Ferrand (one and a half miles) affords a source of interest to visitors which is not common at health resorts. For cases which are amenable to treatment on Nauheim lines in which Nauheim itself, from its moderate elevation (400 feet), its comparatively unsatisfactory climatic conditions, or from other considerations[18] is deemed unsuitable, Royat is very well adapted, and it is especially suited to such patients as require mildly bracing conditions in charming surroundings.

York-street, W.

SURGERY AT SEA: A CASE OF PERFORATING DUODENAL ULCER; OPERATION; RECOVERY.

By HUGH W. BAYLY, M.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.

ON April 27th, 1905, at noon, I was asked by Mr. Aubrey D. Knight, at that time the surgeon to the Royal Mail Steam Packet Company's ship *La Plata*, then three days out from Barbados on the homeward voyage, to meet him in consultation over a Government passenger (a soldier) who was suffering from severe abdominal pain. The history of the case was as follows. The patient, aged 24 years, had been suffering from "indigestion" for several years and said that he had many times been under treatment for "gastric ulcer" and had at one time been several weeks in hospital, when he had been placed on rectal feeding. He had several times had hæmatemesis, the last occasion being about three months previously. Since joining the ship his motions had been black. He was a bad sailor and had been seasick for 24 hours before I saw him. At 10.20 A.M. he had been seized with a sudden sharp pain situated about three inches to the right and at the level of the umbilicus.

I found the patient lying on his right side on a mattress on the floor of his cabin with his legs drawn up and in great pain and distress. On inspection the breathing was seen to be entirely thoracic and the abdominal walls were absolutely rigid. On percussion there was hyper-resonance over the right side of the abdomen but no loss of liver dulness. There was extreme tenderness on pressure over the whole of the right side of the abdomen but the left side was not so sensitive. The temperature was 96° F. and the pulse was 100, weak but regular, and not running. There had been no hæmatemesis.

I diagnosed perforating duodenal ulcer and advised immediate operation, but before proceeding to operation in the necessarily somewhat unfavourable circumstances I suggested to Mr. Knight the advisability of taking another opinion. He therefore asked Mr. G. W. Paterson, Government surgeon at Grenada, to see the case with us. Mr. Paterson considered that the case was either one of perforation of, or hæmorrhage from, a duodenal ulcer and as in his practice he had recently met with a case with very similar symptoms which turned out to be only hæmorrhage and recovered without operation he advised watching the case for four hours before proceeding to the somewhat desperate resource of abdominal section in a cabin on a rolling ship.

At 4 P.M., therefore, we saw the patient again and we then found that the pulse was 120 and that the temperature was normal, and that there was distinct distension of the right hypochondrium and right half of the epigastrium. We all agreed that surgical aid was now indicated and Mr. Knight requested Mr Paterson as the most experienced surgeon to undertake the operation. Mr. Paterson unfortunately was a bad sailor and subject to attacks of giddiness, so, though offering us the invaluable aid of his advice, experience, and assistance, asked me to operate. The ship's carpenter fixed up a board table two feet wide across the cabin, thus dividing it into two portions. Mr. Paterson, who kindly acted as my assistant, and Mr. Knight, who gave the anæsthetic, took the outside on the right of the patient, while I myself and the hospital assistant remained on the inner side of the table next to the door of the cabin. I made an incision in the middle line from the ensiform cartilage to an inch above the umbilicus and was somewhat hampered by the fact that there were only two scalpels available and that they had both been recently blunted by opening an abscess in the horny hand of a stoker. As soon as the peritoneal cavity was opened a considerable quantity of fluid escaped which, however, did not smell offensively. The ulcer was of about the size of a sixpence and was situated on the upper and anterior surface of the first part of the duodenum, almost encroaching on the pylorus. I first closed the ulcer with a purse string suture and then invaginated it with Lembert's sutures. I made a suprapubic pelvic drain and washed out the peritoneal cavity with normal saline solution and sponged it as well as I could, but the patient showed signs of collapse and I had to hurry over the peritoneal toilet and stitch the abdomen up quickly. I left a gauze drain at the site of the ulcer and another leading to the bottom of the pelvis. With the help of strychnine and ether hypodermically, a hot brandy and saline enema, and hot bottles the state of shock gradually passed off.

I should have liked to perform a gastro-jejunostomy but neither the condition of the patient nor the instruments at my disposal would allow of this and as there appeared to be plenty of room at the site of the ulcer I hoped the operation would not produce so serious a stenosis of the gut as to be of material importance. In 13 hours—viz., on the morning of the 28th—the temperature was 100° and I thought that it would be advisable to remove the gauze drains. As the patient, however, seemed very weak and as he had taken no nourishment for 24 hours before the operation owing to sea sickness, and as he had lost a considerable quantity of fluid *viâ* the peritoneum, I first transfused him with two pints of normal saline solution. I had no proper transfusion apparatus but with the help of a stomach-tube and an exploring needle, the point of which one of the engineers kindly filed off for me, an efficient substitute was soon made.

After the transfusion the pulse considerably improved and Mr. Knight gave an anæsthetic of equal parts of chloroform and ether and I removed the gauze drains. The upper wound was clean but a considerable amount of purulent material escaped from the suprapubic incision. I washed out the pelvis with normal saline solution and put in a rubber drainage tube. On the morning of April 29th I washed out the pelvis again but there was practically no pus and the patient was now taking half ounce doses of milk and water every half hour. In the afternoon the temperature rose to 101° and the pulse to 120, so as I suspected some accumulation of pus I examined the pelvis with the finger and washed it out again. I could not, however, find a pocket of pus but on the morning of the 30th when I dressed the patient about one ounce of pus escaped and the temperature fell to normal and the pulse to 90. The patient was now taking one ounce of milk and one of water alternately every quarter of an hour. In the afternoon we ran into a heavy gale and the ship rolled badly and the patient began to vomit considerable quantities of dark-green fluid. As he was subject to sea-sickness I could not be certain whether the vomiting was due to the sea or to peritonitis, so I gave him a quarter of a grain of morphine hypodermically every six hours and discontinued feeding by the mouth and substituted rectal feeding every four hours, together with an enema of a quarter of a pint of normal saline solution every six hours, given half an hour after the hypodermic of morphine.

[16] Loc. cit.

[17] Vide Journal of Balneology, October, 1904, p. 277.

[18] Consult McGregor Robertson's paper already mentioned.

On May 1st the vomiting continued but was less frequent, occurring about every four hours, but the temperature rose to 100° in the morning and 101° at night, when the pulse was 140 but regular and of fair strength considering his condition. The patient now was unable to retain the nutrient enemata and as he was still losing fluid by vomiting I again transfused him with two pints of normal saline solution. I also ordered a drachm of sulphate of magnesium in an ounce of water to be given every four hours till an action of the bowels had been produced; this occurred on the following morning and was very offensive. On the 2nd the sea moderated and I left off the morphine and rectal feeding and returned to feeding by the mouth, giving one ounce of milk and one ounce of soda-water every hour and the white of one egg made up to two ounces with water every four hours. The vomiting now was rather less frequent, occurring about once in five hours, but the amount vomited seemed to equal the quantity of nourishment taken.

On the morning of May 3rd the temperature was 99·5° and the pulse was 120. I removed the pelvic drain and washed out the pelvis every morning. In the afternoon we arrived at Plymouth and as the captain had kindly signalled at the Lizard for an ambulance to be in waiting at Plymouth I transferred the patient to the South Devon and East Cornwall Hospital. On the 18th, in reply to inquiries, I received a wire from the house surgeon: "Wounds still suppurating, general condition slightly improved;" and on July 10th: "Quite well, going out of hospital."

The Royal Mail Steam Packet Company carries a trained nurse on both its mail and intercolonial steamers and a trained male hospital assistant on its mail boats, and the *La Plata* was taking home as passengers two time-expired nurses from the intercolonial boats, and my best thanks are due to these ladies who devoted themselves entirely to the case and without whose willing and able assistance a successful result would probably not have been reached. My special thanks are also due to Mr. Paterson for his invaluable help. No doubt the fact that the patient had taken no food for the 24 hours previously to the perforation was a favourable factor.

I should like again to draw attention to the fact of the unreliability of loss of liver dulness as a symptom of perforation and to emphasise the importance of carrying a trained nurse on all large ocean-going passenger boats.

New Oxford and Cambridge Club.

ON THE BEHAVIOUR OF LEUCOCYTES IN MALIGNANT GROWTHS.

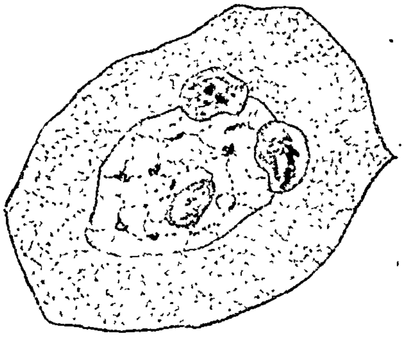
BY J. B. FARMER, F.R.S.,
J. E. S. MOORE, AND C. E. WALKER.

IN the present paper it is proposed to give an account of observations relating to the peculiar behaviour of leucocytes in very early examples of carcinoma in various parts of the human body. The phenomena described appear to be mainly, if not entirely, restricted to cancer in its earliest stages and not to occur in older growths, in metastases, or in grafts introduced into other individuals. Our observations at the present moment refer more especially to (1) a small primary rectal tumour, (2) an early case of chimney-sweep's cancer, and (3) an early epithelioma of the penis. In all of these the essential details in relation to the behaviour of the leucocytes are identical and suggest that we are here dealing with cytological phenomena peculiar to the earliest phases of the transmutation of normal tissue cells into cancerous elements.

It has frequently been noticed that round areas that are becoming cancerous there exists a marked activity among the leucocytes and the fact that cells in a cancerous area may contain leucocytic bodies within their cytoplasm has frequently been observed. The latter cases generally have been regarded either as phagocytic invasion of the leucocytes or as an indication that the cancer cells have assumed a phagocytic character with respect to the leucocytes. The results of the present investigations are not in accordance with either of these views. It was found in the rectal carcinoma above mentioned, for example, a growth that had hardly attained the size of a bean, that there was a very distinct zone of transition from the normal to the cancerous elements, round the periphery of the tumour; that is to say, a zone in which it was possible to pass, within the thickness of a few cells and almost insensibly, from elements that were merely actively dividing in the mucous layer, to cells that had assumed most markedly malignant characters. In this and other cases that we have examined we were irresistibly driven to the conclusion that the growth had not originated from a single cell or even from a few cells, but was being evolved by the direct conversion of a great many elements definitely functioning as mucous cells into those of a truly malignant type.

Immediately within this outer zone of the tumour the leucocytic crowding was most strikingly apparent and in a number of cells it was easy to discern the presence of leucocytes which had invaded the cytoplasm of the epithelial cells, where they stained readily as an inclusion. (Fig. 1.)

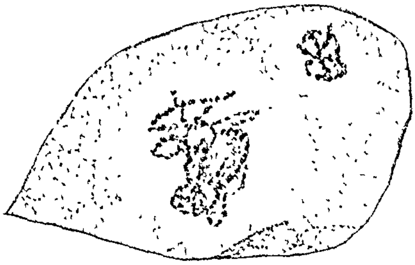
FIG. 1.



Tissue cell with two leucocytes lying in the cytoplasm adjacent to the nucleus.

This phenomenon did not occur in the adjacent healthy tissue, and we have ourselves been unable to trace it in inflammation produced by artificial means. But the most important, as well as the most singular, feature about the intrusion of the leucocytes into the tumour cells lies in the fact that neither the leucocyte nor the invaded tissue cell appears to be affected injuriously. Neither appears eventually to be destroyed, and it was soon found that many epithelial cells that were in phases of active division contained leucocytes that had been engulphed in their cytoplasm. In many instances it was found, moreover, that while the tissue cell was dividing mitotically the included leucocyte was also dividing in a similar manner and at the same time. (Figs. 2 and 3.) Both nuclei either passed

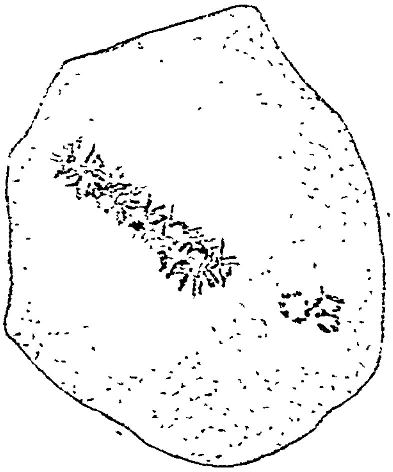
FIG. 2.



Tissue cell containing a leucocyte. Both nuclei are in prophase of division.

through their mitotic evolutions upon separate spindles, or the spindle figures became confused as is ordinarily the case in the first cleavage of the ovum.

FIG. 3.



Tissue cell containing a leucocyte. Both nuclei are dividing. The leucocyte is in a slightly earlier stage than tissue cell.

It is, we think, clear from the observations just recorded that a mixture of the chromosomes derived from the leucocyte and tissue cell respectively is distributed between the daughter nuclei resulting from the mitosis. In this way a complete disturbance of the normal chromosome constituents of the cell will be effected and the distribution must be of a qualitative as well as of a quantitative character. It may be well to indicate that if this process be compared to fertilisation there exists an important difference between true gametes and the cells concerned in this anomalous fusion. In the former (gametes) we are dealing with nuclei that have passed through the phases of maiosis (reduction), whereas there is no evidence at present to show that this is so in the case now under consideration. What its relation to the ultimate reduction that does occur in neoplastic cells may be is a subject for further investigation.

It may be pointed out that the fusion here described in no way corresponds with that union which has been stated to occur between the definite cancerous cells of certain neoplastic grafts.

In bringing this brief communication to a close we desire to express our indebtedness to the Imperial Cancer Research Fund for a grant in aid of our investigations.

CEREBRO-SPINAL MENINGITIS IN CEYLON.

BY ALDO CASTELLANI, M.D. FLORENCE,

LECTURER ON PATHOLOGY AT THE CEYLON MEDICAL COLLEGE.

OUR knowledge concerning the presence in the tropics of the cerebro-spinal meningitis due to the diplococcus intracellularis of Weichselbaum is very scanty; it may be therefore desirable to put on record two cases I had opportunity to study bacteriologically some months ago in this island. Both cases were Singhalese subjects and occurred at an interval of a few weeks. Both were brought to the hospital in a state of coma and died a few hours later before any complete clinical examination could be made. The post-mortem examination was held shortly after death and the macroscopical lesions found were practically identical in the two cases.

The meninges were thickened and opaque; the blood-vessels were greatly engorged. The entire cortex in both cases was covered with a thick purulent exudate; there was much pus along the larger fissures and sulci. On section the ventricles were found to be dilated; the cerebro-spinal fluid was turbid. A few cubic centimetres of this were collected and centrifuged. The microscopical examination of the sediment showed a very few mononuclear leucocytes, numerous polymorphonuclears, some of which were undergoing fatty degeneration, and a few macrophages. Some rare erythrocytes were present. Stained preparations showed numerous cocci. Most of these cocci were contained in the leucocytes and were arranged in couples; some were decidedly kidney-shaped, presenting an almost gonococcus-like appearance. A few were free and in rare instances were arranged in short chains. In preparations stained by Gram's method most of the cocci were not stained: here and there, however, it was possible to see a few which were not completely decolourised.

I tried to obtain cultures from the purulent exudation, the cerebro-spinal fluid, the pulp of the spleen, and the blood of the heart, using the ordinary laboratory media and also serum agar and blood agar. The media inoculated with the blood and the spleen juice remained sterile. Of the media inoculated with the purulent exudate and the cerebro-spinal liquid the agar, gelatin, broth, and peptone water did not show any growth: while the serum-agar and blood-agar tubes presented, after having been kept 24 hours at blood temperature, some small roundish translucid colonies showing some tendency to coalesce. Preparations from the colonies presented cocci in pairs and very short chains; the cocci were decolourised by Gram's method almost completely. Subcultures were made and frequently repeated. After several generations the organism became capable of growing well on ordinary media like agar-agar, gelatin, broth, &c. Moreover, the property being decolourised by Gram's method became less and less marked in solid media cultures, while it was retained by liquid media cultures. These characters of the meningococcus have been observed by many authors and lately well studied and minutely described by Lepierre.[1]

The organism in the first cultures obtained directly from the exudate and the cerebro-spinal fluid was very slightly virulent. Rabbits and guinea-pigs inoculated subcutaneously and intra-peritoneally all survived. Three rabbits were inoculated intravenously with an emulsion of two loopfuls each of blood agar culture in broth. They survived and practically did not show any signs of malaise. More successful was the inoculation of a similar emulsion under the dura mater. Of two rabbits so inoculated one died in two days; the other was ill for several days, refusing food and remaining in a state of sopor, but ultimately recovered. The necropsy of the rabbit which died showed a very marked injection of the meninges but no pus. Smears from the brain substance stained with diluted fuchsine contained many cocci, generally in pairs. From the brain substance, taken with all the aseptic precautions, pure cultures were easily obtained. The blood of the heart and the spleen pulp did not show any organisms when examined microscopically and all the media inoculated remained sterile.

By repeated passages through rabbits, using the subdural method, the organism became very virulent, being capable of killing rabbits by subcutaneous injections, this causing a general septicæmia so that the organism was easily grown from all the organs. Two rabbits were also inoculated under the dura mater with three drops each of the purulent exudation taken directly from the bodies. One showed signs of great malaise but survived; the other died in four days. The organism was present in the brain but not in the blood and spleen. The meninges were inflamed but no purulent exudation was present.

From all the characters of the organism found in these two cases of meningitis it was clear that I had really to do with the diplococcus intracellularis of Weichselbaum. This organism, discovered by Weichselbaum in 1887, was first considered by many observers as a simple variety of the streptococcus lanceolatus. Further investigation, however, clearly showed that it was quite a different species. Of the meningococcus several types have been described lately. Generally two types are admitted—the Weichselbaum type and the Jaeger-Heubner type. These two types are considered different species altogether by Weichselbaum himself, Albrecht Ghon, and others, while other authors (Concetti, Lepierre, and others) believe that the one type may pass into the other. The organism present in my cases was certainly a meningococcus of the true Weichselbaum type, as shown by the typical diplo hemispheric shape, the very slight virulence, the absence of growth (at first) in the usual media, and the discolouration by Gram's method, while the meningococcus of the Jaeger or Jaeger-Heubner type grows abundantly on the ordinary media, is frequently not decolourised by Gram's method, and is generally very virulent.

AN ANALYSIS OF 300 CONSECUTIVE GYNÆCOLOGICAL LAPAROTOMIES.

BY ARTHUR H. N. LEWERS, M.D. LOND., F.R.C.P. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

PART II. (*concluded*).[1]

THE notes of the first 150 cases of these 300 consecutive gynæcological laparotomies were published in THE LANCET last week. As I did previously, I would take the liberty of reminding readers that the notes should be read in connexion with the table published in THE LANCET of July 8th, 1905. p. 70.

CASE 151.—A double hydrosalpinx. The right tube was as thick as the wrist, the left tube being less enlarged. Adhesions were present in the pelvis

CASE 152.—A fibroid reaching up to the umbilicus. There were many old thin adhesions on the peritoneal surface of the uterus. There was a very perfect large tubo ovarian cyst on the right side, the outer (i.e., ovarian) part being of the size of a fœtal head at term. It lay in Douglas's pouch and was very adherent to the back of the uterus and rectum, it was removed without rupturing The left ovary, which was three times the normal size, was fixed in the pelvis and to the back of the uterus by extensive adhesions.

CASE 153.—Operation for generally contracted pelvis. This was the second pregnancy. The patient had been 24 hours in labour. The os was fully dilated; two attempts had been made outside the hospital to deliver with axis-traction forceps. The vulva was œdematous. The fœtal heart was distinct and was still beating when the child was extracted but the child could not be made to breathe. The true conjugate was about three and a quarter inches. The patient was said to have had one child before, a very small one delivered with great difficulty by forceps in Russia.

CASE 154.—A large tumour of the size of a uterus at eight months. The right ovary was removed with the tumour. A very large incision was made. There was a fibroid of the size of an orange growing from the posterior wall of the supravaginal cervix beneath the peritoneum; this had to be enucleated. The tumour weighed 9 pounds 10 ounces.

CASE 155.—A right pyosalpinx of the size of a duck's egg, which was adherent in the pelvis, to the rectum, and the back of the uterus. Pus escaped during removal. The left tube was enlarged and thickened and was adherent to the ovary; this did not contain pus. The peritoneum was washed out with saline solution.

CASE 156.—The external os was patulous, admitting the finger one inch or more. The canal was lined with malignant growth. The uterus was much less moveable than normal. The temperature was 104° F. on the first day the patient was examined. On opening the abdomen the pelvic organs were hidden by a roof of adherent intestine. On separating, the right ovary, which was of the size of a Tangerine orange, was gradually defined. The left ovary, which was of the size of a large walnut, was similarly separated from a bed of adhesions and complete removal of the uterus was performed. There were dermoid cysts of both ovaries. A gland of the size of an almond in shell was removed from the surface of the external iliac artery, it was not cancerous The abdominal wound broke down, but ultimately healed soundly.

CASE 157.—A left ovarian cyst of the size of an orange adherent in the pelvis. There was a right ovarian cyst of smaller size. Adhesions which were binding down the uterus in retroverted position were separated. A subperitoneal fibroid of the size of a plum at the fundus was not removed.

CASE 158.—A solid ovarian tumour had been diagnosed. On opening the abdomen the uterus and ovaries were seen to be quite normal. The sigmoid flexure lay directly under the wound and had a diameter of six inches. I called in a surgical colleague to see the case with me. At first it was thought that the tumour lay behind the sigmoid flexure and he made an attempt to enucleate it from behind. He soon concluded that the tumour was in the bowel and removed it by opening the bowel. It was a hard fæcal concretion of the size of a large cocoanut which had dilated the sigmoid flexure to the size mentioned. The patient had been in hospital a week and her bowels had acted well.

CASE 159.—A left ovarian cyst reaching to one inch above the umbilicus; it contained thick black fluid and required extensive enucleation The peritoneum was sutured over the region of enucleation. There was a right ovarian cyst of the size of a cocoanut which contained turbid yellowish fluid, not pus.

CASE 160. The tumour reached a hand's breadth above the umbilicus. There were multiple fibroids, some of which were calcified The left ovary was r moved with the uterus. The abdominal wall was very fat. The tumour weighed 4 pounds 10 ounces.

CASE 161.—The tumour reached nearly to the umbilicus to the right of the middle line The right Fallopian tube was found to be dilated to the size of a large orange and was adherent to parts around The fimbriated end of the tube was widely dilated. A macerated fœtus two and a half inches long came up among the clots removed. A mass of old clot of the size of the fist was adherent to the intestine and omentum and formed the greater part of the abdominal tumour noticed before operation. The right tube and ovary were removed. The left tube and ovary were normal and were not removed.

CASE 162.—The tumour reached nearly to the umbilicus. There was a double hydrosalpinx which was largest on the right side. There were numerous adhesions between the dilated tubes, the uterus, the rectum, and the pelvis.

CASE 163.—The uterus was of the size of a child's head (one year) and was enlarged by multiple fibroids undergoing mucoid degeneration. The right ovary and tube were removed with the tumour.

CASE 164.—An emergency operation in the night. There was a large quantity of blood and clot in the peritoneal cavity. The pregnancy was in the right Fallopian tube which had ruptured. The tube was removed. On examination afterwards the ovum was found in the tube with an amniotic cavity and a fœtus three quarters of an inch long. *Note.*—This patient was operated on by me on Sept 6th, 1901, for ruptured extra-uterine pregnancy in the left Fallopian tube Intravenous injections of salt solution were made during operation then.

CASE 165.—The uterus was retroverted and bound down by old adhesions and there were numerous adhesions binding down the uterine [illegible] ages were otherwise healthy. [illegible] were open After separati[illegible] but the uterus was stitched [illegible] wall. The operation was undertaken for chronic pain.

CASE 166.—The tumour was of the size of a uterus at six months One large fibroid had grown out into the left broad ligament, opening it out and raising the peritoneum from the left iliac fossa. Extensive enucleation was necessary. The left ovary was removed with the tumour. As the right ovary was cystic it was also removed. The patient died, probably from sepsis, on the fourth day. At the post-mortem examination nothing [illegible] te was found. There was very [illegible] appendages of very long standing. The whole of the pelvic contents were firmly matted together and separation was very difficult. The left Fallopian tube which contained thick turbid fluid, not pus, was first removed There was a left ovarian cyst of the size of a Tangerine orange which was removed. The removal of the right Fallopian tube caused most difficulty as it was firmly adherent, especially to the rectum and the vermiform appendix. The wall of the rectum was much damaged but its lumen was not opened. The right tube contained fœtid pus which escaped during removal. A fæcal fistula occurred a week after operation

CASE 168.—The tumour reached to the umbilicus and was softer than most fibroids. It was found to be fibroid undergoing mucoid degeneration. The right ovary was not removed. The tumour weighed three pounds.

CASE 169.—The tumour reached to the umbilicus. The fundus and the body of the uterus were not involved. The fibroid was a single one growing in the supravaginal cervix posteriorly. It had to be enucleated from the retroperitoneal "bed," from which there was much oozing. Both ovaries were removed with the uterus A gauze drain was inserted on account of the oozing The fibroid was extensively degenerated, section showing a substance like apple jelly in many places.

CASE 170.—A hard irregular tumour reaching to the ribs on the right side. There was much free [illegible] adhesions to the omentum, [illegible] dominal wall. The walls of [illegible] one or two places during removal, and papillomatous growth from the inside of the tumour escaped No secondary deposits were seen anywhere. The pedicle was broad but [illegible] ovary was healthy The peritoneum [illegible] A swelling of the left shoulder-joint [illegible] disappe[illegible] n convergent strabismus occurred. [illegible] eye changes were due to embolism [illegible]. The eyesight gradually improved.

CASE 171.—A left ovarian cyst of the size of a uterus at seven months. It had grown between the layers of the broad ligament and upwards behind the peritoneum Extensive enucleation was necessary Three or four inches of the left ureter were recognised closely applied to the deepest part of the cyst and required very careful separation. Many bleeding points in the retroperitoneal "bed" required tying The gap in the peritoneum was closed with fine silk. The tumour contained clear sticky fluid measuring 214 ounces.

CASE 172 The left Fallopian tube was enormously dilated to about the size of a child's head (one year) There were many adhesions to the intestine and the back of the uterus. One bleeding point on the back of the uterus required an encircling suture. A tubal mole was found in the tube.

CASE 173.—A right ovarian cyst of the size of a uterus at seven months with twisted pedicle. It was adherent to the abdominal wall, the intestine, and the omentum. It contained dark fluid; 108 ounces. The left ovary was healthy.

CASE 174.—The uterus was uniformly enlarged to the size of that of two to three months which was thought to be due to fibroids. It was merely gener[illegible] being found. The patient suffered from [illegible]

CASE 175.—[illegible] cyst of the size of a uterus at seven months. There were adhesions to the back of the uterus The pedicle was broad and was tied in sections. The right ovary, which was cystic and of the size of a duck's egg, was also removed.

CASE 176.—The patient had been married seven and a half years. The uterus was retroflexed and bound down by adhesions There was dyspareunia. At the operation the tubes were found to be healthy; [illegible] ovaries were separated and adhesions b[illegible] wall by one silkworm gut the uterus [illegible] suture pass[illegible] uterine appendages. There

CASE 177. [illegible] were many pel[illegible] those and seve[illegible] tubes were mu[illegible]

CASE 178.—A [illegible] The left tube was the larger and [illegible] to reach to the umbilicus The left tube con- into the cavity of the cyst formed by the ovary. The left tube contained pus and burst during removal. A small fibroid of the size of a walnut was removed from the right side of the fundus uteri. There were many pelvic adhesions. The peritoneum was washed out with salt solution. *N.B.*—The tumour was thought to be uterine fibroids before operation.

CASE 179.—A fibroid tumour of the left ovary of the size of a goose's egg which was adherent to the sigmoid flexure. The Fallopian tubes were normal. Part of the abdominal wound broke down but ultimately healed soundly.

---

[1] Part I. and the first portion of Part II. were published in THE LANCET of July 8th (p. 69) and 29th (p. 284), 1905, respectively.

CASE 180.—The tumour reached nearly to the umbilicus. There was an interstitial fibroid of the fundus and posterior uterine wall. The left ovary was removed with the tumour but the right ovary was not removed. Menorrhagia had been the chief symptom.

CASE 181. A left ovarian cyst which reached up to the umbilicus. It contained thin black fluid. The cyst burrowed between the layers of the broad ligament and had to be carefully enucleated. While doing this a portion of the left ureter came into view. There were adhesions to the intestine also. The right ovary was normal.

CASE 182.—A left ovarian cyst of the size of an orange which was very adherent in the pelvis and to the rectum. It contained dark fluid.

CASE 183.—A right pyosalpinx. On opening the abdomen the pelvic organs were seen to be roofed in by coils of intestine which were firmly adherent. On separating these it was found that the right Fallopian tube was greatly dilated and adherent everywhere, it contained fœtid pus and burst during removal. The uterus was firmly adherent to the rectum. During removal a hole was torn in the rectum. The patient died from shock in 24 hours.

CASE 184.—A multilocular left ovarian cyst containing bloody fluid and of the size of a child's head (one year), with twisted pedicle. There were adhesions to the intestine. The patient was four and a half months pregnant at the time of operation and did not abort after it. She was taken ill suddenly a few days before admission with symptoms of twisted pedicle.

CASE 185.—The left Fallopian tube was of the size of an orange and contained a tubal mole. The tube and ovary were removed. There were many adhesions to the intestine and in the pelvis. A small rupture had occurred at one part of the tube. There was a good deal of old blood clot in the pelvis.

CASE 186.—A double pyosalpinx. On the right side the tube had formed a tumour curiously twisted like a large whelk shell; it contained pus which could not be pressed out of the minute open end of the tube as this was closed in a valve-like manner by the tension of the fluid inside. The right ovary was removed with the tumour. The left tube was similar but smaller and was also removed. The left ovary was not removed. No tubercle bacilli were found in the pus.

CASE 187.—Both tubes were dilated and adherent to the ovaries and parts around.

CASE 188.—The tumour reached to the umbilicus and was thought to be a fibroid. On opening the abdomen free fluid was found. A soft, friable mass (like malignant ovarian) was seen growing from the anterior surface of the uterus. Hysterectomy was performed with difficulty as the broad ligaments were found to be thick and inelastic and apparently infiltrated by malignant growth. The patient died from peritonitis on the third day.

CASE 189.—Pregnancy in the right Fallopian tube. This showed no sign of rupture, it contained a fœtus two and a half inches long. The right ovary was not removed. This case must be regarded as "missed" tubal abortion.

CASE 190.—A tumour reaching rather above the umbilicus. There were multiple fibroids. The right ovary was removed with the tumour.

CASE 191.—Chronic inflammation of the uterine appendages. The right tube, which was adherent to the intestine, was removed with its ovary. The left tube was dilated, this was also removed. The left ovary was not removed. The tubes contained dark turbid fluid, not pus.

CASE 192.—A large multilocular ovarian cyst on the left side had burst and free fluid was found in the peritoneum. The pedicle was twisted. There was a similar smaller cyst of the right ovary. A lump was felt at the portal fissure of the liver of the size of a duck's egg, (?) malignant. No other secondary deposits were seen. The peritoneum was washed out with salt solution.

CASE 193.—A right ovarian cyst. There was a pyosalpinx on the left side which was firmly adherent to the uterus and rectum. The uterine tissue was friable and the uterus had to be removed. The patient died on the third day. The pyosalpinx burst during its removal.

CASE 194.—A hard, irregular tumour reaching to the umbilicus. Both tubes were dilated and therefore the uterine appendages were removed with the uterus. A part of one fibroid grew low down in the uterus and had to be enucleated.

CASE 195.—Both tubes were dilated and adherent to the ovaries and in the pelvis, especially on the left side of the rectum.

CASE 196.—A left ovarian cyst containing 15 pints of dark fluid. The right ovarian cyst was of the size of a duck's egg. There were no adhesions.

CASE 197.—A subperitoneal fibroid of the uterus of the size of a large orange with a narrow twisted pedicle. The tumour presented a blackish purple colour. Both ovaries were normal. On section of the tumour the surface generally was reddish black with circular yellow islets scattered over it.

CASE 198. The patient had been 36 hours in labour and the membranes had been ruptured 12 hours. A portion of the Fallopian tube was excised on each side. The child weighed 7 pounds 4 ounces. The mother and child did well. The patient's height was 4 feet 8 inches.

CASE 199.—An emergency operation. The abdomen was full of clot and fresh blood. The left Fallopian tube had ruptured and contained a tubal mole with an amniotic cavity of the size of a large walnut. The left tube and ovary were removed. The peritoneum was washed out with salt solution.

CASE 200.—A right multilocular ovarian cyst of the size of a uterus at term. There were no adhesions. The left ovary was healthy. The cyst contained 116 ounces of fluid.

CASE 201.—A large multilocular ovarian cyst reaching to three inches above the umbilicus. It contained thick glairy fluid. No adhesions were present.

CASE 202. A dermoid cyst of the left ovary of the size of a child's head (one year). This was removed without tapping. The right Fallopian tube, which was of the size of a forefinger, was closed at its fimbriated end and was adherent to the rectum, this was also removed. The right ovary was not removed.

CASE 203.—An ovarian cyst on the left side of the size of an orange. It was dense, adherent to the pelvis and to the rectum. The left Fallopian tube was dilated and it contained pus. The right tube was also dilated and closed, it was removed with part of the right ovary.

CASE 204. Fibroids forming a tumour which reached up to the umbilicus. The left ovarian cyst was of the size of an egg. The right ovary was normal except for a few adhesions to it which were broken down.

CASE 205.—A dilated left tube with an ovary somewhat cystic. It was very adherent in the pelvis. The right tube was similarly affected. Both tubes contained bloody fluid.

CASE 206.—A left ovarian cyst of the size of a duck's egg and a right ovarian cyst of the size of a hen's egg. Both contained dark tarry fluid and were more or less adherent in the pelvis. The uterus was moderately enlarged by multiple small fibroids, some of which were so placed as to interfere with the mobility of the uterus. The rectum was adherent to the back of the uterus.

CASE 207.—The patient was thought to be suffering from inflammation of the right uterine appendages. On opening the abdomen the ovaries and tubes were found to be healthy. the lump to the right was formed by a mass of omentum and intestine which was adherent to the appendix. My colleague, Mr. H. M. Rigby, took over the operation and removed the appendix.

CASE 208.—The patient was very ill on admission. It was thought that the tumour might be a large ovarian tumour with a twisted pedicle. Exploratory laparotomy was performed. The tumour was adherent to the abdominal wall half way to the umbilicus. The general peritoneal cavity was opened higher up. A solid red mass came into view, it had a smooth surface and occupied practically the whole of the abdomen. It presented a horizontal fissure and secondary fissures dividing it into lobes. It was like the spleen or the liver but these organs were not involved. About four inches of the descending colon was the only part of the intestine which was seen. The tumour passed into the pelvis and was firmly fixed there. None of the pelvic organs could be reached. Mr J. Hutchinson jun saw the case with me and considered it to be a retroperitoneal sarcoma. We both agreed that it was quite irremoveable. Nothing was attempted in the way of removal.

CASE 209.—One silkworm gut suture was put through the anterior surface of the uterus near the fundus, through the parietal peritoneum and the rectus on each side. The operation was for prolapse.

CASE 210. The left Fallopian tube contained pus and was adherent to a left ovarian cyst of the size of a Tangerine orange also containing pus. The right Fallopian tube was not closed or abnormal except for some filmy adhesions which were separated.

CASE 211. A flattened fœtus three inches long was found in an adventitious cavity in the left side of the pelvis with clot. The whole mass was of the size of a fœtal head at term. The left ovary was not removed. The inner part of the left tube was normal. The mass was certainly not in any part of the tube at the time of the operation. The right ovary and tube were normal.

CASE 212.—A fibroid growing out from each side of the uterus, causing a dumbbell shaped tumour. The right ovary was not removed. The tumour had caused retention of urine several times.

CASE 213.—A right hydrosalpinx larger than a large orange; this was sufficiently separated from the right ovary to allow of the latter being left. On the left side the dilated tube and ovary were both removed. There were a few film like adhesions about the dilated tubes.

CASE 214. The tumour was a large solitary interstitial fibroid of the anterior uterine wall. The mass was removed and weighed five and a half pounds. On section the tumour showed a surface like raw beef. The left ovary was not removed. The uterine cavity was between seven and eight inches long.

CASE 215. A left multilocular ovarian cyst reaching to the epigastric region. Tapping had to be performed three times before the cyst could be extracted. There was a right ovarian cyst of the size of a cocoanut; this had extensive adhesions in the pelvis which caused much trouble. Papillary growths were afterwards seen in the interior of both tumours.

CASE 216.—Pregnancy in the left tube which had just ruptured, causing a small amount of currant jelly clot in the pelvis on the left side. The left tube and ovary were removed. The ovum, a tubal mole, occupied the middle third of the tube, the fimbriated end of which was open and somewhat dilated. There was a rent in the posterior part of the tube. The right ovary and tube were healthy. Parotitis (right) came on within 24 hours but disappeared in a few days. I saw this patient on July 11th of the same year (1904) and she was then three and a half months pregnant normally.

CASE 217.—A large multilocular ovarian cyst of the size of a uterus at term, it was very friable. The other cyst was smaller and similar in kind. Free fluid was present in the peritoneum. There was a small patch at the bottom of Douglas's pouch suggestive of secondary deposit. The peritoneum was washed out with salt solution.

CASE 218.—The patient had been in hospital waiting for Cæsarean section, the intention being to operate as soon as labour began. On Jan 27th, 1904 I was told labour had begun and I at once operated. At the operation I found that the liquor amnii had all escaped and after extracting the body of the child through the ordinary uterine incision I could not get the head out as there was a well marked uterine contraction ring holding it round the neck. This ring had to be incised to get the child out. This, as might be expected, caused great hæmorrhage and in a place where it was difficult to stop it. This was done at last, but the patient died the same night. I found out afterwards that the waters had been noticed to have been coming away for four days. There was a generally contracted pelvis.

CASE 219.—A [illegible] the umbilicus [illegible] hed up to

CASE 220. A [illegible] A moveable knob of the size of an egg on the front of the tumour was subsequently found to be the middle third of the right Fallopian tube. This was adherent to the intestine omentum, and sigmoid flexure. The tube was bent down into the pelvis where its open, dilated, fimbriated extremity was fused with a mass of adhesions forming an adventitious cavity which was full of clot. The right tube was removed.

CASE 221. A right ovarian cyst of the size of a goose's egg. There were no adhesions. A part of the ovarian tissue beyond the cyst contained a well marked corpus luteum.

CASE 222. Fibroids reaching up to the umbilicus. The left ovary was adherent to the back of the uterus. It was separated from the adhesions but not removed. The right ovary was removed with the uterus. The fibroids had involved chiefly the upper part of the uterus. A small portion of the mucous membrane of the body of the uterus was probably left in the stump as the patient subsequently had a slight loss monthly. The patient was very anæmic before operation owing to menorrhagia.

CASE 223.—A fibroid growing from the left side of the uterus into the left broad ligament of the size of a fœtal head at seven months. This could not be brought up till the peritoneum had been incised and the tumour enucleated. The body of the uterus was not much altered. The left ovary and tube were removed with the tumour. The right ovary was not removed.

CASE 224.—A fibroid tumour of the uterus enlarging it to the size of a seven months gestation. After removing this carcinoma of the body extending into the cervical canal was found. The remainder of the cervix was removed from above. Both ovaries were slightly cystic.

CASE 225.—A dermoid cyst of the left ovary of the size of a cocoanut. This was removed without tapping; it was fairly adherent to the rectum. Some small fibroids in the uterus were not interfered with.

CASE 226.—A cystic subperitoneal fibroid of the size of a uterus at seven months; it was taken for an ovarian cyst before the operation. Omental adhesions were present. The right ovary was not removed. The fluid in the cyst was brownish.

CASE 227.—The symptoms dated from a confinement two months before the operation. The patient was a month in hospital before operation; she was feverish all the time. At the operation a right pyosalpinx was found; it was very adherent and burst during its removal. A left pyosalpinx was also present. Both tubes and ovaries were removed. The operation was very difficult. Convalescence was long. The patient went out on May 5th.

CASE 228.—The uterus was sutured to the abdominal wall by Kelly's method. A colporrhaphy (double) was performed three weeks later.

CASE 229.—A right unilocular ovarian cyst of the size of a hen's egg. The appendages were matted together; the tubes were thickened and adherent. A small subperitoneal fibroid at the fundus was not removed.

CASE 230.—A left dermoid cyst reaching to the umbilicus. There were adhesions to the omentum, the intestine, and in the pelvis. The right ovary and tube were healthy.

CASE 231.—A right ovarian cyst of the size of a uterus at six months. The wall was friable and broke in several places and papillomatous material from the interior escaped. The sigmoid flexure was adherent to the uterus and a hard ring-like thickening was felt in the sigmoid flexure, above which the descending colon was much dilated and evidently contained fæces. The opposite ovary was normal. After recovering from the ovariotomy the patient was transferred to the surgeon.

CASE 232.—A dermoid cyst of the right ovary of the size of a uterus at six months. There were adhesions to the intestine, omentum, and bladder. The left ovary and tube were also removed owing to some calcareous deposits being found in the ovary.

CASE 233.—A right multilocular ovarian cyst reaching to within one inch of the xiphoid cartilage. It contained 14 pints 12 ounces of fluid. The left ovary and tube were healthy. A fortnight after the operation a swelling was felt in the abdomen rising to the umbilicus and there was some bulging in Douglas's pouch. At this time for a week or so the temperature rose to 102° F. at night. All swelling disappeared in a week's time and the temperature became normal.

CASE 234.—The right Fallopian tube was much dilated and adherent to the ovary, also to the surrounding parts. On being opened it contained a tubal mole. The left ovary and tube were not removed. The case had been recognised as one of ectopic pregnancy and had been kept in hospital a month before operation, which was undertaken because pain persisted.

CASE 235.—A left tubal pregnancy; the fimbriated end was widely dilated and there was a large hæmatocele in the peritoneum. Attempted tubal abortion; there was no rupture of the tube. The tube was removed. This was a second ectopic pregnancy in the same patient, as she had been operated on two years before by Mr. Dean for tubal pregnancy on the right side. I was present at the operation. In opening the abdomen a second time the omentum and the small intestine were found adherent under the old scar.

CASE 236.—The uterus was enlarged by carcinoma of the body. Vaginal hysterectomy was attempted [illegible] time it was abandoned as it appeared imposs[illegible]ut from below. Abdominal panhysterectomy [illegible] deal of time was lost between the two operations. The patient had lost a good deal of blood and died from shock in 24 hours, in spite of intravenous injection of salt solution. I think that if I had begun with the abdominal operation the result would have been different.

CASE 237.—I had operated on this patient six months before for tubal pregnancy. On this occasion the pregnancy was in the left tube and there was a large amount of blood and clot in the peritoneal cavity. The ostium of the tube was widely dilated. The tube was removed. (This is the same case as No. 161 in this series.)

CASE 238.—A Cæsarean section (conservative); the child, a boy, was living. An attempt to sterilise the patient was made by excising loops of both tubes. The operation was performed about a week before full term. She had had three previous labours, two at term with forceps, the child on each occasion being stillborn, and one was induced at eight months, this child being also stillborn. She had a generally contracted pelvis; the conjugate was about three and a half to three and three-quarter inches.

CASE 239.—A left suppurating ovarian cyst of the size of an orange. There were numerous adhesions. Offensive pus escaped during removal.

CASE 240.—The operation was performed on account of menorrhagia. The sound passed for four and a quarter inches. There was a fibroid in the anterior wall of the uterus. The left ovary, which was slightly cystic, was removed with the uterus; the right ovary was not removed.

CASE 241.—Multiple fibroids. The tumour was of the size of a uterus at from three to four months. The right ovary was not removed; the left ovary, which was enlarged, was removed with the uterus.

CASE 242.—The left Fallopian tube was dilated and it contained a tubal mole. The tube was adherent to the rectum and the bladder, which stretched back over the dilated tube and had to be separated before the tube could be removed. The tube was dilated to the size of a goose's egg. The right appendages were normal.

CASE 243.—A right ovarian cyst of the size of an orange was adherent to the back of the uterus and in the pelvis. It contained bloody fluid. The left ovary and tube were matted by adhesions but these were separated and the left appendages were not removed. The ostium of the left tube was open, or it was opened [illegible] d's

CASE 244.—A right suppurating ovari[illegible] he head (one year). It was supposed to be a fibroid before op[illegible] The tumour patient had been feverish for some time before operation. The tumour was firmly adherent to the sigmoid flexure, the pelvis and the back of the uterus, and also to the omentum. The peritoneum was strippe off the right iliac vessels in separating the tumour, so that the righ ureter was exposed. The tumour was removed without bursting. I contained horribly offensive pus with flocculent green lumps. Th left ovary was normal. There was a subperitoneal fibroid of the size o a walnut at the fundus uteri.

CASE 245.—A large multilocular ovarian cyst (left) with twiste pedicle (one and a half turns in the same direction as the hands of watch). The tumour was adherent to the parietes, the large and smal intestine, the omentum, the bladder, and the uterus, as well as to th right uterine appendages. It contained black thin fluid. The peritoneun was washed out with salt solution. The last confinement had take place on Feb. 1st, 1904, and symptoms of twisted pedicle came on thre weeks later.

CASE 246.—A tumour of the size of the uterus at four months. Ther were interstitial and partly submucous fibroids, one of which wa undergoing cystic and mucoid change. The left ovary and tube wer not removed. The chief symptoms were menorrhagia and dys menorrhœa.

CASE 247.—Tubal pregnancy on the right side. A mass was found o the size of an orange, containing an amniotic sac and a fœtus two and half inches long. This lay partly free in the abdomen and partly in sa bounded by right tube and ovary. The latter contained the corpu luteum. The right tube and ovary were removed. The left ovar was not removed, but as the left tube was closed and dilated it wa removed. It contained bloody fluid. There was some free fluid in the peritoneum.

CASE 248.—The p[illegible] operation with a high [illegible] the abdomen and on [illegible] up. The left tube and [illegible] being universally adherent. It was uncertain whether pus was in the tube or outside it. The right uterine appendages being in a similar condition (though no pus was seen) were also removed. The patient died in 48 hours.

CASE 249.—A left ovarian cyst of the size of the uterus at seven months. It contained eight and a half pints of blood-stained fluid. There were no adhesions to the cyst, but the omentum stretched over it and was adherent to the anterior abdominal wall low down.

CASE 250.—The tumour reached up to the umbilicus. On operation it w[illegible] The peritoneum over the [illegible]e left iliac fossa directly and [illegible]t was enucleated from bene[illegible] the pus which it contained escaping freely. The left ureter was seen in relation with the base of the cyst. Neither the left ovary nor the tube was recognised as such. The right tube, dilated to the size of the thumb, was removed also with the right ovary.

CASE 251.—Operation for incomplete procidentia in a single girl where pessaries had failed.

CASE 252.—An emergency operation. The patient was admitted to hospital in a state of collapse and blanched, with a temperature of 96·5° F. and a pulse of 120. An intravenous infusion of saline fluid (five pints) was administered as the operation was begun. The peritoneum was full of blood and large clots. The pregnancy was in a rudimentary left uterine horn, which had ruptured. The amniotic sac protruded from the rent and had not burst until the operation. The fœtus was of the size at three months.

CASE 253.—The tumour reached to within two and a half inches of the umbilicus, to the right of the middle line. It was very tender. At the operation free blood and large clots were found in the peritoneum. The pregnancy was in the right tube, which had ruptured. The tube and ovary were removed.

CASE 254.—A left ovarian cyst rather larger than a cricket ball; it contained yellow turbid fluid. A small cyst in the right ovary was punctured and this ovary was left, as the patient particularly wished this done if possible.

CASE 255.—A right ovarian cyst. The pedicle was twisted one turn in the direction of the hands of a watch. It contained 26 pints 4 ounces of black fluid. There were no adhesions.

CASE 256.—At the operation numerous loose adhesions were found between the intestine, the bladder, and the omentum. These easily separated. Then a tumour of the size of a hen's egg was felt in the region of the left appendages. It was very adherent to the rectum and in the pelvis. Scissors were used partly in separating the tumour. Pus escaped as the tumour was being freed. The uterus was stitched up with one silkworm-gut suture as the patient had prolapse. She died nine days later from peritonitis.

CASE 257.—A left multilocular ovarian cyst containing jelly-like fluid. It reached two and a half inches above the umbilicus. There were no adhesions. [illegible] The

CASE 258.—A flattened and [illegible] true conjugate was estimated [illegible] operation was performed a we[illegible] expected. No attempt was made to sterilise the pati[illegible] was under the incision into the uterus. At a previous labour on July 10th, 1902, delivery was accomplished by cephalotripsy.

CASE 259.—The tumour was of the size of the uterus at three to four months. It had caused retention of urine several times. After removal the fibroid was found to be undergoing mucoid change. Both appendages were removed with the uterus. The left ovary was slightly cystic.

CASE 260.—A tumour of the size of a uterus at three months. There was an interstitial fibroid at the fundus undergoing marked cystic and mucoid change; the spaces on section were filled with jelly. Both Fallopian tubes were thickened and closed. The right appendages and left tube were removed with the uterus. The left ovary was not removed. The patient had had dysmenorrhœa and menorrhagia for a long time and was very anæmic at the time of the operation.

CASE 261.—A multilocular ovarian cyst on each side of the size of a child's head (one year). There was a large quantity of free fluid in the peritoneum at the operation. One cyst had burst before the operation. The walls of the cysts were very friable and contained yellowish fluid. No adhesions were present. The patient was four and a half months pregnant at the [illegible] and she miscarried within 24 hours. It was o[illegible] of a uterus at

CASE 262.—A [illegible] ortions of the eight months, a relatively large proportion [illegible] The fluid in tumour really consisting of a multitude of small cysts.

the cysts would not flow through the cannula. The uterus, which was moderately enlarged by fibroids, was not interfered with.

CASE 263.—A hard tumour, thought to be a solid ovarian; evidently calcified in parts. At the operation an oval tumour about three inches long by from one to two inches broad was found imbedded in adhesions in Douglas's pouch. Its surface was calcified. On section it showed a grey leather-like surface. The ovaries and uterus were not involved by adhesions or connected with the tumour in any way.

CASE 264.—A right multilocular ovarian cyst of the size of a child's head. There were no adhesions. The left ovary was healthy.

CASE 265.—Chronic inflammation of the uterine appendages; both tubes were closed and dilated to the size of a finger and were densely adherent in the pelvis. The pain dated from a confinement nine years before.

CASE 266.—Multiple fibroids. There was one subperitoneal fibroid of the size of a fœtal head, which grew from the fundus and lay in the pelvis adherent there by recent adhesions. This fibroid on section showed softening and on scraping the surface material like cream cheese came away. The right ovarian cyst was of the size of a hen's egg; this was removed with the uterus. The left ovary was not removed.

CASE 267.—On opening the abdomen a considerable amount of free fluid was found. A cystic tumour was seen springing from the right side of the pelvis, it was more or less fixed. On inspection of the deep aspect of the tumour a large papillary mass was found about the middle of the lumbar spine. This projected freely into the peritoneal cavity and had infected the intestine and other parts where growths of a similar nature were seen. The cyst burst during this investigation. Nothing further was done as the growths were obviously malignant. The patient died eight days later.

CASE 268.—A left tubo-ovarian cyst containing fœtid green pus. The outer (ovarian) part of the cyst, which was of the size of an orange, burst while getting it up. There were many adhesions in the pelvis. The peritoneum was washed out twice with salt solution.

CASE 269.—A right multilocular ovarian cyst of the size of a fœtal head. There were no papillomatous growths on the inner surface. The left Fallopian tube was thickened and adherent at the back of the broad ligament. This also was removed; it was found to contain blood clot.

CASE 270.—A left ovarian cyst reaching to the umbilicus. It had burst before the operation and there was chocolate-coloured free fluid in the peritoneum. The uterus, which was considerably enlarged by multiple fibroids, was also removed. The right ovary and tube were not removed.

CASE 271.—At the operation there was much recent blood in the peritoneum. It was a right tubal pregnancy. The tube had ruptured within one inch of its fimbriated extremity, which was open. The right ovary contained a well marked corpus luteum. The right tube and ovary were removed. The peritoneum was washed out with salt solution. The left ovary and tube were healthy. The patient was very anæmic.

CASE 272.—The operation was performed for uterine prolapse.

CASE 273.—Ovariotomy (double).

CASE 274.—A dermoid cyst of the left ovary reaching up to the umbilicus. The pedicle was twisted one and a half times in a direction opposite to that of the hands of a watch. There was intense congestion beyond the twist. Also a dermoid of the right ovary of the size of a potato. There was a little free fluid in the abdomen. There were no adhesions. Both tumours were removed entire. The pulse was 140 before operation and the temperature was 101·4° F.

CASE 275.—An operation had been performed four years previously by another operator in the country. He had only removed part of the tumour, leaving all the pelvic portion and presumably suturing the cyst to the abdominal wall. The patient had had a sinus from three to four inches deep, discharging freely ever since. I reopened the abdomen, having previously tied up the mouth of the sinus, and removed the rest of the tumour which was of the size of half a cocoanut. It was densely adherent to the rectum and the uterus. Two inches of the right ureter were exposed in dissecting up the tumour. The tumour was more or less solid and suggested malignancy, but I heard that the operator four years before had said that the tumour seemed malignant, so perhaps it may not prove so. The patient now is quite well and has no sinus.

CASE 276.—A large right ovarian cyst. It contained 21½ pints of greenish fluid. There were no papillary growths nor were there adhesions. The left ovary was healthy.

CASE 277.—A left tubo-ovarian cyst containing three-quarters of a pint of thin yellow fluid. The area of the tumour formed by ovarian tissue was well shown by a clearly defined white line. The right ovary was normal.

CASE 278.—The tumour reached to the umbilicus. The right ovary was cystic and was removed with the uterus. The right appendages were adherent to the uterus. The left ovary was not removed.

CASE 279.—A solid tumour occupying the greater part of the abdomen. At the operation it was found to be a large subperitoneal fibroid connected with the fundus uteri by a pedicle half as thick as the wrist. To the posterior (under) surface of the tumour about 12 inches of small intestine and mesentery were closely adherent and required very careful separation and the bleeding points on the intestine several ligatures. During this operation an indiarubber cord was tied round the pedicle of the tumour, as its surface was [illegible] the adhesions were [illegible] freely. The body of the uterus and the ovaries were not interfered with. The tumour weighed 12 pounds.

CASE 280.—A year previously the patient had had an incision made [illegible] in the left iliac region. Pus had come out and had continued to be discharged freely till the time when she came under my observation. With Case 275 in mind I thought it possible to deal with it. At the operation the sinus was found to be walled in by adherent bowel, it led to a portion of the left tube and ovary. The sinus was [illegible] in communication with the general peritoneal cavity. A right pyosalpinx and ovary were removed at the same time. The patient died from peritonitis in three days.

CASE 281.—Pregnancy in the right Fallopian tube. This was adherent in the pelvis. Its fimbriated end was closed. There was no free blood in the peritoneum. The right tube contained a tubal mole and was removed with the right ovary which contained a corpus luteum.

CASE 282.—Chronic inflammation of the right Fallopian tube and ovary. These were adherent in the pelvis. The uterus was bound down in the position of retroflexion by old adhesions. These were separated and the right tube and ovary were removed. Some small fibroids in the uterus were not removed. The operation was undertaken for chronic pain.

CASE 283.—The body of the uterus with a fibroid in the fundus was removed. The ovaries were not removed. After suturing the peritoneum over the cervical stump this was sutured to the abdominal wall as the patient had had prolapse.

CASE 284.—The tumour reached up to the umbilicus. The right ovary was removed with the uterus. The left ovary was not removed. (Chronic pain and menorrhagia.)

CASE 285.—A large left ovarian cyst bigger than a uterus at term. It had grown under the peritoneum and had completely separated the layers of the left broad ligament. The transverse colon was in front of, and adherent to, the tumour. Several inches of the left ureter were dissected from the base of the cyst which required extensive enucleation. The cyst contained thin black fluid. The abdominal wall was very fat.

CASE 286.—An irregular hard tumour reaching nearly to the umbilicus. At the operation there was found a subperitoneal fibroid at the fundus and an interstitial fibroid of the anterior uterine wall. The ovaries were not removed. (Menorrhagia and dysmenorrhœa.)

CASE 287.—A left multilocular ovarian cyst reaching to the epigastric region and causing great abdominal distension. It contained 20 pints 15 ounces of fluid. One portion of the cyst was composed of solid tissue like that of a fibroid, this had been felt in Douglas's pouch. There were adhesions to the omentum.

CASE 288.—A left ovarian cyst reaching to a hand's breadth above the umbilicus. It contained 11 pints 4 ounces of thin yellowish fluid. The right ovary was normal.

CASE 289.—A tumour reaching half way to the umbilicus. There were interstitial fibroids at the fundus and in the posterior uterine wall. The ovaries were not removed.

CASE 290.—A hard, irregular tumour reaching to above the umbilicus. The catamenia had ceased for five years. For the last few months the patient had had several slight losses of blood. On opening the abdomen a good deal of free fluid was found. Numerous secondary malignant growths were seen at various parts of the peritoneum. The tumour being obviously malignant the wound was closed.

CASE 291.—A hard, irregular tumour reaching to the ribs on the left side. Œdema of both legs was present. The deeper portion of the uterus and fibroids in it could not be got up till the peritoneum had been incised and this part of the mass had been enucleated. There were no adhesions. There was no trace of the right uterine appendages. The left ovary was not removed. The mass removed weighed 4 pounds 5 ounces.

CASE 292.—A tumour reaching to the umbilicus. Fibroids. One large interstitial fibroid lay in the supravaginal cervix and could not be brought up till the peritoneum had been incised and enucleation performed. This left a large raw surface with many bleeding points, to control which many encircling sutures were used. The left ovary was not removed.

CASE 293.—A right multilocular ovarian cyst reaching to the xiphoid cartilage. It contained 15 pints of dark fluid. The pedicle was twisted. There were adhesions to the abdominal wall and omentum. The left ovary was normal. There was œdema of the vulva before the operation.

CASE 294.—A right ovarian cyst reaching up to the umbilicus. On tapping it evidently contained papillary growths. Some pelvic adhesions were present. At one place there was a papillary growth on the outer surface of the right tumour. There was a left ovarian cyst of the size of a cocoanut, partly glandular, partly papilliferous. There were papillary growths of the size of shot on the intestine and at various points over the pelvic peritoneum. The uterus was slightly enlarged by small fibroids.

CASE 295.—Ovarian cysts of the size of large apples, one papillomatous on the outside. The left one was rather adherent in the pelvis. A lobulated subperitoneal fibroid was the chief tumour. Myomectomy was tried but the pedicle seemed to be unsafe, so hysterectomy was performed. Some other fibroids were found in the uterus. There was some free fluid in the peritoneum.

CASE 296.—The tumour in the abdomen reached to within one and a half inches of the umbilicus. There was a right ovarian cyst with twisted pedicle and many close adhesions to the small intestine. The left ovary was normal.

CASE 297.—A left ovarian cyst of the size of an egg; it was adherent to the rectum. The right ovary was healthy.

CASE 298.—A right multilocular ovarian cyst reaching three fingers' breadth above the umbilicus. The fluid would not pass through the cannula. There were some adhesions and while separating these the cyst burst.

CASE 299.—Both Fallopian tubes were dilated and closed externally and were adherent to the ovaries and the parts around. The left tube contained turbid thick fluid. The left ovary, which was enlarged to the size of a bantam's egg, contained half an ounce of greenish pus. The right tube contained yellowish green pus.

CASE 300.—Exploratory laparotomy in a case of carcinoma of the body of the uterus. Numerous secondary growths were found at various parts of the peritoneum remote from the uterus, therefore the wound was closed.

A CASE OF BLACKWATER FEVER.

By EDWARD S. CRISPIN, M.R.C.S. Eng., L.R.C.P. Lond.,
MEDICAL INSPECTOR, SUDAN CIVIL SERVICE.

THE following case of hæmoglobinuric fever may be of some interest, partly owing to its comparative rarity and partly owing to the fact that it is seldom, in the tropics, that so thorough an examination of the blood and urine can be made as was done in this case by my colleague, Dr. A. Balfour, director of the Wellcome laboratories in the Gordon College, Khartoum, to whose assistance I am much indebted.

The patient had had a previous attack of blackwater fever about eight years ago, which was probably contracted in Central Africa and which developed in this country. He had had repeated attacks of malarial fever during the last four months—the rainy season up the Blue Nile—which he told me he did not trouble much about; he took quinine often in large doses up to 60 grains in a day. On Oct. 2nd he had apparently an ordinary attack of malaria. On the 3rd hæmoglobinuria commenced. The patient was rather alarmed owing to his previous attack. He was seen by an Egyptian practitioner. His bowels were opened and he passed a large quantity of urine which was very dark, almost black, in colour. The urine was not examined microscopically or spectroscopically nor was the patient's blood examined, as there was no good microscope in the station The morning temperature was 101° F. and that of the evening 103°. On the 4th the condition of the patient was the same as on the previous day. He was reported to have passed 1900 cubic centimetres of urine in the last 24 hours which was almost black in colour. The temperature in the morning was 100·6°, rising to 105° in the afternoon and dropping to 103° in the evening. He was given a hypodermic injection (10 grains) of quinine in the morning and in the evening. On the 5th a similar condition prevailed. He was first seen by me at 6.30 P.M., when he was exceedingly blanched, with lips quite yellow. There was distinct jaundice though not deep in colour and frequent vomiting occurred, chiefly of bile. He was passing a large quantity of very dark urine and had very urgent desire to micturate but there was no pain in the loins. There was a good deal of headache and the patient was very restless and had had no sleep for the last two nights; the pulse was very fair. At about 7 P.M., contrary to orders, he got up to use a night stool and fainted; on coming round he was seized with a most severe attack of dyspnœa, with acute anginal pain over the cardiac region. I applied the only remedy at hand—a mustard leaf—which gave almost instant relief. He was taking very little nourishment but drinking a quantity of soda water and some champagne. The injection of ten grains of quinine was repeated morning and evening. The bowels were opened three times. The temperature in the morning was 100° and in the evening it was 102°. Ten grains of sulphonal (all that was available) were given with no result. Two grains of calomel were also given. On the 6th the patient was carried on to a steamer at 6.30 A.M. to go to Khartoum. No medicine was given on the journey. Milk and soda water and Benger's food were given every hour in small quantities and were well taken. There was no vomiting; there was some hiccough. The temperature was taken every two hours and only varied from 101·4° to 102°. The patient passed a great deal of urine, about eight times on the journey. I thought that that passed in the afternoon was of a lighter colour but could only judge by pouring it overboard. We arrived at Khartoum at about 6.30 P.M after 12 hours' journey. The patient had complained rather of the throbbing of the engines but had stood the journey well. He was most carefully wrapped up and screened from any chance of a draught on the journey. His bowels were not opened till after his arrival in hospital. He was given 20 grains of sulphonal at about 6 30 P M and five grains of calomel at about 10 P M. No more quinine was given. He still had a good deal of hiccough. On the 7th he had had a very fair night. He was rather delirious all day and seemed not to recognise anyone. He took nourishment very well—milk, soda water, Benger's food, barley water, and brandy (three ounces). Examination of the urine of the previous night resulted thus: it was hardly blood-stained; it gave a slight blood reaction; it was acid and contained some albumin; the sediment consisted of degenerated red blood corpuscles, numerous blood and epithelial casts, and tailed cells from the renal pelvis. Examination of the blood films taken the previous night was as follows: there were no parasites; there was marked degeneration of red corpuscles which stained badly and were vacuolated. Poikilocytes were present, as well as many polymorphonuclear leucocytes and blood plates. The patient had a weak pulse, was very restless, and had a good deal of hiccough. In the morning a pint of warm salt solution was injected into the rectum and half of it was retained. Two pints were similarly injected in the evening, one being retained. The patient passed a good deal of urine. His pulse averaged about 124; it was thin and compressible. His temperature varied from 100·8° to 101·2°. He was given bicarbonate of sodium (10 grains) four times in the day. On Oct. 8th he had had a bad night but was less delirious. He passed a number of small irritating stools during the night and all the day. There was no undigested milk in the stools. The rectum was washed out with an enema of warm water. He was still taking nourishment uncommonly well. There was no vomiting but still a good deal of hiccough. The blood contained no parasites. The urine showed a trace of albumin but no blood and very few casts and epithelial cells; it was very acid and full of uric acid crystals. The temperature varied from 101·4° to 102·4°. The pulse averaged about 120 and was weak. The patient was frequently sponged with tepid water and given some bicarbonate of potassium (15 grains) three times in the day. His general condition seemed improved. The urine was free from hæmoglobin, but his temperature was higher than on the previous day and he had a good deal of hiccough and diarrhœa. The jaundice and anæmia remained the same. On Oct 9th he had passed some irritating stools during the night. He was given half an ounce of Kutnow's powder. He was less delirious but the hiccough continued. There were no parasites but some myelocytes were present in the blood. There was a quantity of uric acid in the urine. The temperature at 7 A.M. was 101·8°, at 11 A.M. it was 101·2°, and at 3 P.M. it was 103°. The patient seemed distinctly worse but I was not sent for. The temperature at 6.30 P.M. was 104° when the patient was seen by me. The pulse was 124 and soft. He was much worse; he was given a subcutaneous injection of quinine (seven grains) and sponged with tepid water. The temperature at 8 P.M. was 103·4°; at 9.30 P.M. it was 104·4°. He was then put in a warm pack for 20 minutes and afterwards wrapped in hot blankets for an hour. He did not stand the pack at all well, complained bitterly, and was with difficulty prevented from tearing the blankets off. He was given another hypodermic injection of quinine (seven grains) and a feed of hot Benger's food with an ounce of brandy. Only slight reaction of the skin was produced At 10.30 P.M. his pulse was very weak and he was transfused with a pint of warm salt solution (one drachm to the pint) into the cellular tissue of the side and a hypodermic injection of strychnine (five minims) was given. At 11 P.M. the pulse was a little better and the temperature was 103°. His arms and face were then sponged with iced water which seemed most soothing. On Oct. 10th at 1 A.M. his temperature had dropped to 102·6° and he was dozing. At 2.30 A.M., while dozing, a sudden change took place and he died very quickly.

No thorough post-mortem examination was made but a portion of the liver and the spleen were examined by Dr. Balfour with the following result. The spleen: macroscopically its consistence was almost fluid; it was dark purple in colour; microscopically there were no parasites present and very little trace of malarial pigment. The general condition was somewhat like that found in splenic anæmia. The liver: macroscopically it was of a yellow, shrunken consistence, like leather; microscopically there were cloudy swelling, areas of degeneration, and atrophy of the hepatic cells; it was studded with yellow pigment; there was scarcely any trace of true malarial pigment. Slight cirrhosis was present but there were no parasites.

Remarks—I think there is no doubt that we have here a case of hæmoglobinuric or blackwater fever. The symptoms of hæmoglobinuria, icterus, biliary vomiting, and acute anæmia occurring during an attack of malarial fever are typical and yet post mortem we find only a trace of malarial pigment in the liver or spleen, the condition of the former being somewhat similar to that of a case of acute yellow atrophy of the liver. This naturally brings up the question of the real connexion between hæmoglobinuric fever and malarial fever and the administration of quinine. We have a patient from a malarial district having frequent attacks of malarial fever, during one of which hæmoglobinuria occurs. In the absence of any means of examining the blood for parasites the administration of quinine was obviously indicated and in this case ten grains were injected four times over a period of two days. They cannot in this case have increased the hæmoglobinuria as that ceased within 24 hours of the last injection.

It is a great pity no film of blood was taken for future examination before the first injection of quinine. It was noticed that very extensive bruising occurred at the site of the injections, but I think the injections, none of which were administered by me, were given subcutaneously instead of intramuscularly.

In all cases of severe malarial fever there is a great liberation of hæmoglobin which is precipitated in the form of yellow pigment in the liver; if this is still more excessive hæmoglobinuria is produced. This liberation of hæmoglobin cannot be simply from the infected corpuscles as it is far in excess of the number of infected corpuscles, continues after no parasites can be found in the blood, and non-infected corpuscles are found deficient of hæmoglobin. This bears out Sir Patrick Manson's theory that part of the hæmoglobin only is derived from these infected corpuscles which when sporulation occurs set free some toxin which is able to liberate hæmoglobin from uninfected corpuscles. This would account for the continuation of the hæmoglobinuria when there are no parasites in the blood.

How long does this toxic action last after parasites are absent from the blood? In this case the first specimen of blood examined was taken on the night of Oct. 6th and no parasites were found though at this time there was hæmoglobinuria. 24 hours later there was a trace of albumin but no hæmoglobinuria. Unfortunately, we are unable to say whether there were parasites in the blood on the 3rd, 4th, or 5th. With the cessation of hæmoglobinuria on Oct. 7th one would expect a more marked improvement than was the case if the toxin was only a liberator of hæmoglobin. May it not have some other toxic effect, or to what was the continuation of the fever due and the severe recurrence of fever on Oct. 9th? There had then been no parasites found in the blood for four days, nor were any found in the liver or spleen a day later. Yet on the assumption that the recurrence of fever on the 9th must be malarial in origin the injections of quinine were repeated.

This recurrence of fever in a patient, weak and exhausted from this drain of hæmoglobin, was the cause of death, though it cannot be called hyperpyrexia. The temperature went up to over 104° but was to a certain extent controlled by treatment. The least depressing methods of diaphoresis were employed—e.g., ice-sponging and wet pack accompanied with stimulants, brandy, strychnine, and saline infusion. No diaphoretic drugs were used except quinine. Free passage of urine and the absence of all renal pain were hopeful signs but I consider the persistent hiccough a useful sign for an unfavourable prognosis. I have seen no previous mention made of the great excess of uric acid crystals in the urine.

The treatment seems unsatisfactory. I did not understand the rationale of the treatment by large doses of calomel or chloroform pushed to intoxication, so these were not given. Quinine was given for the reasons mentioned. Other treatment was purely symptomatic. The treatment by bicarbonate of sodium appeared in some article on this disease lately and seemed indicated by the enormous amount of uric acid in the urine.

Khartoum.

TWO CASES OF ACUTE HÆMORRHAGIC PANCREATITIS.

BY H. W. WEBBER, M.D., M.S. LOND., F.R.C.S. EDIN.,
ASSISTANT SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

CASE 1.—A man, aged 61 years, was suddenly seized with acute abdominal pain on July 24th, 1904. He had appeared to be in his usual health the same morning and after breakfast had walked a distance of about a mile to church where he was a regular member of the choir. About 12 o'clock sudden violent epigastric pain attacked him; he was taken to his home and medical assistance was summoned. In the afternoon the pain continued with signs of collapse and some abdominal distension. Dr. A. B. Soltau saw him in consultation with Dr. M. L. Griffin and thought the symptoms pointed to a ruptured gastric or duodenal ulcer. At 11 P.M. (Mr. S. F. Lynch assisting) I opened the abdomen by a four-inch median epigastric incision and the cavity was found to contain clear blood-stained fluid but no gastric or duodenal contents. The stomach and duodenum were rapidly examined for perforation, none being found, and it was then discovered that the normal outline of the pancreas was replaced by a tumour composed principally of coagulated blood of the shape and size of a closed fist which bled immediately it was handled. The patient being in no condition to stand a search for the exact source of the bleeding a thick gauze plug was passed well into the hæmorrhagic mass and brought out through the parietal incision which was partly closed by mass sutures of salmon-gut. A hypodermic injection of morphine (a quarter of a grain) and strychnine ($\frac{1}{30}$th of a grain) was given. The patient never rallied and died about six hours after the completion of the operation. No post-mortem examination could be obtained.

CASE 2.—The patient was an American, aged 59 years, but looking at least ten years older. He was said to have worked very hard at business for several years. He landed at Plymouth on the evening of June 11th, 1905, apparently as well as usual, and at 10 P.M. had some strawberries and an apple. At about midnight violent abdominal pain seized him with vomiting, and this continuing at 3.30 A.M. Mr. H. H. Parsloe saw him and gave him a quarter of a grain of morphine hypodermically. This was repeated at 10.30 A.M. on June 12th. At 5 P.M. on that day he tried to get out of bed, pain returned with intense collapse, and he became cold, grey, and pulseless. With the injection of brandy and strychnine, the application of a mustard leaf to the præcordium, and hot bottles to the extremities, he partially recovered from his collapse and at 6.30 P.M. I saw him with Mr. Parsloe. He was then ashy grey in face with coldness of the whole body, except the parts kept warm by the hot bottles and friction. The pulse could just be felt at the wrist. The abdomen was soft; it was not at all distended; there was no dulness anywhere or local swelling; there was some tenderness on palpating the epigastric area. The rectum was empty. The patient did not recover from his collapsed condition and died about midnight (June 12th).

Necropsy.—At the post-mortem examination (on June 15th) there was no free fluid or gas on opening the peritoneal cavity. The gastro-hepatic omentum was distended with blood clot. The stomach presented a remarkable appearance, a subserous layer of clot covering the upper two-thirds of the anterior surface, leaving its lower third of the normal whitish colour. The gastro-colic omentum, transverse colon, and great omentum were normal, but on turning these upwards to examine the posterior surface of the stomach a considerable amount of clot was seen through the posterior layer of the transverse mesocolon. On tearing through this and raising the stomach the source of the hæmorrhage was found to be the pancreas which was represented by an irregular hæmorrhagic mass of clot and pieces of pancreatic tissue. The whole mass of stomach and clot, &c., was removed for further examination but circumstances causing this to be deferred for two days it was then found in an advanced state of decomposition.

The antecedent personal history in the second case threw very little light on the patient's condition. Some years previously a successful operation for radical cure of a right inguinal hernia had been performed and for some months before his last illness he had complained of breathlessness on exertion.

In the first case there was a definite history of an injury. Seven months previously the patient, while rising to leave his seat on the outside of an electric tramcar, was thrown by a sudden jerk of the car violently against the handrail, striking himself on the left side of the lower part of the chest and fracturing his seventh rib. From this accident he made a very slow recovery, it being more than three months before he was able to resume his occupation.

Plymouth.

RUSSIAN ODONTOLOGICAL CONGRESS.—On July 17th the Fourth Pan-Russian Odontological Congress opened in the Blagorodny Society's Hall, St. Petersburg. There is little of the business done at the congress that is reported further than that it was decided that in future the Odontological Congress should be held every two years and that the next should be held in Moscow in June, 1907. The sitting of July 19th had to be suspended owing to disorders through a difference as to allowing an unqualified person to give an address; but on the 20th, according to the *Sviet*, those who went to attend found a notice posted on the door of the meeting place saying that the congress was finally closed and that the excursion by steamer would not take place by order of the Governor-General of St. Petersburg, which order was supported by a detachment of police.

A Mirror
OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

LONDON HOSPITAL.

A CASE OF TORSION OF THE OVARY IN A HERNIAL SAC.

(Under the care of Mr. HUGH M. RIGBY.)

A FEMALE child, aged three months, was admitted into the London Hospital on March 17th, 1905. On the previous day the mother had noticed a swelling in the right groin which was tender and appeared to cause the child a good deal of pain. It had gradually increased in size and the skin had become inflamed over it. The child had not vomited and the bowels had acted as usual each day. The following condition was found on examination. A globular tense swelling extending up to the right external ring occupied the upper part of the right labium majus. It was elastic, appeared to be very tender, and the overlying skin was inflamed and slightly œdematous. The swelling stopped abruptly at the external ring but a narrow neck could be made out passing up into the abdominal cavity. The swelling was irreducible and an impulse could not be detected. The abdomen was not at all distended. The child was ill-nourished and undersized but did not appear to be acutely ill. The swelling was thought to be an inflamed encysted hydrocele in the canal of Nuck.

Shortly after admission to the hospital an operation was performed as follows. An incision made over the swelling revealed a sac containing dark fluid blood. When this was evacuated a dark purple body, smooth and oval in shape, presented. When this was freed from the sac wall with the finger the Fallopian tube, easily recognised by its fimbriæ, was seen. The purple structure was evidently the ovary, deeply congested, nearly black, and very much enlarged. A narrow neck was found at the internal ring composed of broad ligament and Fallopian tube acutely twisted on itself. The neck was untwisted, transfixed with a pedicle needle, and ligatured with catgut. The ovary and tube were then removed. The right horn of the uterus appeared at the internal ring, apparently tethered in this position by a structure which felt like a shortened round ligament. The skin incision was then closed and a drainage tube was inserted. Owing to the child's condition no attempt was made to dissect out the sac or to close the ring. The subsequent progress of the case was uneventful.

Remarks by Mr. RIGBY.—Similar cases have been recorded by Lockwood,[1] Owen,[2] Morgan,[3] and Schnitzler.[4] They agree with my case in that they presented almost identical clinical signs and symptoms. The hernia was on the right side in every case. All the children were quite young—namely, 11 weeks, six months, six months, and eight months respectively. In each a tender, inflamed, irreducible swelling was present in the groin and the contents of the sac as revealed by operation were identical.

Lockwood draws attention to the fact that the ovary lies in front of the tube, thus reversing the normal condition in the pelvis. Schnitzler lays emphasis on the fact that in these cases of twisted ovary in a hernial sac the symptoms of intestinal obstruction and peritoneal irritation are practically absent. In my case this was a noticeable feature, there was no vomiting and the abdominal signs of disease were *nil.* In Owen's case some vomiting had followed the appearance of the tumour but in all the other cases this phenomenon was absent. This is in striking contrast with cases in which torsion of an ovarian pedicle occurs within the abdominal cavity; in these vomiting and acute abdominal symptoms are the rule. The laxity of the broad ligament which forms the neck of the herniated ovary accounts for the ease with which a twist may occur, even to the extent of two or three times on its own axis. This is on a par with the excessively long mesorchium which is found in cases of torsion of the corresponding male organ. It is possible that a shortened round ligament associated with a patent canal of Nuck may play some rôle in the production of a hernia of the ovary on the same side. It probably accounts for the fixation of the fundus of the uterus in the neighbourhood of the corresponding internal ring. Le Dentu[5] considers that strangulation of a herniated ovary and tube is generally due to a band formed by the round ligament.

Reviews and Notices of Books.

Strength and Diet: A Practical Treatise with Special Regard to the Life of Nations. By the Hon. R. RUSSELL. London, New York, and Bombay: Longmans, Green, and Co. 1905. Pp. 649. Price 12*s.* 6*d.* net.

THE subject of national physique has attracted considerable attention recently and it is natural that the kindred question of diet should be brought into corresponding prominence. In medical publications many contributions to this subject have been made and we are glad to find a layman writing a book upon diet as affording a sign that general interest has been aroused on the national importance of food and drink in relation to health. It was therefore with considerable expectations that we opened the present volume and studied the author's views. We must frankly confess that we are disappointed in the substance of the book before us. The propositions which the author sets himself to prove are three in number: that under favourable conditions man can thrive on almost any kind of diet; that *ceteris paribus* vegetarian races are stronger and happier than nations living chiefly upon animal food; and that frugal persons and nations live better and longer than others and are more free from disorders of body and mind. The first and third of these will provoke little opposition in medical readers; the second is more controversial in character. When we examine the substance of the book which is intended to afford proof of these three propositions we find that it consists for the most part of a series of quotations from the works of other writers, and while admitting the modesty of the author who thus relies not upon his own observations or theories but on those of others, we must confess to finding the method as here exemplified unsatisfactory. The author shows most commendable impartiality in setting forth alike the opinions of those who are recognised authorities and of others who can hardly be included in such a category—of those who share his vegetarian views and of those who declare for the ordinary mixed diet affected by the majority of mankind. Little attempt is, however, made to coördinate the information given.

The book opens with an introduction which sets forth some evidence that civilised peoples are degenerating and includes incidentally a formidable list of ailments which "a medical man" has attributed to disorders of digestion; among them are included "consumption (alcoholic)"—apparently not meaning the consumption of alcohol—"bladder, kidney, and brain troubles; impure blood, nervous tremblings, &c.; cancer ...... coughs of many kinds ...... heart troubles of various kinds, hypochondria (*sic*), hysteria ...... lung troubles, neuralgia, noises in the ears, drunkard's paralysis, piles, rheumatism, sleeplessness, shingles, decayed teeth, dyspepsia, and uræmia." The list is as formidable as that of the maladies cured by any patent medicine but the author assures us that it falls short of the reality. Chapter I. deals with the proper diet of man as indicated by anatomical considerations and the author decides that our resemblance to the apes, which are frugivorous, proves that the proper diet of mankind is vegetarian. We doubt whether the argument is sound, since it would be easy to select, for example, two birds much more closely resembling one another than a man and an ape, yet one of which was carnivorous while the other lived only upon seeds and vegetable matter. The argument for vegetarianism derived from man's anatomical characters—teeth and intestines—is not very cogent. Nor is that derived from a consideration of the comparative longevity of different species of living creatures at all convincing, since the long life of the tortoise and of the elephant can be paralleled by that of the whale and of the crocodile. But we are anticipating the order of the chapters of the book before us. The second chapter is devoted to a discussion of the comparative values of foods, while the third deals with the food of different kinds of animals. Chapters IV. and V. are devoted to the diet of ancient and mediæval peoples, while Chapters VI. and VII. deal with the food of existing races and communities. Chapter VIII., headed Personal Experiences and Observations, does not, as might be expected, contain a summary of the author's own conclusions but a collection of dicta of distinguished and other persons on the matter of diet. Subsequent chapters deal with medical testimony on dietetics with stimulants and narcotics, with diet in relation to disease, notably cancer, and with its regulation in training for athletics.

On the whole we can agree with the author in many of his conclusions, notably in his views that most well-to-do people at the present day eat too much, especially too much meat; that many drink too much tea; and that stimulants and narcotics are not at all necessary for healthy persons. We cannot admit, however, that a reasonable amount of animal food is harmful, at all events for nations living in temperate climates; nor do we think that the somewhat vehement insistence upon the horrors of flesh-eating which we here find, even when enforced by the anecdote of the child who on returning from feeding a pet lamb was horrified at reading a recipe for the cooking of sheep's head, is quite adapted to convert thoughtful persons to vegetarianism. However, we must admit that in his account of the diets of different nations the author has brought together a large quantity of interesting information and that his earnestness and diligence are beyond praise.

Psychological Medicine: A Manual on Mental Diseases for Practitioners and Students. By MAURICE CRAIG, M.A., M.D. Cantab., M.R.C.P. Lond. London: J. and A. Churchill. 1905. Pp. 449. Price 12s. 6d. net.

THIS work is intended to meet the requirements of the general practitioner and the student. It is essentially practical, as becomes its character and aim. A few preliminary pages are given to normal psychology but the space at disposal is no doubt limited. A separate primer of psychology might better meet the needs of the student in this direction.

Under Classification of Insanity the schemes of various authors are given. It is held that the only satisfactory classification is one on a pathological basis and this our present knowledge does not permit of. The author employs a general scheme drawn up from various classifications—a good working scheme but an unsystematic one. We prefer the more logical scheme of Krafft-Ebing, which is based on the presence or otherwise of constant pathological lesions. A chapter on General Symptomatology deals with various elementary manifestations of perverted mental function and various disorders of bodily function (vascular, respiratory, trophic, and the like) therewith associated. As the reader's attention is directed to the importance of noting the shape and the size of the head it would, we think, have been as well to point out that the body, as a whole, may be profitably examined for evidence of defect and abnormality and to have referred to the subject of the signs of degeneration, briefly indicating its bearings on the study of the insane. Under States of Excitement it is taught that a necropsy on the body of a patient who has died from acute mania reveals no signs of organic disease. There are surely exceptions to this rule and in acute delirious mania there are frequently very marked hyperæmia and œdema, facts of which we find no mention in the paragraphs on morbid anatomy. Some might prefer to say that death in cases of acute mania, including acute delirium, is due to toxæmia rather than to "exhaustion resulting upon starvation" as is taught here, but our present ignorance of the pathogenesis of these conditions precludes definite statement and renders argument unprofitable. Amongst methods of treatment of acute mania the prolonged bath is very properly recommended. Unfortunately, the Commissioners in Lunacy, by declaring the method to be a form of restraint where a cover is used, have practically put an end to this excellent form of treatment.

The subject of dementia præcox is treated on the lines of Kraepelin's teaching but the author would prefer to reserve the designation for the hebephrenic form, considering that the catatonic and paranoidal forms are with difficulty distinguishable from catatonic stupor and paranoia occurring at other periods of life. Later, he states that the diagnosis between the paranoid form and paranoia "may appear somewhat difficult. Nevertheless, the diseases are very different when carefully studied." The first statement, pointing to a real difficulty so great that the author would rather not include the paranoid cases under dementia præcox, is hardly consistent with the second which indicates an apparent difficulty only. The wisdom of describing stupor and catatonia in one chapter and the kinds of dementia præcox, some of which are not distinguishable from them (and no attempt is made under "diagnosis" of the latter state to distinguish them) in another is very doubtful. The practical result of this would seem to be the description of the same condition twice over merely because it happens to occur at different periods of life. In passing we may be allowed to protest against the perpetuation of the term "anergic stupor," that fascinating redundancy which has cast a spell over many generations of alienists. Paranoia, secondary and "organic" dementia (the latter a common designation but open, we think, to criticism), and the epochal insanities are adequately treated on the usual lines.

Senile insanity is divided into "functional" and "organic" psychoses for reasons of convenience; we agree with the author that this is not a scientific classification. The distinction between partially curable and incurable cases can be drawn, if necessary, on clinical lines. The intoxication psychoses are well described; the important differential diagnosis between alcoholic pseudo-paralysis and general paralysis is very well summarised. The chapter on General Paralysis is good. We do not notice any reference to the subject of the examination of the cerebro-spinal fluid. It appears to be certain that lymphocytosis is always present in chronic meningitis and it is, according to certain authorities, one of the early indications of progressive paralysis, in which connexion the subject of cyto-diagnosis assumes considerable importance. The traumatic neuroses and neurasthenia are briefly considered and we think they rightly find a place in a treatise on mental disorder.

Under Epilepsy and Insanity it is stated that "all the work of the present time goes to corroborate the view that the epileptic convulsion is largely dependent upon some vaso-motor disturbance in the cerebral cortex." But experimental work (to some of which reference is made) as apart from speculation makes out, we think, a better case for the toxic basis of epilepsy. Under the heading of Treatment we think a reference to the method of eliminating chloride of sodium from the diet in conjunction with bromide treatment (Toulouse and Richet) would have been desirable. There is a useful chapter on Insanity and Physical Disease. Defective mental development is considered under the usual headings. Ireland's term, "genetous idiocy," is employed to designate a class. Surely the bulk of idiocy is "genetous" and the expression connotes nothing whereby a class is distinguishable. How can this expression adequately demarcate "a class of congenital idiot which does not rightly fall under any other division"? Discussing "moral insanity" the author gives classes of individuals in whom the moral sense may be affected; he thinks the term, if used at all, should apply to his class (*b*), "some children otherwise apparently normal." Why not also to class (*c*), "some men of genius"? Useful chapters follow on Feigned Insanity and the Relationship of Insanity with Law. Referring to medical certificates the author asks whether it is possible that the ready granting of such in doubtful cases of illness has led the lawyer to distrust in some instances the value of the evidence of medical men. In his gentle method of reproof the author displays a charming courtesy. Under Treatment we find a reference to the need for the prevention of the propagation of insanity. As regards "correction" of the insane (a term the author evidently prefers to "punishment"), it is represented that luxuries and pleasures can be stopped with benefit "apart from any desire to punish." The patient will probably judge from the action; for him there will not be much difference between correction and punishment. The book contains 22 excellent plates, mostly illustrative of the morbid histology of the cortex cerebri in mental disorders.

Notwithstanding that this work appears to lend itself in places to criticisms of the kind made above we believe that, as a whole, it is well adapted to the requirements of the class for which it is primarily intended. Avoiding, as far as possible, vagueness and theorising the book conveys practical information in a clear and an easy style and is characterised by good, sound sense.

New Methods of Treatment. By Dr. LAUMONIER. Translated and edited from the second revised and enlarged French edition by H. W. SYERS, M.A., M.D. Cantab., Physician to Out-patients, Great Northern Central Hospital. London: Constable and Co. 1904. Pp. 321. Price 3*s.* 6*d.* net.

THERE are three prefaces to this book—one by the translator; one by the author, dated October, 1902; and a third also by the author, or perhaps it would be more correct to say an extract from a preface to the second edition, dated October, 1903. In one of these there is a sad picture of the plight of the medical practitioner who has scant leisure to read and his patient "who is often better acquainted with the latest fashion in therapeutics than is frequently supposed." The author's aim has been to supply "definite and complete information" concerning the new drugs and methods of treatment the worth of which has been established and which are sufficiently well known to be described in a "definite and practical manner." The translator is not so sanguine about the permanent value of the observations contained in this book since he states that it must include an account of a considerable number of methods which in the near future will be more or less likely to be replaced and superseded by others.

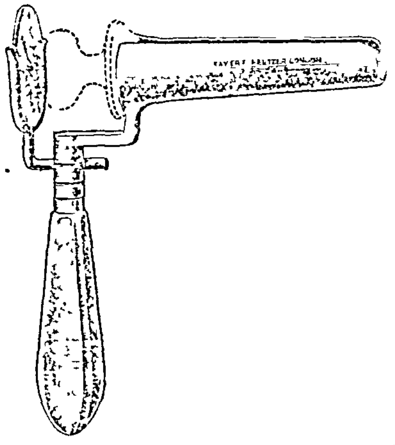
The subjects cover a wide range, including not only nutrition and blood alterants, respiratory, renal, and vaso-motor alterants, but also the curious group described under the heading of "Opotherapy." Sero-therapy, nerve alterants, antipyretics, and antiseptics are also dealt with. The different sections are very unequal. The section on the vaso-motor alterants seems unduly brief and that on opotherapy unduly long. With regard to the administration of opotherapeutic agents we are told that the method of ingestion by the mouth is by far the best (p. 197), but the enumeration of the different organs employed would act as a deterrent from general acceptation of this principle. There is much that is of interest concerning glycerophosphates, dionin, heroin, and some of the newer antipyretics, but many drugs of recent introduction are not included.

The translator states that he has endeavoured to bring the text into line with the English style and methods. French is so generally read with facility that the task appears to have been unnecessary. Many sentences in the English version are obscure and in the desire to ascertain the meaning the reader is under a constant temptation to try to translate back into French.

New Inventions.

NEW IMPROVED RECTAL SPECULUM WITH MAGNIFYING LENS ATTACHED.

ALL who have had much special practice in rectal surgery know too well how difficult it is in many cases to explore and to ascertain accurately the appearances *in situ* of growths, ulceration, &c., and to observe the normal and abnormal mucous surface of the rectum some inches up from the anal orifice. After careful exploration with the finger one would always like to have an ocular inspection of the cause of pain such as is produced by ulceration, hæmorrhage, abnormal growths, piles, or polypi in this region, and for such a purpose I have had an improved rectal speculum constructed which is easy of introduction with a split or space at the side and open at each end, provided with a wooden plug, and having at its lower end a convenient handle to hold it by. Attached to the outer opening of the speculum is a metallic half-circular rim for the purpose of receiving a powerful magnifying glass lens which can be moved in any direction but can at the same time, if necessary, be permanently fixed by screwing the handle up tight so as to grip the metallic bar which holds the lens. This speculum and lens I have been using for the last few months and it admirably carries out the object in view. It largely magnifies and thus enables the surgeon to see plainly the exact condition of the mucous surface of the lower rectum. I have to thank Messrs. Mayer and Meltzer, 71, Great Portland-street, London, W., for the satisfactory manner in which they have carried out my ideas in its construction.



The plate which illustrates this description accurately depicts the speculum in question. To throw light into the speculum when introduced into the rectum a small electric light can be used with great advantage.

LAMBERT H. ORMSBY, Knt., M.D.Dub., F.R.C.S.Irel.,
Ex-President of the Royal College of Surgeons in Ireland; Senior
Surgeon of Meath Hospital, Dublin.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT LEICESTER.

THE annual dinner was held in the County Assembly Rooms on July 27th when a large company sat down under the chairmanship of Mr. G. Cooper Franklin, the President. After the toast of "The King" had been duly honoured the toast of "The Imperial Forces" was proposed by the Bishop of Nottingham who remembered seeing the last wooden warship and the first ironclad. This was acknowledged by Fleet-Surgeon J. Lloyd Thomas and then followed Mr. M. O. Buzzard, K.C., who submitted the toast of "The British Medical Association." He asserted that the Association had done great service to the public as well as to the profession. After Dr. H. W. Langley Browne (chairman of the Council of the Association) had suitably responded, Dr. F. M. Pope proposed "The Mayor and Corporation of Leicester," to whom he said was due the success of the meeting. The Mayor of Leicester responded and paid a high tribute to the medical profession. The toast of "The President and Members of the Local Committee of the British Medical Association" was intrusted to Archdeacon Stocks, who discoursed on the marvellous progress of medicine and surgery and then discussed the virtues of the local committee. Mr. Franklin, the chairman, acknowledged the toast and then proceeded to give the toast of "The Guests," which was responded to by Professor Howard Kelly, whose speech met with a warm and enthusiastic reception. By this time the evening was far advanced and the subsequent proceedings were of an informal character.

Many of the members and their friends accepted the opportunity afforded to them of visiting the scene of some of Leicester's industries. The chief industries comprise the manufacture of boots and of hosiery, and Leicester also possesses more than one cigar factory. As an example of a boot factory the premises of the Coöperative Wholesale Society were visited and the various stages of the manufacture of boots were followed with interest.

The premises of Messrs. John Richardson and Co., Limited, manufacturing chemists, of Friar-lane, attracted very general interest, and quite large parties went through the various departments watching the processes concerned in the production of extracts, tinctures, tablets, pills, &c. The manufactory occupies a large site and the general arrangement of the departments was admirable, including a research laboratory, tincture rooms, percolation rooms, a pill mass factory, and so forth.

Those who travelled to Leicester by the Midland Railway route were impressed with the excellent service of that line and the ample accommodation afforded in the trains. In most of the trains a sumptuous and comfortable luncheon and dining car was included, in which an excellent, because simple, meal was served at a moderate price. The lavatory accommodation was also good. The fastest trains accomplished the journey, which is one of just upon 100 miles, in 105 minutes. The Great Central Railway has also a good service of trains and their route lies through the prettier country of the two.

The nineteenth summer general meeting of the Irish Medical Schools' and Graduates' Association, which we are informed now numbers 856 members, was held on July 26th at the Young Men's Christian Association building, Leicester. There was a very large attendance of members. In the absence of the President, Sir William Whitla (Belfast), who wrote to express his regret at being unable to be present, Mr. Alfred Freer, as the senior foundation member present, was voted to the chair. The chairman called on the Provincial Honorary Secretary to address the meeting in reference to the question of the monopoly of honorary hospital appointments in England. The Provincial Honorary Secretary then detailed the efforts that had been made—in four cases successfully—to have the exclusive rule repealed which restricted these appointments to those holding the diplomas of two particular colleges. He said that there was prominent in the English character the love of justice and that when the governors of any institution in which the restrictive rule existed had it brought home to them how unfair it was (now that all territorial distinctions were abolished by law between the three kingdoms as regards medical qualifications) to put obstacles in the way of those holding such high qualifications as the Fellowship of the Royal College of Surgeons in Ireland and the Membership of the Royal College of Physicians of Ireland they gladly carried out the principle of the "open door" and repealed the obnoxious rule. But the difficulty was the expense of bringing the facts of the case under their notice. He was glad, however, to say that with the prospect before them of a large accession of new members the Council had determined to enter soon upon another assault on a monopoly fortress and he was sanguine of the same success as had attended similar efforts at Bristol, Hastings, Brighton, and elsewhere. The proceedings concluded with a vote of thanks to the chairman, who said he was old enough to remember the instructions which he received in Dublin 50 years ago from the teachers in what still was recognised as the best practical school of obstetrics in the United Kingdom, if not in the world.

The annual luncheon of the Continental Anglo-American Medical Society took place at Leicester on July 27th. Professor Osler presided and was supported by the following members of the society: Dr. StClair Thomson, Dr. H. E. Leigh Canney, Dr. W. Page May, Dr. H. O. Hobson, Sir Michael Foster, Dr. D. E. Anderson, Dr. M. W. Gairdner, and Dr. F. M. Sandwith. Amongst the guests were Professor R. W. Boyce (Liverpool), Dr. W. J. Tyson (Folkestone), Dr. W. Ewart (London), Dr. P. Watson Williams (Clifton), Professor A. R. Cushny, Dr. Bertram L. Abrahams (London), Dr. A. J. Chalmers (Colombo), Dr. Camac (New York), and Dr. G. Wells (Chicago). There were no formal speeches but Dr. Sandwith reminded the members that the next meeting of the society will take place in Paris in October during the Congress on Tuberculosis when it is hoped that there may be an unusually large gathering. Dr. Ewart, on behalf of the guests, returned thanks to the society for the hospitality shown to them.

The number of members of the British Medical Association attending the annual meeting who play golf has of late been gradually increasing and this year they were especially fortunate in the enjoyment of the hospitality of the Leicestershire Golf Club. On July 28th a match was arranged between England and Scotland, Wales, Ireland, and the Colonies in which the victory rested with the representatives of England. Before the match a very enjoyable lunch at the golf-house was partaken of by the players. A vote of thanks to the Leicestershire Golf Club for its great hospitality was proposed by Dr. J. Playfair, President of the Royal College of Physicians of Edinburgh, and cordially seconded by Dr. F. M. Pope. The President of the Leicestershire Golf Club, Mr. B. W. Russell, duly acknowledged this compliment and then the match commenced. The result was as follows:—

We publish the following story which one of our representatives on his way to the sections heard at a labour meeting in the Market-square at Leicester, not at the British Medical Association, firstly, because it has a medical flavour and, secondly, because it shows that the working-classes are quite alive to the manner in which they may be cheated. There was a man in ——— who kept a small draper's shop and who had an assistant who was new to the business. One day an old lady came in and asked for some silk. The youthful assistant showed her some, saying, "We can do this for you at 6*s.* 6*d.* a yard." The old lady asked for something better but the assistant replied that they had nothing better. Whereupon the master came forward and said to the assistant, "I'm surprised at you showing this lady stuff of that quality, take it away and put it back on its shelf." Then, turning to the customer, he said, "You must excuse my assistant, madam, he is new to the business but if you will allow me I will show you something very superior." He went away and returned bringing the same piece of silk. "This, madam," he said, "is a very superior article, 10*s.* 6*d.* a yard. If it were not for the fact that I bought it some time ago we should have to charge you 15*s.*, for, as you are doubtless aware, owing to the recent epidemic among the silkworms the price of silk has increased enormously of late." The customer took the silk, paid for it, and went away. The draper thereupon lectured his assistant, saying, "You'll never make a man of business, you've no commercial adaptability; mark my words and remember what I said for the next time." A few days later the draper was having his dinner, leaving his assistant at the counter. Hearing a noise he looked out and saw the same old lady belabouring his assistant with her umbrella. He separated them and asked the assistant what he had been doing. "Oh," said the assistant, "I was merely carrying out your instructions. She asked for some tape and I showed her some. I said, we can let you have this at 8*d.* the dozen yards. If it wasn't for the fact that we have had it in stock some time we should have to charge 1*s.*, for, as you are doubtless aware, owing to the recent epidemic among the tapeworms, the price of tape has gone up enormously of late. Then she hit me with her umbrella."

THE SECTIONS.

MEDICINE.

THURSDAY, JULY 27TH.

Dr. HOWARD H. TOOTH (London) opened a discussion on

The Pathology, Diagnosis, and Treatment of Various Forms of Acute Meningitis.

He said that during the last year 45 cases of meningitis of various forms had been under observation at St. Bartholomew's Hospital. They were tabulated as follows:—

Variety.	Recovered.		Died.		Total.	
	M.	F.	M.	F.	M.	F.
Tuberculous	0	0	13	9	13	9
Posterior basic	4	2	5	0	9	2
Pneumococcic	0	0	0	2	0	2
Streptococcic	0	0	3	0	3	0
Purulent (undetermined)	1	0	3	3	4	3

Such factors as might be considered of importance in differential diagnosis were briefly considered and among others the following: 1. Earliest symptoms of onset. 2. Duration. 3. Mental symptoms. 4. Eyes: optic neuritis, common in tubercle, less so in other forms; earliest appearance of optic neuritis. 5. Squint: mostly internal; very common; often transitory; almost invariable in the posterior basic form. 6. Other forms of paralysis. 7. Tonic muscular spasm; retraction of the head; opisthotonos; rigidity of limbs (Kernig's sign), almost invariable in posterior basic, less so in other forms; cerebellar irritation, its probable cause; hypertonicity of cerebral origin (for example, in spastic diplegia) contrasted with cerebellar; the variability of reflexes in cerebellar. 8. Fever: general remarks on types; the relation of the pulse and respiration to fever; tendency to progressive acceleration of the pulse and respiration, irrespectively of the temperature. 9. Lumbar puncture. The prognosis was most favourable in posterior basic cases as a whole. Out of 11 cases six recovered. The chances of recovery seemed to be greater the older the patient. Tuberculous and pneumococcic cases were invariably fatal. The mortality would appear to depend on the generalisation of the inflammatory process, this tendency being least marked in posterior basic cases.

Dr. T. J. HORDER (London), in dealing with the pathological aspect of the subject, insisted on lumbar puncture as of prime importance in determining the nature of the organisms which could be directly demonstrated or inferred from the chemical and histological characters of the fluid. The needle employed should be three and a half inches long in the case of adults and two and a half inches in that of children. A line across the iliac crests traversed the fourth lumbar vertebra and the puncture might be made either above or below in the third or fourth interlaminar space, the needle being directed from a point half an inch to one side of the middle line forwards, inwards, and upwards. The cerebro-spinal fluid should flow spontaneously without the aid of suction whether disease was present or not. When clear and free from albumin or cells it might be considered healthy. Albumin and cells were present with meningitis and in greater quantity when pyogenic organisms were present, polymorphonuclear cells being especially plentiful (90 per cent.), whereas in tuberculous and meningococcic cases scanty and small lymphocytes were found. The meningococcus was most often found but was sparsely distributed. For cultures a blood agar medium proved the most satisfactory, but in 15 tuberculous cases these proved sterile. In two cases rapid improvement appeared to follow puncture. The blood examination demonstrated a high leucocytosis in meningococcic infection, a medium one in tuberculous, and the smallest in streptococcic, owing probably to the intense intoxication. In pneumococcic and meningococcic disease the blood stream was infected so that there was some general septicæmia, and in cases showing pneumococci and meningococci with nasal and aural discharge these organisms were demonstrable in them. 50 per cent. of the tuberculous cases were generalised from glands in children and from the joints, bones, or lungs in adults. The distribution of the organisms in meningococcic infection was hæmophilic (intracellular). Injection of cultures in animals induced virulent blood infection but not the characteristic lesions. Pneumococcic infection was either pure or mixed with others. The surgical cases involving the ear and nose were mostly streptococcic. Local mixed infection appeared less common than was ordinarily stated and was usually secondary to old ear disease, but mixed infections of the blood and general system were common. Post-mortem examination showed pia-arachnoid disease, but in middle-ear suppuration the subdural space was principally affected. Suppuration occurred most rapidly with pneumococci, rather less so with streptococci, and though fatal meningococcic cases proved purulent this was probably not the case in life and in those which recovered. Tuberculous effusion occurred principally at the base of the brain and in the Sylvian fissures but there was some variation. The pneumococcus and meningococcus produced effusion in the posterior basic region. All cases of acute meningitis were cerebro-spinal.

Professor W. Osler (Oxford), referring to epidemics of cerebro-spinal meningitis, said that the disease was limited to certain districts or cities; it never became pandemic. During the past six to eight months cases had occurred in some numbers in New York and in Silesia after an interval of 30 years. A few cases occurred also in Ireland. Sporadic cases followed on epidemic. Posterior basic or cerebro-spinal meningitis must be regarded as one of the most fatal diseases of early life, although from 30 to 50 per cent. of the sporadic cases recovered. Pneumococcic and meningococcic forms were easily mistaken for one another. The germs presented but slight vitality outside the body. They occurred in the buccal and pharyngeal secretion and had been isolated in 9 per cent. of healthy men in the nasal mucus. Entry was probably effected through the sphenoidal cells rather than by the ethmoidal foramina. Contagiousness was illustrated by the conveyance of the disease with fatal effect to medical attendants and nurses and resembled that of pneumonia; it was also shown by a series of rapidly fatal cases in a house epidemic. In one series of 93 cases of meningitis investigated 35 proved to be tuberculous and 32 meningococcic. Meningococcic meningitis was characterised by the occurrence of purpura and sometimes arthritis. The spinal sometimes overshadowed the cerebral symptoms and in all cases the specific coccus could be identified by lumbar puncture. Recovery was limited to this form of leptomeningitis, 17 of the above-quoted 32 cases getting completely well, though in one case sight was lost. On the other hand, the 21 pneumococcic cases, all the tuberculous and the mixed infections of tubercle and streptococci, as well as the pure streptococcic ones, died. Lumbar puncture should be repeated when the tension of the cerebro-spinal fluid was high (300 millimetres). As in pyæmia the meningococcus might invade the circulation, occurring in the joints. The exudate on the meninges cleared off, as had been observed in one case which had been exposed in operation and which died some months later from paraplegia.

Dr. H. Montague Murray (London), referring to the duration of cases, said that those in which the onset was definite lasted about one month, while others with indefinite onset were protracted to three months.

Dr. F. M. Pope (Leicester), the President of the Section, made some remarks on cases of pneumococcic cerebro-spinal meningitis. He also referred to a case of pachymeningitis hæmorrhagica in a child exhibiting signs of intracranial pressure whose cranium was opened, allowing escape of fluid from the subdural space, but who subsequently died.

Dr. C. N. B. Camack (Cornell University) spoke of the value of examination of the nasal secretion and of the various micro-organisms which had been identified, including the micrococcus catarrhalis and the influenza bacillus.

Dr. S. West (London) described the curious periodicity of respiration in meningitis: (1) Cheyne-Stokes form with intervals of 40 seconds of apnœa and then periods in which the respirations attained a maximum of 120 per minute, the general average being maintained; and (2) grouped respiration with pauses of ten seconds, slow and equal, so that the total only amounted to from eight to ten per minute. Recovery sometimes occurred in the latter form, never in the former.

Dr. StClair Thomson (London) said that suppuration occurred in the accessory cavities of the nose as frequently as in the middle ear of the child and called for the more systematic investigation of the nasal cavities in post-mortem examination. He referred to cases of cerebro-spinal rhinorrhœa and of sinusitis which proved fatal.

Dr. W. B. Warrington (Liverpool) described some points in staining the organisms and referred to a case in which the finding of pus by lumbar puncture had contra-indicated operation for abscess in connexion with the ear.

Dr. T. F. S. Caverhill referred to a recent outbreak of cerebro-spinal meningitis in which fatal cases had been returned as pneumonia, in one case a boy who had gone to bed well being found dead next morning.

Dr. Tooth, in reply, said that pneumococcic meningitis accounted for some very rapidly fatal cases. He also suggested that many epileptic cases might be the sequels of recovery from cerebro-spinal meningitis.

Dr. Nathan Raw (Liverpool) read an interesting paper entitled

Human and Bovine Tuberculosis, with Special Reference to Bovine Infection in Children,

in which, while confirming the German view of the difference between the two micro-organisms, he insisted upon the danger of bovine tuberculosis to human beings in that they were liable to contract tuberculosis in either form, though the distribution and course of the disease might be diverse. Bovine tuberculosis affected young people, was traceable to infected milk, and affected the tonsils, the alimentary tract, the glands, and, through the blood, the meninges, the bones, the joints, and other parts, while human tuberculosis was air-borne and affected adults by way of the lungs as pulmonary phthisis. In evidence of this Dr. Raw indicated the rarity of pulmonary phthisis in infants and children and, on the other hand, the comparative rarity of other than pulmonary lesions in adults, and suggested, further, that early tuberculous disease, presumably bovine, appeared to be protective against phthisis, as the development of pulmonary tubercle was relatively rare in those of a strumous diathesis who had suffered in infancy from bone and gland lesions. It might be, similarly, that cattle would be protected against bovine tuberculosis by the attenuated virus of the human form. Dr. Raw stated that it was not uncommon to find from 20 to 25 per cent. of cattle in various herds suffering from tubercle, though in only about 2 per cent. were the udders affected; but even then there would be a plentiful supply of bacilli in the mixed milk. This matter was of great importance in the inspection of cattle and dairies and also in connexion with imported milk products, as the disease was more prevalent in some countries, such as Denmark, than in England. In an investigation of 400 cases of tuberculosis in infants in only two cases could the possibility of infection be traced to the mothers, all the others having been fed on cow's milk.

Dr. R. Pratt (Leicester) said that the source of tuberculous infection was easily discoverable in cattle, as pus and blood were removed from the tuberculous udders with the milk. In an investigation into the dust of certain tenements it was found that the material obtained from the houses in which tuberculous persons lived contained the bacilli while that of the dwellings of healthy people did not. In the process of separating and sterilising milk the amount of dirt and foreign matters, including mucus and such things as had been already mentioned, was astounding.

Dr. F. H. Jacob (Nottingham) reported the discovery of tubercle bacilli in milk microscopically.

Sir William Broadbent (London) emphasised the importance of the statements made, which meant that they must accept two distinct varieties of tubercle.

Dr. West said that there were rare cases in which pulmonary tuberculosis resulted from direct extension from caseous glands. The stress of the disease evidently fell on different tissues at different ages. Whatever view was held they were driven back to the origin of tuberculosis in milk and their first duty was the rectification of the milk question.

Dr. F. J. Poynton (London) read a paper upon

The Employment of Citrate of Sodium in the Feeding of the Infant.

Two years' experience of the method had confirmed him in the opinion of its value which was indicated in a paper published in The Lancet of August 13th, 1904. The principle of the method consisted in adding citrate of sodium to cow's milk and thus altering the clot. The acid caseinogen combined with the sodium of the sodium citrate to form a casein curd which was of lower molecular weight than when calcium was the base, and hence the curd was finer and looser. The calcium, on the other hand, combined with citric acid to form calcium citrate which, much diluted by the stomach contents, was absorbed into the system and was not lost to the economy. The changes in the curd were illustrated by a series of tubes and Dr. Poynton insisted that this method was quite different in effect from the well-known device of adding sodium bicarbonate, which, as he demonstrated, hardly altered the consistence of the clot. This method was serviceable (1) in weaning the healthy infant; (2) for enabling the child to take cow's milk in a more concentrated form; and (3) for correcting milk dyspepsia. It was cheap and did not introduce the danger of scurvy. On the other hand, it was not a powerful remedy in the sense of being antibacterial or antitoxic, nor would it be effectual in dyspepsia from excess of fat. A very useful routine proportion was one grain of citrate of sodium to the ounce of milk. This could be increased if necessary to two or three grains to the ounce.

Dr. H. W. GARDNER (Shrewsbury) spoke in confirmation of the value of this method of treating milk both in adult invalids and in infants.

SURGERY.

THURSDAY, JULY 27TH.

The meeting of the section commenced with a discussion on

The Treatment of Malignant Disease of the Rectum,

which was opened by Sir CHARLES B. BALL (Dublin), the President of the section. He first showed a series of lantern slides which illustrated chiefly the anatomy of the rectum, but some showed the varieties of new growth. He pointed out that the published statistics of radical operations for the removal of malignant disease varied considerably, both as regards the immediate mortality of the operation and the question of recurrence. The subject had been previously discussed at an annual meeting of the Association but it was thought that the time had come when it might be useful to review the large amount of work already accomplished, to endeavour to estimate the real progress that had been made, and to define the scope of the various operations for extirpation of carcinoma of the rectum. No sensational innovations were to be looked for at present but they could study with a judicial mind which methods should be accepted as standards until the time came to which all looked forward with confidence when the cause of cancer should be discovered and they should learn how its cure might be effected, perhaps by a hypodermic injection or some rays. Of recent years the results had been more encouraging and this might be due to many causes, such as early diagnosis, the better selection of cases, greater attention to the preparation of the patient, and improved methods of operation. An early diagnosis was of the first importance, for only too often were cases seen in which slight diarrhœa had gone on for months or a considerable loss of blood at stool had been attributed to piles when a simple rectal examination would have revealed a cancerous mass which, left undetected, became incapable of removal. The importance of these slight symptoms was now more widely recognised and therefore many more cases were seen at an early stage of the disease. Digital examination was, as a rule, simple, as the ordinary form of adenocarcinoma generally lay within reach of the finger. The operation of radical extirpation of malignant disease of the rectum had been much discredited by operations on cases which were far too advanced, for in these the immediate risk was great and if the patient should survive the operation recurrence was almost certain to follow. Statistics, as in so many other cases, were most misleading in carcinoma of the rectum but it was certain that if the columnar-celled carcinoma of the rectum was operated on early, before the tissues surrounding the rectum were much involved, the results were admirable, both as to the immediate recovery and as to freedom from recurrence. In his own practice there had been several cases of undoubted columnar-celled carcinoma which had survived the operation for from 10 to 15 years without any recurrence. In selecting a case for operation attention should first of all be paid to any evidence suggesting the presence of secondary infection either in the liver or the deep lymphatic glands of the abdomen. Then the mobility of the malignant mass should be examined and if found to be freely moveable the case was suitable; but every increase in the degree of fixation increased the dangers and difficulties of the operation and the probability of recurrence. The preliminary preparation of the patient was of great importance. The patient should be fed with food likely to leave but little residue and the bowels should be freely opened with purgatives for four or five days before the operation, and on the day preceding the operation a copious enema should be given to empty the colon completely, while on the night before the operation an opiate would check the peristalsis. The rectum should again be washed out two hours before and immediately preceding the operation with a 2 per cent. solution of creolin. In this way it was possible to diminish largely the risk of infection of the wound. If it were not possible to effect this through evacuation of the colon on account of the tightness of the stricture a previous colotomy was clearly indicated but in most cases this would be unnecessary, and, indeed, objectionable, as it caused delay and subjected the patient to a double operation. As to the method of operation, the perineal route was probably still the best if the disease involved only the anal canal and especially if the whole circumference of the canal was not affected. In all other cases the choice lay between the sacral route and the abdominal. After the removal of a malignant growth of the rectum by the perineal route incontinence of fæces was very likely to occur if the growth involved the anal canal. Sepsis was very common after wounds which opened up the rectal wall above the pelvic diaphragm, because blood and serum were liable to become widely diffused and became suitable media for the growth of bacteria. It was therefore very necessary to close the deeper portions of the wound by deep sutures or to make due provision for drainage. Sometimes it was possible to prolapse the entire disease through the anus and in such a case excision could be easily carried out, and the wound having been sutured the bowel could be returned within the anus. For the sacral route Sir Charles Ball preferred the following modification of Kraske's operation. The skin having been cleansed an incision was made from the middle of the sacrum to within an inch of the anus; then with an American pruning shears the ligaments were separated from each side of the coccyx; a cut was then made through the fifth sacral vertebra and the triangle of bone was removed. The rectum being then exposed the peritoneum was opened early on both sides and a loop of bowel drawn out. The rectum was ligatured above the growth and then below, the malignant mass being removed. Sometimes it was necessary to make a sacral anus, as when it was impossible to free the upper segment sufficiently to bring it down. Exceptionally it might be possible to unite the cut edges after resection and if successful a very perfect result was obtained, but usually the stitches gave way under the strain of the passage of fæces. It was better to suture only the front and sides of the bowel, leaving the hinder portion open, a later plastic operation closing this opening. For most cases, however, Moulonguet's operation was best. He dissected out the lower portion of bowel to the upper surface of the pelvic diaphragm and the entire mucous membrane down to its junction with the anal canal, the sphincter being carefully preserved. The upper end of the bowel was then freed sufficiently to bring it out at the anus without tension, where it was then sutured. In three cases Sir Charles Ball had, in removing a carcinoma of the rectum, excised also a portion of the posterior wall of the vagina to which the growth was attached but rapid recurrence occurred in all. The abdominal route had probably not yet assumed the position in surgery to which it would ultimately attain. By the abdominal incision it was possible to estimate the extent of the disease and the amount of lymphatic involvement, so that if the disease were too extensive a colotomy might be performed. By the abdominal route also it was easier to control the hæmorrhage and there was also little risk of causing peritonitis. Many cases which had been treated by the trans-sacral route would have been better treated by the abdominal method. It was not necessary to terminate the abdominal method by a permanent colotomy but in many cases it was possible to bring down the divided colon to the anus and fix it there with perfect sphincteric control. It was well in this operation to have the patient in a very elevated Trendelenburg position so as to leave plenty of room in the pelvis. The abdomen was opened by an incision separating the fibres of the left rectus muscle. A loop of pelvic colon was drawn out and the point where the mesocolon was longest was determined; the colon was then ligatured and divided and the lower portion of the mesocolon was divided bit by bit and tied, and then by blunt dissection the bowel could be cleared down to the pelvic diaphragm and tied and divided. The upper portion was then brought out at the anus and fixed there.

Professor HARTMANN (Paris) said that since 1896 he had treated 64 cases of malignant disease of the rectum. In 43 palliative treatment only was possible and in these he had performed an inguinal colostomy and in this operation he brought up the peritoneum to the skin and fixed the colon but did not open it. Two days later he made a small opening into it with the actual cautery. Of these colostomy cases one died. In 21 cases he had found it possible to excise the growth of the rectum. When it was possible to remove the growth through the anus it was necessary to bring the bowel down and preserve the anus. If this was impossible the best method was to establish a sacral anus. He never performed a preliminary colotomy. In one case a patient was alive now, more than five years since the excision of the malignant growth, and there were many others which had survived for shorter periods without any signs of recurrence. Of the 21 cases only one died. The most important point in treatment was early diagnosis.

Mr. F. Swinford Edwards (London) considered excision of malignant disease of the rectum to be a satisfactory operation if the surgeon could be certain of removing the whole disease. The site of the affection made little difference but early diagnosis was essential. If by digital examination the growth could not be detected the proctoscope should be employed and Strauss's instrument was probably the best. The mobility of the growth could only satisfactorily be determined under an anæsthetic. His cases which were of long enough duration to be considered were 40 in number and of these three died, a mortality of 7·5 per cent. In one case ten years had elapsed without any sign of recurrence; but, on the other hand, in one case recurrence had occurred after eight years, if indeed it could be called a recurrence. According to his experience villous tumours often became carcinomatous. In Kraske's operation he was in favour of direct end-to-end suturing of the divided bowel and even though a temporary fistula formed the ultimate result was good. There were three points on which he laid stress: (1) If the peritoneal cavity had to be opened a preliminary colotomy was very advisable; (2) he endeavoured to avoid opening the peritoneal cavity when possible, as thus the risk of the operation was materially lessened; and (3) he doubted if it were ever advisable to remove only a portion of the circumference of the bowel even if only one part should be involved, because of the very great tendency possessed by malignant growths of the rectum to spread round the bowel.

Mr. F. C. Wallis (London) said that the advisability of attempting the removal of a carcinoma of the rectum depended on its situation, its fixation, and the general condition of the patient. When the trans-sacral route was advisable he employed a division of the bone in the shape of an inverted V in place of a transverse division as it gave more room. When necessary a temporary sacral anus might be established, a subsequent plastic operation closing it. Sepsis in rectal operations was avoided with great difficulty and therefore the utmost should be done to sterilise the contents of the bowel. Mr. Wallis showed some lantern slides illustrating his remarks.

Mr. Sinclair White (Sheffield) described and showed the specimen of a case of growth of the rectum in which a little tube looking like a vermiform appendix was present. In his opinion it was a persistence of the neurenteric canal. With regard to the operative treatment of malignant disease of the rectum his experience in the main confirmed the statements of previous speakers. He had had 26 cases of Kraske's operation with nine deaths and of the cases recovering from the operation only four had passed the three years' limit without recurrence, and of these two had strictures and one had a fistula. In his later cases of Kraske's operation he had been in the habit of splitting up the rectum from the anus into the sacral wound and dissecting out the disease. Except in very early cases he always performed a preliminary colotomy and amongst other advantages it enabled the surgeon to examine the disease from above.

Mr. A. B. Mitchell (Belfast) suggested that it might be advisable to begin the operation of excision of a malignant growth of the rectum by Kraske's method by dissecting up the mucous membrane and ligaturing it in order to avoid infecting the posterior wound. The value of the abdominal route was hardly proved but he had recently seen described an operation by a lady surgeon which seemed to promise well.

Mr. T. G. Atkins (Cork) expressed the hope that medical men would diagnose more early than hitherto cases of malignant disease of the rectum by paying attention to slight symptoms, such as mucous diarrhœa. A rectal examination should be made and the Trendelenburg position and deep anæsthesia were of the greatest value in diagnosis, as was also Strauss's aeroproctoscope. The possibility of removing a malignant growth of the rectum depended on its mobility, the absence of extensive disease of the lymphatic glands, a fair general condition, and the absence of metastases. The operation should be as aseptic as possible. When the sacral route was employed the bone should not be divided at too high a level, for the abdominal route was more suitable for any growths which were not easily accessible through the sacral incision.

Mr. J. Lynn Thomas (Cardiff) pointed out the very great discomfort and worry caused by the presence of an artificial anus. He showed a specimen of a large malignant growth of the rectum which he had excised by the abdomino-perineal route.

Mr. E. Stanmore Bishop (Manchester) had had 35 cases in which he had excised malignant growths of the rectum. He thought that it was necessary to consider together malignant growths of the rectum and the sigmoid flexure. In many cases he held that it was not possible at first to decide as to the malignancy of a rectal tumour. The symptoms were often untrustworthy, but in his opinion the symptom of most value was some definite alteration in defæcation. He was strongly in favour of a preliminary colotomy. He always employed Kraske's operation or the abdominal method. The preliminary colotomy was of great value in removing dilatation of the bowel and the muco-colitis which was generally present.

Mr. E. Deanesly (Wolverhampton) expressed the opinion that in any patient it was perfectly possible to remove the whole rectum. One important contra-indication was the involvement of the bladder or ureters. He did not share the dislike for a palliative colostomy expressed by a previous speaker, for if the fibres of the abdominal muscles were separated and not divided they would form a sphincter. Moreover, a large enema every morning would make the patient comfortable for the day. In inoperable cases curettage was very useful; it removed the discharge and pain and it might be repeated several times. He had discarded the perineal route. In the sacral operation he preferred the prone kneeling position. He had employed the abdomino-perineal route in one case which did well but he preferred the trans-sacral route.

Mr. C. Ryall (London) always examined these cases under an anæsthetic as it was otherwise impossible to estimate the suitability of the case for operation. If there was any doubt he always gave the patient the chance. He did not consider a preliminary colotomy necessary and it was undesirable, for the trans-sacral operation was serious and a preliminary colotomy undermined the patient's strength. He regarded all malignant growths as infective and therefore took the greatest care to prevent the growth being torn or cut, and he thought it of great importance to obtain early healing as thereby the chance of infection was lessened. The deeper parts of the wound should be firmly closed so as to leave no cavities. The sooner in the operation the peritoneal cavity was opened the better, as the surgeon knew where he was.

Mr. J. Jackson Clarke (London) pointed out that there were some cases of ulcerative colitis which simulated high rectal carcinoma. He was in favour of an exploratory incision near the middle line of the abdomen, by which much could be learned and, if necessary, a colostomy could be performed. He was inclined to think that in the future the sacral route would become rare.

The President of the section, in closing the discussion, congratulated Professor Hartmann on his very successful series of cases of extirpation of rectal carcinoma. In reference to Mr. Sinclair White's specimen he said that he was inclined to attribute the little tube-like body to a persistence of the post-anal gut. He agreed with several of the speakers that the abdominal route would become more common. He referred also to a case of his own where he performed inguinal colotomy for inoperable rectal carcinoma, but two years later there was no sign of any disease in the rectum and he was able to close the colotomy opening. He said he might mention that no serum of any kind or even violets had been employed in the case.

Mr. Sinclair White read a paper on

Gastro pyloro-duodenostomy.

This operation is that which was referred to at Wednesday's meeting as "Finney's operation" and Mr. White described the operation and illustrated it with some diagrams. He considered the operation to be of great value as the opening could not contract. He thought it worthy of a prolonged trial.

Mr. C. P. Childe (Southsea) read a paper entitled

An Unusual Condition of the Large Intestine associated with Carcinoma in Two Sisters, together with Carcinoma of the Rectum in a Third Sister.

The first patient was 35 years old and for nine years had had rectal symptoms, mucous discharge and tenesmus.

There was a large carcinomatous ulcer in the rectum with many polypoid growth [illegible] were removed by Kraske's [illegible] Numerous other polypi were present higher up the bowel. The second sister was 32 years of age and was admitted into the hospital at the same time. For four years she had had a rectal discharge of blood and mucus. Here also was a malignant ulcer of the rectum with multiple papillomata. This patient refused operation. The third sister was 34 years of age and had had no symptoms till she saw her sisters in the hospital. She then complained of pain in the back and when examined was found to have a large mass on the anterior wall of the rectum but no polypi. The father had died from some rectal trouble. The first two sisters had occupied the same bedroom, and often the same bed, for ten years but they had never used the same enema syringe. The third sister had often visited them for a week at a time and had slept with each of them, though she had lived in London. Harrison Cripps had mentioned three cases in one family with multiple papillomata of the rectum. Further, out of 14 cases of multiple papillomata of the rectum recorded three had ended in carcinoma. The cases he had described suggested an infection.

The PRESIDENT of the section said that he considered these multiple papillomata to be very similar to the ordinary warts on the hands which were well known to be infectious.

Mr. L. A. BIDWELL (London) read a paper on a case of

Cystic Tumour of the Omentum.

The patient was 62 years of age and grew steadily thin and weak. Ascites was present and he was tapped and four gallons of blood stained fluid were removed. A mass was felt below the liver and was thought to be malignant. He was tapped at intervals and at last it was thought advisable to explore the abdomen and the tumour was then removed. It was found to arise from the omentum and consisted of round and spindle cells. The patient was well eight months later.

STATE MEDICINE.

THURSDAY, JULY 27TH.

Dr. L. A. WEATHERLY (Bath) introduced a discussion on

Sanatoriums for the Poorer Consumptives.

He stated that he believed in the value of sanatoriums, for they had undoubtedly done good, even if high-flown expectations had not been fully realised. He would discuss the subject chiefly under the heading, Were such sanatoriums necessary and, if so, how were they best started and maintained? He believed they were necessary; no other treatment had been so efficacious in *arresting*, he would not say *curing*, the disease; no other means so effectually provided good air and a full diet and nothing was so useful for the purpose of teaching the tuberculous patient how to live. Tinkering of cases in backyards, with home worry and poor food, only brought discredit upon the treatment. He thought that sanatoriums for the poorer classes might be of three grades. First, those which should be provided by the boards of guardians for the poorest. These might either be special buildings erected for the purpose or special wards allocated at the Poor-law infirmary. The guardians had the power in their hands and should use it. It was proper and it was economical. Out of 769 boards he had found that only 18 per cent. were doing anything for their consumptives. The next class of poor were those who could not afford to pay the usual sanatorium fees and to provide for those help must be obtained from county and district councils, from the working classes themselves, from manufacturers, and from the philanthropic public. Thirdly, there should be sanatoriums for those who could pay from 25*s* to £2 weekly. He knew from actual experience that a sanatorium of 60 beds would pay its expenses at 25*s.* per week from each patient. Any profit which might arise from such sanatoriums should go to help Class No. 2. The difficulties at present in the way of effective treatment of the poorer consumptives were chiefly that the sanatoriums were hopelessly too few, that early diagnosis was neglected, and that patients were even now averse very often to take the advantage of sanatorium treatment.

Dr. PHILIP BOOBBYER (Nottingham), the President of the section, observed that there was no doubt necessity for sanatoriums for the poor of several grades. He believed that corporations could well set an example to other bodies by providing at a small cost, or even gratuitously, accommodation for their people. He would venture to condemn hasty conclusions on insufficient or improperly interpreted statistical data in reference to the benefits of sanatorium treatment. Such was, if nothing else, a most valuable education to all classes.

Dr. T. F. S. CAVERHILL (Edinburgh) gave the experience of that city and showed that in the artisan class, both among men and women, every fourth person died from tubercle. For these practically no sanatoriums were provided.

Dr. R. SHINGLETON SMITH (Bristol) was convinced that sanatorium treatment was vastly superior to any drug treatment. It was still necessary to preach the gospel of fresh air. Let fresh air come first and drugs second. Sanatorium treatment was greatly needed for the poorer classes for the arrest of the disease and the prevention of further infection. It was worth while to carry it out even for the poorest.

Dr. T. N. KELYNACK (London) believed that the original boom in sanatoriums was passing. He considered that the chronic tuberculous patient from amongst the working classes was often the best when considered from the economic point of view. He pointed out the question of the psychology of the poorer consumptive and that there was a danger of inducing a species of "consumptive casual" who went from institution to institution. The term "cure" was unjustifiable. The general health was much improved but the local state remained unaltered. A thorough inquiry into the whole subject was most desirable.

Dr. NATHAN RAW (Liverpool) pointed out what was being done in Liverpool with a very fair amount of success. [illegible] up the matter, boards of [illegible] ses in their provinces. Early diagnosis was greatly needed.

Dr. W. B. RANSOM (Nottingham) said that the whole matter turned on the questions of advantage and cost. He was certain that sanatorium treatment had come to stay. It enabled at least one quarter of those treated to have another four or five years' working life. He emphasised the necessity of after-care and the desirability that cases should be watched in a hospital for a month before being sent to a sanatorium.

Dr. C. E. REINHARDT (London) showed the magnitude of the subject and pointed out that it involved a huge financial question which was worth tackling and solving. He believed strongly in the chalet type of sanatorium as being cheaper and more effective than large buildings.

Dr. T. J. WHITESIDE HIME (Bradford) alluded to the decline in phthisis during the last 40 years and believed that much good came from preventive measures.

Dr. C. R. DRYSDALE (London), speaking from a long experience of the disease before the introduction of sanatoriums, was quite convinced of their value, but showed that with present accommodation it was quite out of the question to treat more than the fringe of the cases.

Dr. T. D. LISTER (London) referred to what was being actually done by one class of the poorer members of the community—the thrifty class. Dr. Weatherly had spoken of the German Industrial Assurance sanatoriums and their success. The nearest approach in this country to universal insurance was afforded by the great friendly societies and labour organisations. Some of the leaders of the great friendly societies in London inquired into the German system and visited the German industrial sanatoriums with Dr. A. P. Hillier. As a consequence a movement originated which resulted in the birth of the following scheme. It was proposed to erect a sanatorium for 200 patients suffering from early phthisis on a site of 250 acres which had already been acquired. About 60 patients will be allotted to a central sanatorium building in connexion with the administration departments, the remainder in "chalets," or rather "ward pavilions," of substantial but inexpensive construction, not of wood. The essential feature of the scheme was that before the building was opened every one of these 200 beds would be reserved, endowed, and maintained by levy on the members of the respective societies and organisations affiliated for this purpose in proportion to their respective needs. No cost for maintenance would fall upon the public. In the first expenses of erection and establishment of the institution help was being sought from the friends of the societies. The executive represented something like 2,000,000 workers. The Post Office had joined in the movement with about 25,000 of the employés in this department. To achieve success for the scheme three things appeared to be necessary. Firstly, early diagnosis, as all who had to treat phthisis knew only too well, was essential. Secondly, the coöperation of the patients was necessary and that would be obtained through their medical men and through their own trade journals and the magazines of the friendly societies by means of articles. The organisation of these societies and the superior intelligence of workers who think it worth while to join with their fellows should render this work fairly easy. Thirdly, there must be an attempt to prevent relapses. It was proposed to teach patients in whom the disease was arrested new occupations on the farms and otherwise on the estate and it was hoped that in this way selected cases might be fitted for a return to wage-earning under new conditions and arrest might be permanent.

Dr. J. E. MOLSON (Chelmsford) suggested that tuberculin treatment might be carried out in sanatoriums and showed how effectively Brighton was dealing with its cases.

Dr. KELYNACK read a paper on

Alcohol in Relation to National Vitality.

The public were deeply interested in the question and practical reformers were turning to the medical profession for direction and guidance. The conclusions of the recent Inter-departmental Committee on Physical Deterioration were dogmatic so far as alcohol was concerned. It was much to be desired that the recommendations should be carried out. The formulation by authoritative medical opinion of satisfactory and scientific teaching on the principles of temperance in the elementary schools was greatly needed. The Association had done much through its inebriates committee to secure many advantages for the inebriate and to advance national legislation and to secure the establishment of suitable institutions for both the curable and the irreclaimable classes of alcoholics.

The PRESIDENT of the section stated that from his student days he had been in accord with the dictum that alcohol was a poison and this was being conclusively re-proved by the many investigations of the present day. Alcohol did more harm to the community than any other agent.

Dr. DRYSDALE had always believed alcohol to be a poison and the whole of the profession was coming round to this conclusion. He believed that next to consumption alcohol claimed more victims than any other cause of disease.

Mr. W. MCADAM ECCLES (London), as one of those who presented evidence to the Committee on Physical Deterioration, pointed out that the conclusion in the report was decisive and one which deserved that the recommendations which were based upon it should receive prompt and emphatic attention.

Dr. ROBERT JONES (Claybury), as the other witness on the subject of alcohol before the Committee on Physical Deterioration, desired to emphasise the remarks of Mr. Eccles and to point out the convincing proof there was that alcohol was a terribly potent poison to growing tissues.

Dr. E. SYMES-THOMPSON (London) urged that action should be taken on the lines of the committee's report. The medical profession was a force in education which was of the greatest importance and if used in the right way must attain its object.

Dr. V. H. RUTHERFORD (London) said that it was interesting that no one appeared to be in favour of alcohol and that this attitude of the profession created a serious responsibility. He was sure it was necessary to reduce the temptation that existed on every hand towards alcoholism.

Dr. REINHARDT alluded to the fact that a few years ago he had difficulty in not giving alcoholic beverages to tuberculous patients in sanatoriums, but that now owing to the altered trend of public opinion it was quite easy to discard them and for the last two years none had been taken by any of his patients. In this and in other ways there was a distinct improvement.

Dr. J. WARD COUSINS (Portsmouth) said that in estimating the effects of alcohol on national vitality it was important to remember that only a very small proportion of the harm wrought was preserved in statistics, because the present method of death certification rendered it almost impossible that deaths due to alcohol could be fearlessly so recorded. The death certificate should be the confidential document of the State; then, and only then, would the true facts come to light.

Mr. W. SOLTAU ECCLES (London) felt that while instruction in temperance should be given in the elementary schools throughout the country the same should be available at the public schools. It was highly desirable that boys in the time-honoured public schools should not have alcoholic beverages placed before them.

It was then proposed by Dr. KELYNACK, seconded by Mr. MCADAM ECCLES, and carried unanimously, that the Council of the British Medical Association should be asked to appoint a committee to investigate the relationship of alcohol to national vitality.

Dr. H. R. KENWOOD (London) read a paper on

Hygienic Training and Teaching at School.

The ignorance among the poor of household management and of the principles of hygiene was responsible in no small measure for their high preventable mortality, their inferior physique, their intemperance, and their poverty. Education in these matters constituted an important measure in preventive medicine. What was wanted, as Sir John Simon said, was that education which by model and example would lead the poorer classes of society to know cleanliness from dirt, decency from grossness, which would teach them to feel the comfort and profit of sanitary observances, and would apply their instincts of self-preservation to the deliberate avoidance of disease. Healthy bodily development could be secured by physical exercises, combined with object lessons inculcating the recognised importance of fresh air, cleanliness, &c. A "sanitary conscience" should be created in the rising generation. Parents as well as the children would probably need instruction and to this end the employment of female health visitors was most desirable. There was a wide distinction between what was necessary for the teacher to know and what it was right for the children to be taught. One should impress simple hygienic rules upon the scholar, giving graphic reasons for the same, and he should be trained in hygienic habits while at school. What was adequate could probably be taught at the cost of one half hour per week during the last two years of compulsory school attendance, always providing that the scholar was receiving the object lessons of hygienic surroundings and practice during the whole of the school life. The aim, therefore, should be to instil elementary principles of hygiene which relate to the person and the home; as, for instance, the importance of, and the way to secure, fresh air, cleanliness of surroundings, person, habits, healthy bodily functions, suitable clothing, food, and temperance in alcohol. Female children should, in addition, be taught the principles of cooking, selection of food, and the feeding and management of infants. Few things more impress themselves upon the scholar than when one of their number is singled out for some special duty. It would therefore be a most telling thing if one scholar in each classroom were constituted the sanitary monitor for each week. It would be his duty to see that the ventilators were open, that the classroom was well flushed with fresh air upon every available opportunity, that cleanliness obtained, that dust did not accumulate, and that all sanitary requirements were observed in the use of the sanitary conveniences provided.

Dr. J. T. C. NASH (Southend-on-Sea) read a paper on

Shell-fish and Typhoid Fever

in which he made the statement that he was of opinion that a proper control of the production of shell-fish would secure a noticeable reduction of typhoid fever and a slight reduction of diarrhœa in the morbidity and mortality returns. Local evidence went to show that in Southend there was but little typhoid fever apart from contaminated shell-fish. The incidence of typhoid fever in London and Essex had diminished considerably during the last two years and this was coincidently with a lessened consumption of oysters and with improved methods of cooking cockles. At Southend much care was now taken with cockles which were collected at places remote from any recent sewage contamination. They were not relaid in polluted waters but were cleansed in pure water and steamed in galvanised iron coppers with lids for five minutes and all subsequent washings were carried out with pure water in clean metal receptacles. Consequently the reduction of typhoid fever in Southend during 1904 was about 90 per cent. as compared with the average incidence of many former years.

INDUSTRIAL HYGIENE.

THURSDAY, JULY 27TH.

Dr. J. H. BELL (Bradford) opened a discussion on

Anthrax.

He mentioned that the connexion of the British Medical

Association with the subject of anthrax dated from 1862, when Dr. William Budd of Bristol read a paper on the occurrence, hitherto unnoticed, of malignant pustule in England. In the following year Dr. Budd, at the request of the Association, drew up a memorandum "on the investigation of epidemic and epizootic diseases," in which he anticipated the discoveries of Lister, Pasteur, Koch, and others regarding the bacterial origin of diseases. At several later annual meetings of this Association papers on anthrax had been read, so that these meetings appeared to have been centres from which a knowledge of anthrax had been spread abroad. Dr. Bell then referred to the valuable researches of Dr. T. M. Legge on industrial anthrax in the Milroy lectures of this year. He drew special attention to the fact that a distinct and definite disease might repeatedly attack persons in a community and yet escape detection. Anthrax had come to them from the Far East and probably stalked abroad in this country for generations before it was recognised as a separate disease. In the year 1872, the year in which the maximum amount of dry hides was imported into this country, such an acute observer as Bryant of Guy's Hospital stated that he had no personal experience of the disease and yet surely many cases of both internal and external anthrax must have occurred among the workers in hides in that neighbourhood, which was close to the centre of the London anthrax district. In 1882, though the quantity of infectious dry hides imported had decreased, yet the number of fatal cases of anthrax increased, pointing to the fact that the disease was overlooked in the earlier period. In London anthrax districts workpeople had been educated to know the appearances of the cutaneous form of the disease and had been warned of the danger of slight injuries to the skin and of the importance of applying at once for medical treatment. Internal anthrax was very often not recognised until it was too late to avert a fatal result, the milder cases seeming so simple and like an ordinary cold. The diminished quantity of dry, dusty, infectious hides and the increased weight of wet hides imported had lessened the frequency of attacks and reduced the number of pulmonary cases. In Bradford the prevailing type of the disease had changed from the pulmonary to the cutaneous form, which was due, first to the greater care taken in foreign countries where the materials were packed to exclude "dead" fleeces, and secondly, to the precautionary regulations which had been enforced in factories where noxious materials were manipulated. Whether noxious wools and hairs could be disinfected by steam at 230° F. without injury to the material for manufacturing purposes was a question which remained to be tested scientifically. Dr. Bell predicted more than 25 years ago that pulmonary anthracæmia would be found at Kidderminster, Halifax, Norwich, Leicester, and other places, which prophecy had been fulfilled. He now ventured to predict that this form of anthrax would be found wherever persons inhale dust arising from infective materials, whether these be wools, hairs, hides, skins, rags, or anything else. The Factory and Workshops Act required the notification of all cases of industrial anthrax. It was very desirable that that notification should be extended and made to include all cases, industrial, agricultural, and others. This should be as complete and general as it was with regard to animals under the Diseases of Animals Acts. Dr. Bell suggested that in addition to the wool-sorting regulations, copies of which were placed in all wool-sorting rooms, a notice should be fixed on the wall of each room where possibly infective materials were manufactured advising workpeople of the symptoms of external anthrax and of the importance of seeking medical advice at once if there was any suspicion of infection. With regard to treatment, the remedy for all kinds of anthrax was at present Professor Sclavo's anti anthrax serum, introduced into this country by Dr. Legge and commented on in his Milroy lectures. Many cases of cutaneous anthrax recovered without medical or surgical treatment; a greater proportion recovered if the lesion had been excised, but the greatest number recovered when excision was combined with injection of serum. For internal anthrax serum was the only remedy. Unfortunately, the patients were generally dying before the diagnosis could be made, when it was too late to do any good. Dr. Bell therefore recommended that when persons who had been exposed to anthrax infection were taken ill the illness, no matter what its nature, should be reported to the manager of the department at once; that the patient should be seen by a medical man on behalf of the firm; and that in all cases, except where anthrax could be positively excluded, 40 cubic centimetres of serum should be injected at once and repeated if necessary to determine the diagnosis. By this treatment in the earliest stages of the disease before a correct diagnosis could otherwise be made some lives would be saved and so far employers would be relieved of the incubus of the Workmen's Compensation Act.

As Mr. J. L. STRETTON (Kidderminster) was unavoidably absent his remarks were read by the honorary secretary, Mr. C F. BRYAN. Mr. Stretton laid stress upon the difficulty of diagnosis of the disease and said that it would be an advantage if permission could be obtained to perform inoculation experiments in centres where anthrax was likely to occur. It appeared that cases of anthrax occurring in workers in factories must be reported to the Home Office, cases occurring in other human beings were not reportable at all, and cases occurring in cattle must be reported to the Board of Agriculture. Here they had three sets of cases, two of them governed by a dual authority, which was always unsatisfactory, and the third under no control whatever. Mr. Stretton referred to several cases in illustration of this point which had occurred in his private practice. One was that of a youth who worked in a garden and became infected with anthrax. It was ascertained that a brother who occupied the same bed was employed in a factory sorting Persian wool. This case was not notifiable, so the presence of anthrax in the factory would be unknown to the Home Office. Many cases in animals were due to the refuse from factories being used as manure; but as these were not reportable to the Home Office it might be unaware of the fact. The Home Office took no action with respect to the infected individual. The Board of Agriculture slaughtered animals affected with anthrax and cremated the bodies. This method of disposal of bodies should apply to human subjects also. All cases should be reported to the same authority and action ought to be taken with regard to the infected body, the domicile, and the fomites. The treatment of these cases should not be conducted in the wards of a general hospital. Special wards should be provided by the manufacturers and insurance companies who were the gainers by efficient treatment. Professor Sclavo's serum was a great advance and for cases of anthracæmia and malignant anthrax œdema was the only treatment which they could adopt. In malignant pustule it was their only hope where it was impossible to excise the pustule but when excision was possible it should be practised in addition to inoculation.

Dr. W. H. HORROCKS (Bradford) remarked that many cases of both external and internal anthrax were unnoticed, which fact must vitiate any statistics on the subject. As regards anthracæmia a peculiar state of well-being occurred which was very deceptive and generally preceded a fatal issue. He agreed that treatment should be a combination of serum and excision when possible.

Dr. DAVID GOYDER (Bradford) mentioned the results of the commission on wool-sorters' disease appointed by the Bradford Medico-Chirurgical Society and the necessity in treatment of some such serum as that advocated by Dr. Legge. The course of internal anthrax was so rapid and the insensibility of the patient to his dangerous condition was so complete that he was rarely seen by a medical man until he was in the jaws of death. There was no time for treatment in that case. All other kinds of treatment had been tried but nothing had answered until this serum was introduced and he advocated an extended trial of its efficacy.

Dr. H. W. LANGLEY BROWNE (West Bromwich), the President of the section, said that he had not had much experience of anthrax, as he did not live in a district where it was common. He found benefit in external cases from antiseptic treatment and was accustomed to apply strong iodine liniment with a brush to the part affected and over that gauze soaked in a 1 per 1000 solution of perchloride of mercury, then cotton-wool, and a firm bandage over all.

Dr. BELL, in reply, laid stress upon the early injection of serum and upon the importance at the same time of excising the affected part in external anthrax. He did not agree with Mr. Stretton that cases of anthrax should not be admitted into the wards of a general hospital.

GYNÆCOLOGY AND OBSTETRICS.

WEDNESDAY, JULY 26TH.

Dr. HERBERT R. SPENCER (London), the President of the section, opened the proceedings by welcoming their guests, Professor Howard Kelly Professor Wertheim (Vienna) and

(Baltimore). He alluded to the pathological museum in its gynæcological aspect and thanked Dr. Louisa Garrett Anderson for her efforts in that direction. He then called upon Professor WERTHEIM to read his paper on

The Diagnosis and Treatment of Cancer of the Uterus,

and thereby to open the discussion set down for the section. Professor Wertheim began by describing the steps of his operation by means of some excellent drawings as follows: (1) the vagina was disinfected and the growth on the cervix dealt with in a like manner; (2) the abdomen was then opened; (3) the rest of the peritoneal cavity was carefully packed off from the area of operation; (4) the posterior layer of the broad ligament was opened and the ureter carefully and gently isolated; (5) the peritoneum on the front of the cervix and bladder was reflected forward; (6) the peritoneum on the posterior aspect was treated in a like manner; (7) the tubo-ovarian and infundibulo-pelvic ligaments were then tied and divided and bleeding vessels were clamped; (8) the finger was passed under the broad ligament along the ureter and the uterine vessels were felt and secured; (9) the vagina below the cervix was clamped by his clamps and the uterus and vaginal reflexion removed; (10) the bleeding from the vaginal stump was arrested by sewing round the cut edge; (11) the glands around the iliac vessels were removed; (12) the wound area was packed with gauze brought out through the vagina; (13) the peritoneum of the pelvic floor was closed; and (14) the anterior abdominal wound was closed in the usual way. If the ureter was injured or sloughed as the result of interference it would be necessary to perform nephrectomy and those cases (three) in which he had to do nephrectomy had borne the subsequent operation satisfactorily. He showed tables of exhaustive and singularly searching statistics bearing on the operation on 179 cases and clearly demonstrated that in this series of what were considered hopeless inoperable cases by the vaginal operation that quite 30 per cent were free from recurrence after five years and if certain factors were taken into consideration some of the cures showed a rate of 70 per cent. of five years' cure-limit. In the matter of diagnosis the importance of early recognition if necessary by curetting and microscopic examination was insisted on. With regard to treatment: (1) it was established that the results to be obtained by his abdominal hysterectomy considerably surpassed the results of vaginal extirpation of the uterus; many cases operated on by the abdomen were inoperable by the vagina; (2) the cause of the greater result was chiefly to be attributed to the fact that in addition to clean operating the surrounding tissues were taken away by the abdominal operation; (3) the extirpation of the cancerous regional glands appeared to be of some relative value, most of the cases in which the glands were not taken away recurring and in those cases in which the glands were taken away few recurred; time would show the real or supposed value of removing the glands; and (4) with regard to the mortality of the abdominal operation simplicity of technique and shortened anæsthesia were important. In his hands the mortality had fallen from 15 to 7 per cent. lately. Vaginal hysterectomy was still of value in cases of early cancer of the cervix and in cancer of the body of the uterus, but in more advanced cases of the cervix the abdominal operation was needed as the cancer was more virulent than in the body of the uterus, and the parametric tissues should be removed.

Professor HOWARD KELLY complimented Professor Wertheim on his paper and said that he had, acting with Dr. John G. Clark, recommended the removal of the glands, just as in cancer of the breast. The ureter should not be separated from end to end, as it was supplied by adventitious vessels from the surrounding tissues, as shown by the collaboration with him of Dr. Sampson. He inserted ureteral catheters before operation in order to keep the ureter in touch. He tied the uterine vessels at their origin, always handling the ureter as gently as possible. He approved of the preliminary curettage and used the formalin tampon. He packed off most carefully the wound area from the peritoneal cavity owing to danger of infection from the septic cervix uteri. The mortality of the wide operation was very large and would be so in the hands of men who had not large experience. The public should be educated to come for surgical assistance early in the disease. Cancer was mainly a disease due to unsatisfactory surroundings, just as tuberculous and other diseases were due to insanitary surroundings.

Dr. LOUISA B. ALDRICH-BLAKE (London) complimented Professor Wertheim and Professor Kelly. She gave particulars of 16 cases of her own. After vaginal hysterectomy recurrence occurred in the scar or in its immediate neighbourhood. She had not systematically removed glands and was not yet satisfied of the real value of the proceeding. She had noted glands in the broad ligament and found them always infected with carcinomatous cells. The operation was mainly on the lines detailed in Howard Kelly's "Operative Gynæcology." She made the cervix and vagina as clean as she could and then regarded it as unclean and was very careful to prevent infection of the operation area. She did not curette all cases, but she disinfected the cervix as far as she could, always bearing in mind that the best means at hand were very deficient in results. She had wounded the bladder twice, once wilfully in order to remove growth in its wall and once accidentally.

Dr. SKENE KEITH (London) thought that the Trendelenburg position was undoubtedly the best for the abdominal operation. He did not believe in a very extensive operation as it was more difficult than appeared to a casual observer and should only be done by men of wide experience.

Dr. CUTHBERT LOCKYER (London) had operated on cases in which he had to leave cancerous material in the parametrium and recurrence, of course, took place. The uterus should always be removed when possible. He used drainage of the vaginal vault, which was not closed. He found that cutting instruments tended to cause recurrence and for that reason used the galvano cautery in removing the uterus.

Dr. MARY SCHARLIEB (London) complimented Professor Wertheim on his valuable paper and said that she had hitherto done mostly vaginal hysterectomy, but now she had taken to the abdominal operation on account of the facilities and advances which it clearly offered. At this section last year she was the only person, with the exception of Dr. Forbes-Ross, who advocated the abdominal operation, which she considered was a more complete, thorough, and workmanlike proceeding and for that reason alone deserved a fair and extended trial.

Dr. JOHN CAMPBELL (Belfast) said that what he had heard had led him to feel somewhat more hopeful. He regretted that many cases were too far gone for the vaginal operation. He trusted that these far-advanced cases would now be attempted by the abdominal route, as clearly Professor Wertheim had made out an excellent case in favour of the abdominal proceeding.

Professor HENRY BRIGGS (Liverpool) gave details of 161 cases. He said that under five years the mortality from recurrence was very high. He did not believe in the efficacy of styptics, douches, &c., but "specimen" gauze should be worn by the patient and thus bleeding would early come under notice. The significance of the fact that the glandular elements dipped down into the musculature of the uterus was such that diagnosis was made more difficult In this matter adenoma, endometritis, and cancer were very close to one another. He mainly performed the vaginal operation and did not do other than keep an open mind on the matter of the abdominal operation. He had operated on many far-advanced cases purely at the request of the patients and their friends as a last hope and chance.

Dr. F. J. MCCANN (London) did not approve of the idea of issuing pamphlets on cancer to educate the public as it would tend to create anxiety in women and perhaps lead to an increase of cancer by nervous agencies. Great attention to every discharge in a woman should be paid. Cases did come early for discharge but examination was not made by the medical attendant. He thought that a more extended application of the supra-vaginal operation was valuable, and it really had a place and could cause a period of immunity extending over five years. He advocated a free removal of the vagina by the vagina if the vaginal mucous membrane was infected.

Dr. HERBERT SNOW (London) agreed that pamphlets concerning cancer should not be issued to the public. Many cases of hysterectomy for cancer were often cases of tubercle, &c., and the microscope should be always used to confirm diagnosis. He thought that cancer was due to mental distress and worry. He did not believe in radium and high tension electricity in cancer.

Dr. J. INGLIS PARSONS (London) said that the mortality after operation for cancer had in spite of experts gone up and that 23,000 persons in the United Kingdom still died from cancer annually. He always used the cautery in removing carcinomatous tissue as the knife tended to cause spread of the disease. After extensive operations the growth of the recurrence was more rapid. He had used sodium salicylate in inoperable cases and had reason to think that it did some good based on the idea that the disease was parasitic. Microscopic examinations of the uterine mucosa should always be made before resorting to removal of the uterus

Dr. ROSENWASSER (Cleveland, Ohio) said that he had seen Professor Wertheim's work and had had his doubts concerning the abdominal operation removed. The secret of Professor Wertheim's success was that the patients were prepared for operation for some time before. Professor Wertheim removed the vaginal cervix by the actual cautery whilst yet the woman was conscious and without the aid of an anæsthetic. The abdominal operation only ought to take from one to one and a half hours. He was convinced that the abdominal operation had a great future.

Dr. F. W. FORBES-ROSS (London) said that at this section last year Professor Olshausen had advocated vaginal hysterectomy as being more desirable than abdominal hysterectomy and that Mrs. Scharlieb had entered a strong plea on behalf of the abdominal operation when he (the speaker) had pointed out the facility gained by the abdominal operation for the removal of glands and diseased tissues. Since then Jacobs had addressed the Gynæcological Society in London strongly advocating the abdominal route and now Professor Wertheim had given them a valuable paper embodying his work since 1898. Dr. Forbes-Ross could not agree with some of the speakers that glands need not be removed, they ought to be removed just as much as those (in the axilla and in the neck) enlarged after cancer in the mamma or tongue and lip. The fact that Professor Wertheim found some cases with the parametric tissue, distensible and not infiltrated with lymphocytes but with many cancer cells present and others with no cancer cells but many lymphocytes was most interesting, and although Professor Wertheim had not said so he felt sure that the lymphocytic infiltrated cases were those that did better than the first class.

Dr. MARY THORNE (London) said that she agreed with Professor Wertheim that prolonged anæsthesia was not good for the patient as it caused fatigue and tended to unfavourable results.

The PRESIDENT of the section thought that sufficient praise could not be given to Professor Wertheim for the finest work yet done in operation for cancer. Professor Wertheim had brought every case he had operated on to notice and 30 per cent. were free from cancer after five years. He (the speaker) had removed the uterus per vaginam by the galvano-cautery and preferred it. The facts of the abdominal operation could not be got away from and the paper was an epoch-making one, yet there were other operations which could be done as well as the abdominal operation. It was the greatest paper that had ever been written on cancer of the uterus, or, indeed, on cancer anywhere in the body.

Professor WERTHEIM replied, thanking the meeting for the kind reception given to his work and to his paper and said that when the remarks were published he would reply to them publicly after taking time to consider them.

THURSDAY, JULY 27TH.

The proceedings were opened by an instructive and interesting lantern demonstration by Dr. S. J. CAMERON (Glasgow) on

Some Complications and Degenerations of Fibro-myomata.

Primary carcinoma of the Fallopian tube complicating uterine fibroids.—The growth was situated in the ampullary region of a greatly elongated Fallopian tube, while the uterus contained many fibro myomata. The growth arose from the anterior wall, having the posterior and superior wall stretched over the tumour but not infiltrated by it. Four inches of unimplicated tube intervened between the tumour and the uterus. The microscopical examination showed the growth to be a carcinoma and the tube wall in the neighbourhood of the tumour showed changes similar to those seen in cases of hydrosalpinx, and these changes, combined with the shape of the tube and the position of an uninvolved ovary situated in its concavity, lead Dr. Cameron to believe that the carcinoma was secondary to a hydrosalpinx. *Sarcoma.*—This tumour was removed by Dr. Cameron from a patient, aged 62 years, who had known of the presence of a uterine tumour for a period of 29 years. The growth was soft and cheese-like, mucilaginous material escaping from a part of the tumour surface when incised. Portions of the growth had a vermilion tint and the blood-vessels in the broad ligament and underlying the peritoneum were of large size. The histological examination showed the growth to be highly cellular, most of the elements having a fusiform shape. A lantern slide from the central portion of the tumour showed fibromyomatous débris infiltrated by these cells. Numerous giant cells were noted. *Carcinoma of the body of the uterus.*—Dr. Cameron had to extend his series to Case 104 before meeting with this complication, although he noted from the reports of other gynæcologists the undoubted tendency that carcinoma of the body had to form in fibromyomatous uteri. In most of the pathological specimens seen by him the growth had been diffuse, but this he considered was due to the fact that such patients had sought relief when the disease had been present for a considerable time. He referred to the difficulty of distinguishing adenocarcinoma of the cervix from these cases. Pain he considered to be a fairly early symptom in carcinoma of the body, although there were cases in which the disease had advanced considerably before any marked discomfort occurred. *Change in the uterine and ovarian arteries.*—Frequently great increase in size of those vessels occurred. Endarteritis as a rule was not very severe, while the circular and longitudinal muscular coats were much thickened. The souffle present in cases of fibro-myoma he considered to be situated most commonly in the uterine and ovarian arteries and less frequently in the vessels underlying the peritoneal covering of the tumour. In support of this statement (1) he had in two cases felt pulsation in the large vessels of the broad ligament through the abdominal wall and here the murmur was situated. At operation the broad ligaments were found to be elevated by the tumour growth. (2) With a very moveable tumour the pitch of the note might be altered by changing the position of the growth. (3) It was often best marked in cases where the tumour had undergone cystic change, so that it could not be due to circulation in the tumour. (4) He had noted its presence in a case of ovarian cyst where the pedicle at operation was found to be thick and vascular. *Cystic degeneration.*—He did not consider that this was due to thrombosis of the vessels and pointed out that confusion might arise in designating a fibroid as necrobiotic when the change present might be one of œdema and diffusion of blood pigment. He showed photographs of a fibroid where cystic degeneration had occurred in the capsule proper, and from photographs of museum specimens he showed that probably peripheral calcification of the growth would take place in some instances, and he demonstrated that perforation of the uterine wall might result. The histogenesis and the occurrence of mast and other cells were demonstrated in fibroids undergoing cystic and myxomatous change. *Torsion of the pedicle of a subserous myoma with rotation of the uterus.*—The tumour was removed by Dr. Cameron on the sixth day of illness. It weighed four and a half pounds and the pedicle had been twisted three times, the uterus rotating from right to left so that the right appendage lay to the left of the middle line. A few recent adhesions and a small amount of free fluid were found on opening the abdomen. The tumour was deeply injected but whorling was distinct. Great venous engorgement existed and on microscopical examination the smallest capillaries were found to be dilated, while at parts the vitality of the muscular tissue had been affected. The nuclei in the less affected portions stained deeply but in the parts which had suffered most the nuclei had disappeared. *Chronic torsion of the pedicle with omental adhesion to a calcified tumour.*—The pedicle in this case was long and peripheral calcification with central liquefaction had taken place in the fibroid. The omental adhesion was broad and the tendency to enlargement of the vessels with atrophy of the omental tissues was demonstrated. Such cases might prove dangerous through (1) direct injury to the viscera; (2) strangulation of a portion of the intestine; and (3) rupture of the vessels during the different positions occupied by the uterus during labour. *Fibro-myomatous polyp complicating a three months' pregnancy.*—The patient complained of bleeding of three months' duration. There was no history of amenorrhœa. A fibro-myomatous polyp three inches long occupied the vagina and the day after its removal the patient aborted. Stratified squamous epithelium covered the most dependent portion but along the pedicle the covering was represented by decidual tissue. Between the muscle fibres here and there a group of decidual cells was found. From the examination of this specimen Dr. Cameron concluded that in cases of fibro-myomatous polypi complicating pregnancy the so-called mucous membrane of the polypi might undergo changes analogous to that in the uterine cavity. *Localised telangiectasis with tuberculous disease of the ovaries and tubes.*—Some parts of this tumour had the structure of an ordinary fibro-myoma but by far the greatest part of it showed a telangiectatic change. Besides this pathological condition well-marked tuberculous lesions were shown to exist in the tubes and ovaries. *Adeno-myoma of the uterus.*—A number of slides were shown to illustrate the pathological peculiarities of this variety of tumour. In one the origin of the tumour from the endometrium was demonstrated and a cervical adenomyoma with marked gastric distension of the spaces was also exhibited. One tumour showed an adenomyomatous structure at one part and an adeno-carcinomatous form at another portion. These tumours give rise to excessive hæmorrhage and in the experience of others the removal of the ovaries produced no abatement. Most of them could be recognised easily by naked-eye examination as they differed from ordinary fibroids in having no whorling or capsule proper. Uterine fibrosis resembled it, however, but in fibrosis the uterus was smaller and its microscopical characters were entirely different.

Mr. E. HASTINGS TWEEDY (Master of the Rotunda Hospital, Dublin) next read a paper entitled

The High Range of Normal Temperature and Pulse throughout the Puerperium.

In the course of this paper he pointed out that success in obstetrical practice as it existed in the large maternity hospital or in the district of the private practitioner was more accurately gauged by a low percentage of morbid cases than by any septic mortality table In pre-antiseptic times men practised midwifery for long periods with an entire freedom from septic mortality and these periods of immunity extended also to the maternity institutions. Thus, in 1766, 611 women were delivered within the walls of the Rotunda Hospital with a maternal mortality from all causes of three and statistics based on a death-rate alone would make many years in the eighteenth century compare favourably with present-day figures. This in spite of the fact that maternity patients were often placed two in each bed and that contaminated water and a foul cesspool supplied the wants of the hospital. It was certain, however, that these ancient statistics gave us no indication of the true state of affairs in respect to sepsis as indicated by a morbid pulse and temperature. Some temperature charts of the year 1880 were still in existence and a reference to the ward books of this period proved conclusively that the hospital was in a more than usually healthy condition at the time. Carbolic acid and Condy's fluid were in general use and the hygienic condition of the institution had markedly improved. On analysing these charts it was found that just one-half showed morbidity (48 out of a total of 99), the temperature in nine of these 48 cases reached up to or above 105° F. and 18 more up to or above 103°, whilst amongst those cases which were recorded as normal such notes as the following frequently occurred:—Chill, erysipelatous patch over buttocks. Succession of chills, headache. Chills, lochia fœtid and scanty. Series of chills, face flushed, lochia very fœtid and scanty, &c. In spite of these indications of unhealthiness the period was singularly free from maternal mortality and if figures prove anything these prove that the majority of women will pass through the child-bearing ordeal notwithstanding their septic condition, although their constitutions would inevitably bear unmistakable indications of the ravages of this dread disease. He contrasted these figures with his present-day statistics which showed for the six months ending April 20th, 1905, that amongst 918 women delivered in the hospital there were 58 cases recorded as morbid. An analysis, moreover, of these 58 cases showed his results to be still more favourable than the bald statement of these figures would lead them to believe. In 43 instances the temperature and pulse did not remain above the normal for longer than four days; in five more for longer than five days; none of the cases proved fatal or gave rise to any anxiety; and the longest recorded rise of temperature, due to acute Bright's disease, lasted but 21 days. Considering, then, the importance of this subject, Mr. Hastings Tweedy urged that a common basis for determining morbidity should be arrived at by the heads of the maternity hospitals throughout the British Empire as well as by private practitioners. His present method for determining this last worked with smoothness and absolute accuracy throughout the year. It was based on an estimation of the pulse and temperature for 24 hours counting from the beginning of the second day of the puerperium. A temperature above 99° accompanied by a pulse above 90 indicated a morbid state if recorded on three successive occasions. His charts were arranged so as to make these two records apparent at a passing glance and it was certain that a serious condition of septic ill-health would be detected with absolute certainty by these records. He concluded by expressing a hope that others would adopt these limits and thus enable the statistics of the British Empire to harmonise.

Professor J. W. BYERS (Belfast) thought that there should be a standard to guide them as to puerperal sepsis—that is, when they should apprehend its onset—the standard being a temperature of 99° F. and a pulse of 90. In operative midwifery, if extreme care was not taken, evidences of sepsis would arise.

Dr. HENRY CORBY (Cork) said that the pulse and the temperature should be taken and read together, and that the pulse was the more important of the two, especially in peritonitis, puerperal or otherwise. They were, perhaps, too strict in keeping patients lying down too long; of course, the liability to pulmonary embolism and prolapsus uteri, &c., should be borne in mind. Of great value was the getting up of a woman as soon as possible after it was safe, thus facilitating drainage, &c.

Dr. R C. BUIST (Dundee) said that a standard should be fixed and used as a guide in lying-in hospitals and elsewhere.

Dr. R. BOXALL (London) also agreed that some standard should be adopted.

The following motion was proposed by Dr. BUIST and seconded by Professor BYERS:—

> That it is desirable that a standard of puerperal morbidity be arranged for lying-in hospitals and that the Council be requested to appoint a subcommittee to consider the matter.

Dr. THOMAS WILSON (Birmingham) did not think that the Association was the body to set up a standard but that the obstetrical societies of England, Scotland, and Ireland should be the bodies to do this.

Dr. FORBES-ROSS (London) agreed with Dr. Wilson in his remarks.

Dr H. C. TAYLOR YOUNG (Sydney, New South Wales) did not agree and did not see why the Association should not carry out the terms of the proposition submitted.

The PRESIDENT of the section then put the proposition to the section which was carried *nemine contradicente*.

Dr. WILSON then read a paper entitled

Two Cases of Vaginal Cæsarean Section in the last Two Months of Pregnancy, with Especial Reference to Vaginal Cæsarean Section.

He stated that in the last two months the uterus with its contents was so large that until recently it had been considered impossible to remove it through the vagina, but Dührssen's method had cleared away this difficulty and it was now possible to operate through the vagina even at the full term of pregnancy. In the last months of pregnancy in association with operable cancer of the cervix there was now, therefore, a choice of three methods of hysterectomy—abdominal, vaginal, and combined. The relative advantages of these methods were discussed and reasons were given for preferring the vaginal route. Two cases were related in which operation at the eighth month was performed successfully as regards both mothers and children. In conclusion, Dr. Wilson pointed out that the choice of operation in pregnancy would depend upon the method generally adopted by the operator in cases of cervical cancer. Even in the last months the operation of vaginal Cæsarean section was not a difficult one in suitable cases. The ultimate choice of operation in these cases would depend upon the remote results as regarded recurrence of cancer and until time had enabled these to be estimated and compared the question of the best method of operating, abdominal or vaginal, must remain an open one.

Professor WERTHEIM said that he had operated on six cases. In each case the ordinary abdominal Cæsarean section was performed and then the uterus and parametric tissues were removed. All the cases did well and recovered, which was really satisfactory as cancer complicating pregnancy was particularly virulent.

The PRESIDENT of the section said that Dr. Wilson's paper was one of very great value. There did not appear to be any very considerable difficulty in doing the operation. If, however, the patients died from recurrence soon after it, and lived longer if delivered naturally without removal of the uterus, Professor Wertheim's cases showed that perhaps the abdominal operation would in the future turn out to be the proper operation. He thought that, if possible, the uterus should be allowed to dilate. There were disadvantages of this, however, such as rupture of the uterus. After the puerperium, in which he had seen a cancer become much smaller, perhaps Professor Wertheim's operation could then be more safely and more radically done.

Dr. WILSON replied and said that the cancer might advance during the puerperium.

The PRESIDENT of the section said that his experience was that the cancer retrogressed during the puerperium.

Dr. CAMPBELL then read a paper entitled—

The Influence of the Presence of Pus in the Female Urethra on the Progress of Gynæcological and Obstetrical Cases.

He said that the general practitioner should realize how prevalent pus in the urethra was, both among gynæcological and parturient patients; how frequently that pus contained virulent septic micro-organisms; and how readily it might be the cause of chronic gynæcological ailments and of puerperal septic conditions. In 544 consecutive cases examined in private practice 135 had pus in the urethra or in Skene's glands—i.e., 24·7 per cent. In 372 consecutively examined in hospital practice 135, or 36·2 per cent., had pus in the urethra or Skene's glands. The result of this examination was that in the total 916 cases 29·4 per cent. had pus in the urethra or Skene's glands. In 120 labour cases examined specially for him by Dr. John McLiesh, 18 of them, or 15 per cent, had pus in the urethra and Skene's glands. In 100 cases of pus in the urethra or Skene's glands Dr. T. Carnwath had found staphylococcus pyogenes albus in 96 per cent., streptococci in 6 per cent., and gonococci in 2 per cent. Many of the cases showed mixed infections—a patient with pus in her urethra was practically in the position of a woman with a septic sinus discharging into her vagina and required special precautions during her confinement.

Dr. WILSON said that he had for years attended to, and thought very deeply on, the question of the clinical significance of the presence of pus in the female urethra. He considered that the clinical explanation was the same as that in the case of the male gleet. He was of opinion that experts should be more often on the look-out for pus in this connexion.

Dr. BOXALL said that at the General Lying-in Hospital, York-road, London, these cases did not occur, but at the Queen's Charlotte's Hospital in London, where every case was not treated as possibly septic and mercurial douches were not used before delivery, perhaps that was the reason why septic gonorrhœal cases sometimes arose. This was the explanation which he gave when asked by the staff of Queen Charlotte's Hospital to explain the absence at York-road of septic cases which occasionally arose at the Queen Charlotte's Hospital. Those cases were perhaps cases with pus in the female urethra.

Dr. CORBY read the account of a case entitled,

Case of Fibroid of the Ovary from a Hermaphrodite,

with photographs, which was very interesting and instructive.

OPHTHALMOLOGY.

WEDNESDAY, JULY 26TH.

Mr. GEORGE A. BERRY (Edinburgh), the President of the section, after welcoming the members, said: Fifty years ago such rapid strides were made in the science of ophthalmology and in ocular therapeutics that every year brought its record of important discoveries in diagnosis, of new methods of examination, of far-reaching generalisations, often of real advances in ophthalmic surgery. At that time, indeed, a few years sufficed to revolutionise the whole science of this department of medicine until ophthalmology attained to a degree of perfection which led von Helmholtz to say of it that it was "the most strictly scientific department of medicine, the one which most nearly approached to the exact sciences." That ophthalmology can hardly with the same justice be said to occupy so prominent a position at the present day is due to the rapid advances which have been made more recently in other departments of surgery. Some few advances in our special science are, no doubt, of comparatively recent date—e.g., the introduction of antiseptic and aseptic measures in connexion with injuries and operations; the use of cocaine as a local anæsthetic; the appreciation of the rôle played by microbes and the toxins which they engender in connexion with various inflammations of the eye; some few points in pathology, notably with reference to tuberculous manifestations; the use of the electro-magnet for the removal of particles of iron and steel, and the application of the Roentgen rays for their detection and localisation. From the therapeutic point of view, however, there has been but little advance to record; whilst our knowledge of the connexion between diseases of the eye and diseases of other parts of the body is hardly less crude than it was 50 years ago, except perhaps as regards ocular manifestations in certain nerve disorders. Latterly, indeed, instead of leading the way the ophthalmic surgeon has mostly had to follow and to adapt to the requirements of his own specialty the advances, so far as they are at all applicable, which have extended the sphere of general surgery. This comparatively slow advance of recent years is not due to there being nothing left to find out. It is not due to the interest in the special subject of ophthalmology being, for the time, diverted to branches which seem to offer more scope for research. There is at least no dearth of writings on special ophthalmological topics. It is not due to the absence of experimentation with new therapeutic agents; new drugs are constantly appearing which, if they do not succeed in doing a tithe of what is claimed for them, at least raise hopes for the time being. Not a few books devoted exclusively to the consideration of new remedies have appeared quite recently. Even in connexion with diseases of the eye, however, for which it should be possible to estimate the results of treatment, in many cases at least, more fully than for other less accessible organs, there is so often shown the same absence of critical insight into the difficulties of such investigation which seems to characterise the majority of writers on therapeutics. Notwithstanding discoveries in pathology, we make, it must be admitted, but slow progress in treatment. The problems which for us await solution are in point of fact numerous enough but they are for the most part such as seem only likely to be solved when our knowledge of general pathology and medicine has reached a stage or two further than it has at present. We do not even know yet what it is that determines the selection of certain organs and tissues for the manifestation of certain definite pathological processes. We are consequently and necessarily empirics as regards the manner in which we may try to supplement purely local by more general means of treatment. But if we cannot to-day check the progress of an optic atrophy or treat on anything but empirical lines a choroiditis, if we cannot prevent the development of a detached retina, if we cannot even cure a conjunctivitis, we may surely hope that some day it will be possible to do all these things and more. If our progress is slow it is none the less real. We need to be critical, even sceptical, in view of the flood of literature from which we must separate the chaff from the wheat. But we can afford to be, we have reason to be, optimistic as to the future. My own predilections have always been for surgery. There is so much pleasurable interest to be got from watching the effect of surgical interference of any kind, so little satisfaction in cases which reliance has to be placed on medical treatment alone, that we are prone to forget that the laborious, patient investigations of recent times may, in the perhaps not distant future, turn the tables on surgery. We may some day have to admit that many conditions, for which surgical measures seem the only suitable ones at present, will allow of rational successful treatment on medical lines alone. Much of our treatment at the present time may even in the light of future knowledge be of a nature which, if it were then adopted, would be little less than criminal. The present discussions might not perhaps lead to much, yet they sometimes help to lift us out of the groove of self-satisfaction and to correct a tendency inherent in man to think that the only "sensible" men are those who hold the same views as ourselves.

Dr. ADOLPH BRONNER (Bradford) read notes of

A Case of Slight Myopia

in which distressing local and general symptoms were relieved by the use of glasses which were much too strong. He said that recently much attention had been drawn to the use of correcting glasses for the relief of obscure nervous symptoms. In America "heterophoria" and in this country "errors of refraction" were the presumed causes of the trouble. The case he detailed illustrated well the dangers of accepting some of the marvels published without proper investigation. A young man suffered from headache on reading, his position at work was bad, and he stooped greatly. He obtained glasses which compelled him to sit upright and his symptoms disappeared and his general health was improved. Examination of the eyes showed that he was emmetropic. The glasses worn were concave sphero-cylinders which appreciably diminished his vision both near and far, but by reason of the former effect they compelled him to sit up when reading. Original examination of the case by a competent observer would have shown the true nature of the disability and the cure would have been natural and easy.

Mr. E. E. HENDERSON (London) read a paper on

The Influence of the Size of the Pupil as Produced by Atropine or Eserine on the Circulation of Intraocular Fluids.

After describing the apparatus which he and Professor Starling used in this research he said that their experiments showed that the raising of the pressure of the living eye artificially increased the rate of filtration. This depended upon several factors: one that had not previously been taken into account was the condition of the pupil as affected by atropine or eserine. The rate of filtration was always greater at artificially raised pressures when eserine was used than when atropine was instilled. These effects, he thought, were not merely mechanical since they differed from the results obtained by similar experimentation with dead eyes.

Mr. N. BISHOP HARMAN (London) read a paper detailing his experiences with various forms of

Electrical Treatment of Trachoma at the Middlesex Hospital.

They had there an unrivalled equipment and no pains had been spared by Mr. C. R. C. Lyster, the surgeon in charge, and his staff. Seven cases had been treated by the high-frequency current by direct contact of the electrode to the affected mucosa; in some cases the applications had numbered over 80. By the x rays four cases had been treated; in each case a current of such quality was used as would give the maximum of the x rays without the dangerous burn rays; up to 50 sittings of ten minutes each had been given. With radium two cases had been treated by direct contact of the glass capsule containing the salt; the applications in one case numbered 139. Despite all this labour and care no beneficial results had been obtained; in every case in which the particular treatment was persevered with steady deterioration was noted, and in two cases of an original unilateral affection the second eye of each case became seriously affected whilst the x rays were being exhibited. His conclusion was expressed by his return to the use of silver solutions, the use of the bluestone crayon, expression, and scraping.

Mr. C. DEVEREUX MARSHALL (London) had used both the x rays and radium; in each case treated he had used the bluestone crayon on the other eye by way of control. He was not convinced that the new forms of procedure were of any use; they were certainly not so effective or so rapid as was bluestone.

Mr. CYRIL H. WALKER (Bristol) asked whether relief of the pain of trachoma could be obtained by the x rays and what use could be made of the low tension tube.

The PRESIDENT of the section had seen radium in use for the treatment of lupus in Paris; it was strapped on to the affected part for four hours and not for five or ten minutes as practised by Mr. Harman.

Colonel E. F. DRAKE-BROCKMAN (London) referred to his Indian experiences of the treatment of the disease. He thought the use of bluestone severe and preferred silver solutions, particularly the new colloidal preparations.

Mr. BISHOP HARMAN, in reply, said he did not find that the use of the x rays relieved the pain of trachoma; he would not use low tension tubes on account of the serious risks which they entailed of burns. As regards the length of time of the application of radium that depended on the quantity used and the sensibility of the part to which it was applied. He agreed that the use of bluestone might be cruelly rough but because it was sometimes badly used that did not diminish its value in careful hands. He did not place much value upon the new colloidal preparations.

Mr. BISHOP HARMAN also read a paper on

False Hay Fever.

He said it was not often that cases of hay fever came the way of the ophthalmic surgeon, they were almost wholly the monopoly of the surgeon who specialised on the respiratory tract and not a few were gold-mines to the quack. He did not propose any new and infallible panacea for the hardy annual of hay fever—the title of his paper clearly told that. He had observed several cases which had been diagnosed and treated as hay fever and which he had been able to relieve by a very simple procedure, just the relief of the exaggeration of an ordinary physiological reflex. Notes of one case would suffice. A woman, aged 30 years, born and bred in the Midlands, of high intelligence and engaged in responsible work, moved to a southern seaside resort well known for its pine woods. Until this time she had enjoyed excellent health and suffered no other than occasional simple "colds." The spring following her removal she had violent and recurrent attacks of coryza lasting ten days; next spring the attacks lasted a month and on the third year they increased in severity and lasted two months. Her physician diagnosed "hay" or "pine fever" but treatment, even the use of adrenalin, did no more than temporarily allay the severity of the attacks. The patient allowed that nearness to hay or pines did not annoy her but that bright sunlight was distressing, especially to the right eye; relief was best obtained by shutting herself in a room with the windows shut and darkened. Mr. Bishop Harman had the advantage of having seen most of the members of her family; all had astigmatic eyes. The suggestion that her eyes might be at fault was flouted. Later Mr. Bishop Harman examined her. The nose and the throat were healthy but the vision was defective. R.V. = $\frac{6}{18}$, with + 3 D. sphere and − 2 D. cyl. ax. 15 ϕ = $\frac{6}{6}$. L.V. = $\frac{6}{9}$ nearly, with + 0 75 D. sphere and 1 D. cyl. ax. θ = $\frac{6}{5}$. It was now three years since these glasses were ordered and there had been no renewal of the attacks during this period, yet no other treatment than the wearing of the glasses had been attempted. The rationale of these cases of "false hay fever" was perfectly easy of comprehension. Reflex irritation of the fifth cranial nerve area from irregular stimulation of the optic nerve formed one of the stock illustrations of "reflexes" in every text-book of physiology. Sneezing was readily excited by sudden exposure to bright sunlight. In these cases the irritating effects of brilliant light were exaggerated by an error of refraction, particularly by an anisometropia. Experimentally Mr. Bishop Harman was able to produce attacks not unlike those described by the wearing of incorrect spectacle lenses. "Cures" for "hay fever" had gained such an ill reputation, chiefly though an ill-regulated empiricism, and the cure of all ills by "spectacles" had recently been so vigorously exploited, that he almost hesitated to join these two—hay fever and spectacles—in matrimony. But the association of retinal reflexes with fifth cranial nerve irritation was so certain that he thought he might be pardoned if he asserted that the physician who failed to submit the eyes of a sufferer from "hay fever" to expert examination had not only not exhausted all the possibilities of treatment but failed to exclude one of the first causes of trigeminal irritation.

Mr. DEVEREUX MARSHALL asked, If such cases occurred in the spring from light reflexes, why did they not also occur in August and September when the sunshine was as bright?

Dr. BRONNER suggested that the cases which Mr. Bishop Harman had described were what was known as "vaso-motor rhinitis," chiefly found in neurotic women, and which best reacted to general treatment.

The PRESIDENT of the section said that he did not believe in the reflex from the retina, so that unless evidence could be brought to prove that the case was weak.

Mr. BISHOP HARMAN, in reply, said that the cases were most frequent in the spring, for then by contrast the sunlight was most irritating; later, usage and the greater protection of trees reduced the stimulus. The cases were very aptly described "vaso-motor" by Dr. Bronner, that was just what he meant by a reflex effect. As to the President's objection to his use of a retinal reflex to explain the sneezing he thought that all physiologists were agreed on that point and the existence of retinal reflexes was demonstrated by the mobility of the pupil.

Professor HESS (Würzburg) demonstrated by a series of beautiful drawings the

Pigmentary Migration in the Retinæ of Cephalopods under the Influence of Light.

He had found in these eyes the presence of visual purple, a fact not admitted until now of any invertebrate. He proved longer if delivered naturally without removal of the uterus, Professor Wertheim's cases showed that perhaps the abdominal operation would in the future turn out to be the proper operation. He thought that, if possible, the uterus should be allowed to dilate. There were disadvantages of this, however, such as rupture of the uterus. After the puerperium, in which he had seen a cancer become much smaller, perhaps Professor Wertheim's operation could then be more safely and more radically done.

Dr. Wilson replied and said that the cancer might advance during the puerperium.

The President of the section said that his experience was that the cancer retrogressed during the puerperium.

Dr. Campbell then read a paper entitled—

The Influence of the Presence of Pus in the Female Urethra on the Progress of Gynæcological and Obstetrical Cases.

He said that the general practitioner should realize how prevalent pus in the urethra was, both among gynæcological and parturient patients; how frequently that pus contained virulent septic micro-organisms; and how readily it might be the cause of chronic gynæcological ailments and of puerperal septic conditions. In 544 consecutive cases examined in private practice 135 had pus in the urethra or in Skene's glands—i.e., 24·7 per cent. In 372 consecutively examined in hospital practice 135, or 36·2 per cent., had pus in the urethra or Skene's glands. The result of this examination was that in the total 916 cases 29·4 per cent. had pus in the urethra or Skene's glands. In 120 labour cases examined specially for him by Dr. John McLiesh, 18 of them, or 15 per cent, had pus in the urethra and Skene's glands. In 100 cases of pus in the urethra or Skene's glands Dr. T. Carnwath had found staphylococcus pyogenes albus in 96 per cent., streptococci in 6 per cent., and gonococci in 2 per cent. Many of the cases showed mixed infections—a patient with pus in her urethra was practically in the position of a woman with a septic sinus discharging into her vagina and required special precautions during her confinement.

Dr. Wilson said that he had for years attended to, and thought very deeply on, the question of the clinical significance of the presence of pus in the female urethra. He considered that the clinical explanation was the same as that in the case of the male gleet. He was of opinion that experts should be more often on the look-out for pus in this connexion.

Dr. Boxall said that at the General Lying-in Hospital, York-road, London, these cases did not occur, but at the Queen's Charlotte's Hospital in London, where every case was not treated as possibly septic and mercurial douches were not used before delivery, perhaps that was the reason why septic gonorrhœal cases sometimes arose. This was the explanation which he gave when asked by the staff of Queen Charlotte's Hospital to explain the absence at York-road of septic cases which occasionally arose at the Queen Charlotte's Hospital. Those cases were perhaps cases with pus in the female urethra.

Dr. Corby read the account of a case entitled,

Case of Fibroid of the Ovary from a Hermaphrodite,

with photographs, which was very interesting and instructive.

OPHTHALMOLOGY.

Wednesday, July 26th.

Mr. George A. Berry (Edinburgh), the President of the section, after welcoming the members, said: Fifty years ago such rapid strides were made in the science of ophthalmology and in ocular therapeutics that every year brought its record of important discoveries in diagnosis, of new methods of examination, of far-reaching generalisations, often of real advances in ophthalmic surgery. At that time, indeed, a few years sufficed to revolutionise the whole science of this department of medicine until ophthalmology attained to a degree of perfection which led von Helmholtz to say of it that it was "the most strictly scientific department of medicine, the one which most nearly approached to the exact sciences." That ophthalmology can hardly with the same justice be said to occupy so prominent a position at the present day is due to the rapid advances which have been made more recently in other departments of surgery. Some few advances in our special science are, no doubt, of comparatively recent date—e.g., the introduction of antiseptic and aseptic measures in connexion with injuries and operations; the use of cocaine as a local anæsthetic; the appreciation of the rôle played by microbes and the toxins which they engender in connexion with various inflammations of the eye; some few points in pathology, notably with reference to tuberculous manifestations; the use of the electro-magnet for the removal of particles of iron and steel, and the application of the Roentgen rays for their detection and localisation. From the therapeutic point of view, however, there has been but little advance to record; whilst our knowledge of the connexion between diseases of the eye and diseases of other parts of the body is hardly less crude than it was 50 years ago, except perhaps as regards ocular manifestations in certain nerve disorders. Latterly, indeed, instead of leading the way the ophthalmic surgeon has mostly had to follow and to adapt to the requirements of his own specialty the advances, so far as they are at all applicable, which have extended the sphere of general surgery. This comparatively slow advance of recent years is not due to there being nothing left to find out. It is not due to the interest in the special subject of ophthalmology being, for the time, diverted to branches which seem to offer more scope for research. There is at least no dearth of writings on special ophthalmological topics. It is not due to the absence of experimentation with new therapeutic agents; new drugs are constantly appearing which, if they do not succeed in doing a tithe of what is claimed for them, at least raise hopes for the time being. Not a few books devoted exclusively to the consideration of new remedies have appeared quite recently. Even in connexion with diseases of the eye, however, for which it should be possible to estimate the results of treatment, in many cases at least, more fully than for other less accessible organs, there is so often shown the same absence of critical insight into the difficulties of such investigation which seems to characterise the majority of writers on therapeutics. Notwithstanding discoveries in pathology, we make, it must be admitted, but slow progress in treatment. The problems which for us await solution are in point of fact numerous enough but they are for the most part such as seem only likely to be solved when our knowledge of general pathology and medicine has reached a stage or two further than it has at present. We do not even know yet what it is that determines the selection of certain organs and tissues for the manifestation of certain definite pathological processes. We are consequently and necessarily empirics as regards the manner in which we may try to supplement purely local by more general means of treatment. But if we cannot to-day check the progress of an optic atrophy or treat on anything but empirical lines a choroiditis, if we cannot prevent the development of a detached retina, if we cannot even cure a conjunctivitis, we may surely hope that some day it will be possible to do all these things and more. If our progress is slow it is none the less real. We need to be critical, even sceptical, in view of the flood of literature from which we must separate the chaff from the wheat. But we can afford to be, we have reason to be, optimistic as to the future. My own predilections have always been for surgery. There is so much pleasurable interest to be got from watching the effect of surgical interference of any kind, so little satisfaction in cases which reliance has to be placed on medical treatment alone, that we are prone to forget that the laborious, patient investigations of recent times may, in the perhaps not distant future, turn the tables on surgery. We may some day have to admit that many conditions, for which surgical measures seem the only suitable ones at present, will allow of rational successful treatment on medical lines alone. Much of our treatment at the present time may even in the light of future knowledge be of a nature which, if it were then adopted, would be little less than criminal. The present discussions might not perhaps lead to much, yet they sometimes help to lift us out of the groove of self-satisfaction and to correct a tendency inherent in man to think that the only "sensible" men are those who hold the same views as ourselves.

Dr. Adolph Bronner (Bradford) read notes of

A Case of Slight Myopia

in which distressing local and general symptoms were relieved by the use of glasses which were much too strong. He said that recently much attention had been drawn to the use of correcting glasses for the relief of obscure nervous symptoms. In America "heterophoria" and in this country only ones he had to go on in which tuberculous inoculation experiments made the diagnosis of the cases certain, and in these after the lapse of four years the so-called "obsolescent" changes could be seen. The changes were not in the macular region but started near the disc, as most of the 20 cases detailed also did. The absence of much scarring and absence of pigmentation seemed to distinguish the cases from the syphilitic type.

On the utility of tuberculin injections, either for diagnosis or with a view to treatment, Professor Hess said he had injected the old preparations 18 times and the new "T.R." eight times, for diagnostic purposes only. In half the cases he obtained a general reaction but in only two—cases of iritis—was there a local reaction. He only considered a local reaction exact proof of the nature of the inflammation, yet the fact that the general reactions in these two cases were similar to the reaction obtained in the other cases lent an air of probability to there being ocular tuberculosis in these also.

Dr. J. Hern (Darlington) had used the injection in six cases, using only the new "T.R." He thought it a valuable aid to diagnosis but not for treatment. A good reaction certified the presence of tubercle in the body, but its absence was not a sure contra-indication.

On the danger of excising tuberculous eyes Dr. J. Tatham Thompson (Cardiff) said he excised such an eye once for the relief of severe pain but death from meningitis ensued in a few weeks.

Mr. Jessop had operated on two cases and in each fatal meningitis followed in three weeks.

Professor Hess thought it well to wait as long as possible, not only because of the risk of general infection but because, as Mr. Jessop had shown, even very severe cases made fair recoveries in time.

Dr. Shaw said he had seen one case of apparently primary tubercle of the eye in a boy, aged nine years. The growth appeared on the iris of the left eye and increased so rapidly that the eye was excised. Before enucleation some retinitis was seen in the right eye. A month after the operation signs of meningitis appeared but subsided. During the next two years the boy suffered from tuberculous abscesses and bone affections on the left side of the arm and the leg. Pathological examination of the enucleated eye showed typical tuberculous growth.

Mr. J. Herbert Parsons (London) said that the trend of opinion amongst many continental observers was that a real primary onset of the disease did occur in the eye.

Mr. W. M. Beaumont (Bath) cited the case of a girl, aged ten years, under his care where an apparently simple phlyctenular affection of the cornea relapsed, became chronic, was succeeded by iritis in one eye and retinitis in the other, and last of all by a typically tuberculous affection of the cervical glands. It appeared very likely that this was a case of true primary disease of the eye.

On the point raised by Mr. Jessop—the frequency of choroidal infection in chronic surgical and medical tuberculous disease—Sir Victor Horsley (London) said it was a point of considerable importance if chronic tubercle could be determined by examination of the fundus. Was it possible that the appearances of the fundus in tuberculous disease could be distinguished from the appearances presented in cerebral tumour?

Professor Hess said that such a differentiation was not possible by the aid of inspection alone but with the aid of tuberculin it might be. In a case of the kind the injection of tuberculin was followed by a local reaction and by the exaggeration of inflammatory changes about the original disease, and this was considered evidence of the tuberculous character of the original process.

Mr. Herbert Parsons raised the question as to the greater liability to permanent pigmentary changes in tuberculous affections as compared with the effects of congenital syphilis. Mr. Jessop had expressed his opinion that pigmentation was rare after tuberculous disease.

Mr. Bishop Harman said that from his experience of the blind and partially blind children in London County Council schools, he was distinctly inclined to think that pigmentation was much more associated with choroiditis the result of congenital syphilis than with any other disease of children. He based this opinion on the case with which a series could be found from the least degree of pigmentation to the grossest, and associated in many cases with the typical stigmata of congenital syphilis.

Mr. Jessop replied, agreeing as to the dangers of setting up general tuberculosis by excising an affected eye and emphasising the danger to the body generally when the sclera was affected.

Dr. Hern read a paper entitled

Some Observations on the Effect of the Presence of Adenoids in the Naso-pharynx on some Affections of the Eyes.

Soon after Meyer of Copenhagen read his paper before the International Medical Congress in London in 1881 and the facial and other indications of adenoids became familiar, he noticed that cases of phlyctenular, eczematous, or scrofulous conjunctivitis or ophthalmia frequently presented the adenoid facies; and that unless the throat condition was treated satisfactorily the treatment of the eye conditions was most unsatisfactory. These observations referred in the main to children but similar eye affections were found in adults associated with rhinitis and hypertrophied turbinal bones. He did not think that the association pointed to a common strumous or tuberculous origin for these conditions; many cases showed no such family taint. Some, it is true, did ultimately succumb to tubercle, but he thought the conditions he had mentioned favoured this ending only in so far as they induced debility by continued irritation and by preventing respiration. And similarly he thought that the eye conditions were indications of the onset of this debility arising from these same causes.

Mr. A. H. Benson (Dublin) read a paper on

The Evolution of the Operation of Blepharoplasty.

The operation was for the relief of entropion consequent on neglect of trachoma. Very many operations had been devised, a few were satisfactory, and more were injurious. He did not intend to introduce any new operation but to trace the stages whereby they had arrived at a procedure which in their hands in Dublin had been satisfactorily followed for 20 years. The first attempt at remedying the hurt of entropion was both drastic and disastrous; the surgeon removed with scissors the lid margin with all its accessories, permanent shortening of the lid with exposure of the eye followed, and xerophthalmia was grievously common. Next the follicles of the offending cilia were removed and the other marginal structures spared: this was a step in the right direction. Later efforts were directed to saving the cilia either by cutting into the deformed tarsus, straightening the lid and allowing the gap to granulate up, or else by the removal of part of the skin of the lid so as to drag up the displaced cilia; these procedures both involved loss of substance and so were defective. Next succeeded transplantation of the hairs and replacement by a strip of skin, with the resulting disadvantage that the downy hair of the skin was brought into apposition with the cornea and produced a new and no less chronic irritation. Their present method was to incise the whole length of the margin of the lid behind the line of cilia to the depth of a quarter of an inch and to place in the gap formed between the front and back layer of the lid a strip of mucous membrane excised from the lip The procedure was at once simple and rapid of execution and the most trustworthy in its final effects—in fact, it cured the entropion.

Professor Hess, Dr. R. W. W. Henry (Leicester), and Dr. Tatham Thompson agreed that the method advocated so eloquently by Mr. Benson was all that he claimed for it; they had used it for long periods.

The President of the section remarked that the only true test of such operations was that of time; they must strive for the most permanent relief possible.

Mr. Benson considered that experience proved that if the method he advocated showed a good result a fortnight after its performance the good result would be permanent.

Dr. Shaw said that he had often seen his predecessor, the late Dr. W. A. McKeown, transplant skin from behind the ear with much success.

Mr. J. B. Lawford (London) agreed in the excellence of the operation but considered that there were some gross cases of malformation which could not be met by it.

The President of the section showed a

New Vision Test,

with which he had been experimenting for some time, for the detection of fine differences in visual acuity. On a large disc were mounted a series of smaller discs; these were printed in chequers of black and white squares. The squares were in such gradations of sizes that they subtended the same angles as the different sized letters in Snellen's types.

that all cephalopods studied by him showed this pigmentary migration within the retina, but the rapidity of the migration differed in various species, and it was different in different parts of the same retina, especially in the small horizontal stripe which contained very long and small rods, and corresponded evidently to a stripe of best vision. He also related some experiments on the same subject performed on monkeys' eyes.

Dr. F. W. EDRIDGE-GREEN (London) expressed his pleasure at the findings of Professor Hess's work. He had added to the list of those creatures possessing visual purple another group which at one time were confidently asserted to be devoid of it; the same had been recently proved for the common bat.

Dr. KARL A. GROSSMANN (Liverpool) read notes of a case of

Congenital Absence of the Dilatator Muscle of the Pupil.

A girl, five years of age, of normal general physique, was noted to present markedly eccentric pupils. They were placed upwards and inwards, were of oval shape, and were slightly ragged in the margin. The surface of the iris showed a number of coarse parallel folds. The whole iris was tremulous on quick movements of the globe and the lens was found to be absent or represented only by an opaque mass in the vitreous. Instillation of eserine demonstrated the presence of a sphincter muscle by contraction but atropine affected the pupil little if at all. The condition, he thought, illustrated the interdependence of the development of lens and dilator muscle.

Dr. GROSSMANN showed a small form of

Hollander's Modification of Paquelin's Cautery

which he used in conical cornea. Through the platinum end of the instrument there was fitted a fine platinum worm-like tube; through this was pumped air which was raised to so high a temperature that it formed a most efficient and delicate drying application to these thin and bulged corneæ.

Dr. GROSSMANN further showed numerous and very fine lantern colour photography transparencies of cases of Lepra Ophthalmica which he had examined in Iceland.

Dr. CECIL E. SHAW (Belfast) read notes on a case of

Toxic Amblyopia following Influenza.

A man, aged 20 years, of good history, suffered from a mild attack of influenza in February last. A week later the vision was affected and when seen fingers could only be counted with the right eye at one foot, and there was no perception of light in the left eye. The pupils were dilated but the fundus was normal in each eye. The sense of smell was temporarily lost. By the second week vision was further diminished and there was numbness in the right arm, leg, and side, and walking was difficult. Paresis also appeared in the left internal rectus with a divergent squint. In March there was a slight improvement which increased until in June he was healthy again in body but the vision remained defective—right vision being only $\frac{1}{24}$ and left vision [illegible]. There were no changes in the fundus.

Mr. BISHOP HARMAN said that he had two cases under observation of somewhat similar nature. Both were schoolboys of healthy physique and family. One recovered from an attack of influenza with permanent loss of central vision which necessitated his being trained in a blind school. The other was seen and put to bed at the very outset of the attack; there was a marked degree of choke-disc and vision was lost but in the course of a month vision recovered to $\frac{6}{6}$ in one eye and $\frac{6}{9}$ partly in the other.

THURSDAY, JULY 27TH.

Mr. W. H. H. JESSOP (London) opened a discussion on

Intra-ocular Tuberculosis.

He limited the subject to disease of the interior of the eyeball and therefore included cases affecting the choroid, iris, ciliary body, and retina; the chief part was devoted to the choroid—including miliary tubercle of the choroid and solitary choroidal tubercle. Of solitary choroidal tubercle an analytical table of 20 cases was given collected from various authors. Statistics were collected as to patients' sex, age, previous history, family history, clinical tuberculous signs in other organs, operation, results, and macroscopic and microscopic examination. A solitary tubercle was found generally as a rounded spherical body of grey, white, yellowish and different coloured greys starting from near the optic disc and was subretinal, seldom tending to infiltrate the retina, the retinal vessels lying clearly over it. There were generally nodules to be seen on it and often it seemed made up of nodules. The retina around might be flecked with spots like diabetic retinitis but not pigmented; the tumour was subretinal for a very long time. Yellowish spots might be seen on the surface of the tumour like lichen and were caseation changes. Hæmorrhages might occur but were not often recorded. In miliary tuberculous choroiditis tuberculous meningitis was nearly always present. At St. Bartholomew's Hospital, in 15 cases of tubercle of the choroid found in the post-mortem room 14 had tuberculous meningitis and only one had not. This case had miliary tubercle of the lungs, the peritoneum, the kidneys, the spleen, &c. He was sure that the two very frequently coexisted and it was not a fact, as stated by Horner, that the presence of tubercles in the pia mater contra-indicated their presence in the choroid. Tubercle of the iris and ciliary body were next treated of and also the rare condition of tubercle of the retina. As to diagnosis in tuberculous cases the greatest test was certainly inoculation experiments. In many cases, especially when caseation had taken place, the bacillus was not to be found. Giant cells, tuberculous stroma, endothelial cells, and caseation were all of minor importance in diagnosis. Other signs of tubercle in the body helped the diagnosis. In order to limit the discussion the following questions to be answered were suggested as the basis of discussion: 1. The relative frequency of primary intra-ocular tuberculosis. 2. How often was choroiditis met with in acute miliary tuberculosis? 3. What was the value of tuberculin—(*a*) as an aid to diagnosis; and (*b*) as treatment? 4. What was the danger of dissemination as a result of excision in intra-ocular tuberculosis? 5. In tuberculous affection limited to the choroid was there little tendency to pigmentation or scarring of the retina or choroid and were vitreous opacities seldom present? 6. How often in chronic tuberculosis, especially pulmonary, were there choroidal lesions? 7. In chronic choroidal tubercle what were the signs of "obsolescent tubercle"? On these points his own opinion was as follows: 1. He had never come across a case which he could prove to be primary intra-ocular tuberculosis and doubted whether such a condition ever existed. 2. From statistics the percentages varied greatly but probably it was to be found in about 50 per cent. post mortem and in from 30 to 35 per cent. by the ophthalmoscope before death. 3. In his own practice he had personally had little experience but was certain that the old tuberculin was not trustworthy and often did much harm. From the excellent results of von Hippel and Schieck in tuberculin T.R. he should certainly try it on every doubtful case as a means of diagnosis and in every case as to treatment. It was necessary to watch very carefully the temperature of the patient, which should be taken night and morning. The largest dose at start ought not to be greater than $\frac{1}{500}$th milligramme, gradually increased to one milligramme dose. 4. Excision in intra-orbital tuberculous condition of the eye should, in his opinion, be seldom done unless there was a great deal of pain or the condition was actually telling on the patient's health. As the condition was not primary it only removed one focus of the disease and the experiences set forth by Rogman seemed conclusive as to the danger. This was apparently much increased if the sclerotic was involved. Out of 11 cases of death after excising a tuberculous eye no less than eight died within two months from tuberculous meningitis, a great contrast to Schieck's 13 cases treated with tuberculin in which all were cured and no eye was lost. 5. In miliary tubercle of the choroid he had never seen vitreous opacities, neither were they present in his two cases of chronic choroidal tubercle. In these two cases also, which were the only ones he knew certainly cured, after severe tuberculous choroidal trouble the chief characteristic was the little apparent change in the part of the fundus in which the tubercle existed; in another case the absence of any pathological pigmentation and in a further case the slight amount of pigmentation even in the neighbourhood of the greatest lesion were striking 6 In cases at St. Bartholomew's Hospital of chronic pulmonary tuberculosis he could find no note of chronic choroidal change. Dr. George Carpenter and Mrs. Stephenson found in 119 cases of chronic tuberculosis in children choroidal changes in 11, or 9·24 per cent. These authors arranged them into four groups; (1) solitary; (2) multiple; (3) disseminated; and (4) diffused. 7. As to this point his own two cases were the transmitted as intrinsic pathogenic variations of the embryonic brain and nervous system; such was the variety of delusional insanity founded upon definitely evolved hallucinations, also certain affective deep-seated insanities of the depressive and suicidal type. Some insanities owed little to heredity and much to stress (anxiety, shock, and great calamities). The cure of pulmonary tuberculosis would go a long way to diminish the lower forms of insanity—especially idiocy, imbecility, and feeble-mindedness.

Mr. EVAN POWELL (Nottingham) expressed gratitude for the splendid collection of valuable statistical material by the President of the section and hoped that other members would engage in similar investigation and "go and do likewise."

Dr. SCHOFIELD read a paper on

The Extension of Psychology in Medicine,

not, he said, as synonymous merely with the psychology of insanity but as embracing the field of psychological conditions observed in other diseases and in normal life. He spoke of the educational value of training in psychology, not the metaphysical speculative theories of armchair philosophers but the scientific structure of knowledge built up by observation, experiment, and induction in both normal and pathological human subjects. He also laid down certain statements as to the nature and relations of conscious, subconscious, and unconscious mind, using the last term in a wide sense to cover various phenomena of the life of the nervous system, not necessarily psychical but dependent on so low a level as the bulbo-spinal system.

The PRESIDENT of the section made some observations on the value of a knowledge of psychological medicine and urged that it should enter into the curriculum of the medical student, for every general practitioner and physician had occasionally to meet and to treat, at least temporarily, such cases on emergency and until a specialist could be consulted.

Mr. JAMES STEWART (Clifton) referred to the psychic action of drugs which was, he believed, generally neglected by those who prescribed them.

The discussion then terminated with a proposition drawn up by the PRESIDENT of the section, moved by Dr. HYSLOP and duly seconded, and unanimously passed, to the effect that the central council of the British Medical Association should be asked to appoint a committee for the investigation of hereditary forms of disease and to place at the disposal of the committee such funds as would enable it to report on the whole subject.

THURSDAY, JULY 27TH.

Mr. R. C. STEWART (Leicester) read a paper entitled

Short Notes on Lunacy in Leicester, showing Plans of the New County Asylum.

He dealt with the historical development of lunacy in Leicester, the erection of the asylum, and its administration under succeeding superintendents. Various improvements were made in the internal arrangements of the buildings as regards ventilation, flooring, and general hygienic condition until in the last decade the Leicester County Asylum was universally recognised as one of the best equipped and administered public institutions for the care and treatment of the insane in the Midlands. Referring to the problem of increasing admissions, Mr. Stewart said that the asylum was now very slightly overcrowded and consequently that only patients belonging to the county of Leicester could be admitted. The increased pressure on accommodation in recent years led to the adoption by the Leicester asylums committee of a plan of building a new asylum. The complete plans have already been prepared and the building is now in process of erection. Mr. Stewart showed on a large scale plan a number of interesting features in the disposition and arrangements of the wards and dormitories to secure for the patients free and ready access to the gardens and walks and described the addition of two houses to accommodate private patients paying one guinea weekly, detached from the main buildings and having almost the home-like appearance of villa residences which, he thought, would be appreciated by the patients.

Dr. JONES and Dr. BOWER made appreciative comments on some of the technical particulars of construction of the new asylum.

Mr. STEWART, in reply, said that the flooring adopted was a hard and almost imperishable structure of teak wood specially prepared for the purpose.

Dr. HYSLOP opened a discussion on

Occupation and Environment as Causative Factors of Insanity.

In dealing with the causation of the insanities, he said, "we must always take into account and allow for factors which are internal—*i.e.*, either due to inheritance or the existence of some fundamental capacity which cannot be explained as the result of ancestral inheritance." It was also necessary to form clear conceptions as to the operation of sociological factors or, in other words, to the social environment and those which had their origin in physical causes either affecting the physical organism or having their seat in the physical mechanism itself. Regarding the British race they saw a remarkable transformation which had taken place. The race had passed from a natural state to an artificial one of enforced brain activity with all its attendant evils. The effects of rural and urban life had never been accurately determined. The transformation from rural to urban life was accompanied by influences which proved deleterious to mental health and stability. Migration from country to town not only brought about a condition of nervous strain for those who migrated but also left its stamp upon the depopulated rural districts in the form of degeneracy owing to intermarriage among relatives and the residuum of the less fit. Education and agricultural depression have favoured this tendency to migrate and they have also largely aided in changing the social conditions of those who by habit and heritage were ill-adapted for the expenditure of nervous energy. Whereas education and the requirements of this brain-age necessitated a constant increase in the output of nervous and mental energy so as to enable the greater number to reach the highest possible standard, the output of physical energy was undergoing a constant diminution owing to the "standardisation" of labour at a very low quantity, be it skilled or otherwise. They were confronted, therefore, with the problem of over-education and the possibility of a faulty expenditure of nerve energy, the problem of diminution of hours, and the various restraints imposed by trade unionism, not to mention other agencies which as a whole aided the tendency to standardise at the level of the least efficient and thereby to diminish the vitality of the British unit. Education wisely directed was not in itself an evil, but ever since the Education Act of 1870 they had been striving with faulty methods after the unattainable. With the increase in the imposition of every grade of education from the Board school to the highest university curriculum, the brain tax on the people had become more and more irksome and the amount of pauperism, overcrowding, and mental failure had increased by leaps and bounds far beyond anything before known in the history of the empire. The public mind was at present much agitated by the alleged prevalence of physical deterioration, by the diminishing birth-rate of the last few years, and by the increase in infantile mortality. The Bishop of Ripon, speaking in the House of Lords a week ago, gave it as his opinion that the facts revealed in the inter-departmental Commission on Physical Deterioration were pregnant with danger to the empire. He contended that unless some steps were taken the British race would no longer be able to maintain its position as a colonising and a ruling power. While the tendency to degeneracy of mind and physique arose from the modes of life and the unphysiological habits and surroundings of the male population now well understood, the occurrence of a similar downward tendency had been recently recognised in women. The causes of this were interesting. Alcoholic intemperance had, like secret drinking, been increasing among women partly owing to increased facilities of obtaining alcoholic liquors. Pregnancy, parturition, the puerperal state, and other conditions incidental to the female sex became greater sources of danger in the new modes of life and women were less fitted than men to withstand the strains upon their nervous systems. In a word, the removal of woman from her natural sphere of domesticity to that of mental struggle and fierce competition in the strenuous life had not only rendered her a physically feebler mother less fit to sustain the virility of the race but it had induced in her a tendency prone to issue in the increasing degeneracy of her progeny. Woman's rôle in this world was that of wife and mother. They granted to woman the right of being a great civilising and refining agent as well as being an ornament, but in intending her to be a mother nature gradually fashioned her destiny for woman in the æons of the past. And although much had been, and was being, done to improve the fitness

In practice it was his habit to ascertain the smallest disc of chequers which could be distinguished as such at a given distance. By way of control grey discs were intermingled with the chequered discs. By altering the positions of the lines of the chequers it was possible to ascertain the axis of an astigmatism very readily and he found that children would more readily respond to this mode of subjective test of visual acuity than when Snellen's "E" test was employed.

Mr. **BEAUMONT** said that the test seemed to meet some of the difficulties found in using the ordinary test types.

PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 26TH.

The Presidential Address was delivered by Dr. **ALEXANDER R. URQUHART**, medical superintendent of Murray's Royal Asylum, Scotland, on

The Clinical Study of the Heredity of Insanity.

The proper adjustment of organism to environment was, he remarked, a necessity whereby only life could be lived and progress made possible. Statistical facts and data were, when carefully collected, the foundation of nearly all their knowledge of heredity. This was the Galtonian method, now developed in the special direction of "biometric" study by various investigators. The breeding of animals, the culture of plants, and man's own experience of health and disease in families constituted a body of knowledge extending for centuries into the past and at present classified and collated by various workers, so that it had added largely to the scientific knowledge of heredity. The special heredity of mental disease had been paid attention to in the classical work of Morel of Belgium (1858) and Thurnam of York about the same period. Since then memoirs had been published by Dr. Grainger Stewart (1876), Dr. G. H. Savage (1877), Dr. W. F. Farquharson of the Westmorland Asylum (1893), and by many French and German alienists. The figures given by various authorities as to the prevalence of heredity as a factor in insanity were in fair accord, the observations made showing that from 45 to 50 per cent. of all cases of insanity were of predominantly hereditary origin. This was a conservative estimate, for some authors had traced a hereditary origin in 60 per cent. or more of cases admitted to the asylums of large cities. Various psychoses, apart from, and not amounting to, insanity, were met with in abundance in the families of the patients, whether among the parents, uncles and aunts, or among the brothers and sisters. Dr. Urquhart showed a large number of coloured diagrams in which, in the form of genealogical tables, these facts relating to insanity on the one hand and the various family neuroses and psychoses on the other were graphically demonstrated. A tuberculous ancestry was, he said, fairly common in insanity, especially in cases of idiocy, imbecility, and the feeble-minded forms of the "degenerative" insanities. The heredity of syphilis was hard to discover and difficult to trace. A drug-craving heredity, as, for example, morphinism or cocainism of the parents, was rarely found. A cancerous heredity, in the absence of neuroses and psychoses, was definitely traced in a moderately small number of cases. As the result of 25 years' observation on 1104 cases admitted to the asylum it was found that hereditary predisposition in the line of ancestry was very marked in nearly 50 per cent and that a large proportion—about 70 per cent.—had insane relatives not in the direct line of the patient but collaterally related to him closely (brothers and sisters, or uncles and aunts paternal or maternal), while the patient's own parents manifested no insanity themselves. If neurotic ancestors and near relatives were counted in the etiology as contributory proof of hereditary taint the total heredity of insanity in round numbers would mount to about 75 per cent. Studying the families of 623 certified patients it was found that insane parents or near relatives existed to the total of 702 in the 623 families; it was further ascertained that the neurotics numbered 240, the paralytics 191, the alcoholics 169, the tuberculous 259, and the cancerous 70 in the total number of the families. A large series of over 100 tables of data was exhibited and the whole body of facts was expounded with their aid. Dr. Urquhart urged, in conclusion, that in the study of the ancestral heredity of the insanities particular attention should be paid to the occurrence in the ancestory or close collaterals of the presence of psychoses, neuroses, alcoholic and drug habits, apoplexy, senile dementia, congenital mal-development with great eccentricity of mind, suicidal impulses, and the presence of the two great constitutional degeneracies, tuberculosis and cancer. The statistics of general hospitals constituted only a part, a small part, of the data required for a due investigation and study of heredity. Science, the high aim of which it was to search, to investigate, and to understand nature and thus to obtain the mastery of nature, should start with the belief that nature was intelligible, comprehensible, and to some extent conquerable. The time was approaching when, with the coöperation of pathology, clinical medicine, and comparative biology in the widest sense, a fuller light would be achieved regarding many of the mysteries of heredity.

Dr. T. B. **HYSLOP** (Bethlem Royal Hospital) said that the mental and physical health of the community was of the utmost importance, and judging from the trend of enlightened public opinion there was immediate need for legislation in matters pertaining to insanity. The large annual increase of insanity and the alleged prevalence of physical deterioration showed that there was retrogression in a large section of our race. There was need for a competent commission to inquire into the matter; the Commissioners in Lunacy were too much overburdened with work to be of any service in this respect. A thorough and systematic inquiry, of which the presidential address embodied the best features, was necessary. Dr. Hyslop also spoke on the subordinate rôle which toxins played in insanity, not as primary causes but frequently as "terminal infection" of the damaged body.

Dr. W. **LLOYD ANDRIEZEN** (London) referred to the biological aspects of heredity and variation, and stated that the higher animals and man showed more stability than the lower forms (protozoa and lower metazoa). Mutation, as described by Darwin, De Vries, and others, played a very important rôle in modifying heredity, and he spoke of recent researches in biology and mental pathology which showed that pathogenic mutations might occur in families of the human race and lead to three or four generations of cerebral and mental degeneration ending in extinction of the stock in question. Regression, as defined by Galton, affected only normal and small variations and kept them within conservative limits but pathogenic mutations ended in extinction of the stock in a few generations by its prepotency. So it was in many prepotent cases of tuberculosis, the insane diathesis, and cancer. He referred to the classical work of "The Jukes," by Dugdale, and to the continued production of demi-cretinism and sterile cretinism in parts of the world as classical instances of pathogenic mutation. Imbeciles, feeble-minded and defective children, anergic tramps, vagrants, and prostitutes were products of degeneracy brought about in various ways by the coöperation of bad parentage and evil environment, a grievous burden to the State, whose serious attention should be awakened from its long slumbers.

Dr. **FLETCHER BEACH** (London) referred to the tuberculous factor in the parentage which entered largely into the etiology of idiocy and imbecility as shown by the constant experience at Darenth Asylum, the Bicêtre, and other special institutions for idiots and imbeciles. As regarded the heredity of insanity proper—viz., the higher degenerative and the more purely psychic alienations—his experience agreed with that of Dr. Urquhart. He strongly hoped that the Government would take up the investigation of the matter.

Dr. A. M. **JACKSON** (Nottingham) spoke of the importance of studying the character, not only of the brain as such, but of its vascular condition in cases of hereditary insanity.

Dr. A. T. **SCHOFIELD** (London) said that there was much ignorance of the public as to insanity and its transmission, while some people exhibited callous indifference when they wished to marry and seldom or never followed the medical advice which they sought "for conscience sake." Disorders of excretion and digestion had an important etiological rôle in the development of insanity.

Dr. T. **JOHNSTONE** (Leeds) remarked that paranoia, a slowly progressive incurable insanity, might develop from eccentricity and that unsuitable marriages might induce hopeless hereditary insanity in the offspring of a tainted father or mother.

Dr. **DAVID BOWER** (Bedford) agreed generally with the facts and conclusions of Dr. Urquhart and spoke of the increase in alcoholic insanity.

Dr. **ROBERT JONES** (Claybury) said that heredity and environment were both important. Some insanities were considered it an undoubted fact that the majority of children born of syphilitic parents possessed a marked immunity to the disease, for when exposed to the specific poison in later life either they acquired the disease in a very mild form or exhibited complete immunity, so that there was a striking tendency for the disease to be self-eliminating in its effects, and he mentioned the fact that he had only once seen a typical secondary rash in a man with the well-marked stigmata of congenital syphilis. Syphilis may therefore act as an eliminator of the unfit but if his premisses were correct it also acted as a causative factor in the production of degenerate stock, as owing to its long duration it tended to devitalise the reproductive elements as well as the body cells. Evidence was available, too, as to the devitalising influence of lead, for not only was chronic plumbism capable of producing abortion and miscarriage in the female but male subjects of the disease mated to normal females were sterile or gave rise to devitalised offspring which either died in utero or shortly after birth. Discussing next the influence of alcohol Dr. Mott referred to the generally accepted view that the poison was a potent factor in the production of mental and physical degeneracy of the offspring and pointed out that no certain data were available to combat the equally valid assumption that the mental defect of control, or what not, that led to the drunkenness in the parent was alone transmitted—increased perhaps owing to the influence of the poison and made permanent by imitation, and stated his opinion that alcohol was an active poison to all neuropathic stocks and so acted as an eliminator as well as a producer of the unfit, and in this connexion he differentiated between fermented alcoholic beverages and distilled liquors. The belief that tuberculosis was particularly prevalent, although preventable, in asylums was combated by evidence obtained by him in two of the London county asylums, which showed that between 40 and 50 per cent. of patients dying therein exhibited obsolescent or active tubercle, in the case of the majority dating back to a period prior to admission. Tubercle must be regarded as an expression of low vital resistance of an enfeebled and degenerate stock rather than a cause of insanity and although the germs of the disease were destructive to the individual they were, on the other hand, conservative to the race by removing the mentally unfit at an early period of adolescence; the probable explanation of the association of tubercle and insanity was to be found in the congenial soil provided by a stock with a neuropathic taint, especially when aggravated by alcohol and sexual excess. Another point relating to the elimination of the unfit was touched upon by Dr. Mott when he stated that the ranks of urban prostitutes were largely recruited from the morally defective and feeble-minded who, generally early in their career infected with the gonococcus, suffered from adhesive inflammation of the oviducts and were thus rendered sterile. He next dwelt upon the comparative value of statistics in relation to the hereditary transmission of nervous and mental diseases as illustrated by figures dealing with the London county asylums admissions for the last ten years. These, he pointed out, were untrustworthy, heredity as an assigned cause of insanity at one of the asylums being recorded as 11·7 per cent. in one year and 27·8 per cent. the next year, and he briefly discussed the factors that tended to make them so, expressing the opinion that the average in which heredity was the assigned cause of insanity is much below the real percentage and that insanity itself is certainly not decreasing but is probably increasing. In conclusion the President of the section queried whether the slow increase of constitutional immunity and the securing of a better social environment for the masses were the only available means for the prevention of social degeneracy, or should some other means be adopted, such as the encouragement of the reproduction of the fit, the more effectual limitation of the reproduction of the unfit, or preventive measures against the spread of alcoholism, syphilis, and tuberculosis?

The results of the work of Dr. GEORGE A. WATSON (London) upon

Inherited Immunity: Experiments with Ricin and Abrin,

were then given by the President of the section in the absence of the author in some detail, from which it appeared that the effect of prolonged immunisation of rabbits and guinea-pigs against abrin and ricin was to diminish reproductive activity in both sexes, without, however, interfering with the sexual appetite; that when offspring resulted, especially when the female was the immunised parent, they were puny, born dead, or died shortly after birth: whilst the reproductive organs showed no changes to account for these facts. No immunity could be shown to be transmitted through the male parent alone but in one experiment the offspring of immunised parents showed considerable immunity, probably gained through the maternal blood and milk.

Dr ARCHDALL REID (Southsea) pointed out that in discussing questions of heredity it was necessary to distinguish between variations and acquirements. When a toxin circulating in parental blood injures the germ cell and so leads to the production of degenerate offspring it does not follow that the injury constitutes a variation—a new character transmitted to the offspring. It may be a mere acquirement and therefore not transmissible. In fact, it is almost certainly an acquirement, otherwise it would be impossible to explain why races which have long been subjected to the influence of such a virulent poison as that of malaria have not become extinct by accumulation of injury. The obvious conclusion to be drawn from this fact of the survival of races long exposed to particular diseases is that the toxins of disease, even when they act directly on the protoplasm, cause not transmitted variations but non-transmissible acquirements.

Mr. CHARLES J BOND (Leicester) continued the discussion by contributing his study

On the Correlation of Sex and Disease.

Instancing first hæmophilia, the best-known example of a disease usually associated in its manifestations with one (the male) sex, although the abnormality was transmitted almost exclusively by the opposite (the female) sex, Mr. Bond pointed out another and equally important form of sex and disease association in which, whilst both sexes were equally liable to a given disease, in some particular family the males were attacked and the females escaped and in another family exactly the opposite took place, and illustrated his remarks by means of a family tree showing the incidence of ichthyosis on the male side and running through three generations. Passing then to deaf-mutism Mr. Bond stated that he had been able to investigate the family history in 12 instances and the important point brought out by his observations was that the abnormality, though affecting both males and females, was mainly limited to one sex in each family. The last family in his series was particularly striking in that the parents being healthy the first three children born of the union were females and healthy: the next six were deaf-mute males; then followed four healthy females: and finally a healthy male. Following this series of families Mr. Bond related a further series of five families in which both sexes were affected, explaining the apparently conflicting evidence by stating that the affected males and females were either twin or successive births or in one family the only two children born. Mr. Bond summarised his results by pointing out the absence of direct transmission of the disease from parents to the children; the marked fertility of the families in which deaf-mutism occurs, Leicester and Derby statistics giving an average of seven children as against an average of five; the affection of only one sex—and not always all the members of that sex—in a family; and in the exceptional cases where both sexes were affected in one family, the deaf-mute children were either twins or successive births. Mr. Bond remarked on the paucity of their knowledge of the factors which controlled the determination of sex and suggested that in the case of deaf-mutism the female or male sex character, as the case might be, in each family had become linked up with another character, in this particular instance an abnormality or disease—namely, deaf-mutism; and from the data he had placed before the section it would appear as though the gametes produced at one period of the life of the parents more nearly resembled each other than those produced at another period, either earlier or later, an assumption strictly in accordance with the results obtained in experimental breeding in animals. Mr Bond concluded by expressing the belief that sufficiently wide investigation would demonstrate the sex correlation of even the infective diseases, such as tuberculosis.

Mr. E. SCHUSTER (Oxford), the Galton Scholar in Eugenics, then read a paper entitled

On the Data required by a Statistician for the Study of Inheritance of Disease,

in which he suggested that the subject of the inheritance of disease was one which required ultimately to be dealt with by the statistician; and although statistical methods were of the female population to become wives and mothers he thought there was a tendency on their part at the present day to depart from their rôle in nature and that the obligations of womanhood and motherhood were becoming through all classes of society more and more neglected. The forcing education and exhausting overstudy of girls in the period of puberty and adolescence rendered them neurotic and was incompatible with perfection of sexual development and vigour, their capacity for child-bearing and child-rearing was stunted, and the artificial conditions of society which demanded that woman should participate in the keen, arduous, and trying intellectual struggles and competitions, hitherto the lot of man alone, had done much to bring about the physical deterioration, the infantile mortality, and the diminished vitality of the progeny—the penalty exacted by nature for the violation of her laws. Modern conditions of life and society failed to recognise, indeed, looked with almost aversion on, the idea hitherto universally recognised that woman did more than half to fashion the destiny of the race, that her obligations began with childhood, culminated in the production and upbringing of children, and only ended when she had nourished her young and imparted to them a vigour and fulness of life which could not be obtained by any artificial modes of feeding so much in vogue at the present day. Men would be better able to support their wives and families if not handicapped by female competition; and by giving up many of the so-called claims of society, excessive personal adornment, or restless desire for amusement, in other words, by being content with a simpler life, woman would make the task of man much easier of accomplishment. It was a miserable travesty of the scheme of evolution that the brains of babies should be State-fed by mental arithmetic while their little bodies were nurtured by artificial foodstuffs derived from every available source other than their own mothers. Dr. Hyslop concluded with observations on the influence of the religious and moral environment on women. Religion and moral obligation overlapped each other considerably and both were the outcome in nature of a deeper lying fundamental law of wisdom and righteousness which revealed itself in the highest evolution of sentient beings, of whom man was the type on this earth of ours. To voice these problems of vital importance and interest to the welfare of the race he thought that the medical faculty should be more strongly (numerically) represented in Parliament.

In the discussion which followed Dr. ROBERT JONES referred to the influence of mental over-pressure in the production of insanity as given in the statistics of insanity in the profession of governesses who showed a higher per centage of insanity than did the class of licensed victuallers and barmaids. This was borne out by the reports of the Commissioners in Lunacy a few years ago published shortly after the last census. He dwelt upon the degeneration occurring in the residual element left by extensive migrations from urban or country districts. He agreed with Dr. Hyslop as to the influence of religion, as he thought everybody would admit the influence of high ideals in enabling persons to preserve mental and physical health. Some of Dr. Hyslop's conclusions he thought indicated a pessimistic view in regard to womankind which he could not share.

Dr. ANDRIEZEN said that failures were inevitable in the progress of evolution of life and of races. A comforting assurance in regard to the hereditary transmission of evil traits was that the "tendency to regression" expounded by Galton showed that full inheritance was the exception and not the rule. Women had by long æons of evolution reached the exalted position of motherhood, revered and honoured by man, and she should never relinquish it.

Dr. SCHOFIELD defended woman ardently against some of Dr. Hyslop's "strictures," as he thought they were. He considered it quite right that women should, if they wished it, enter into the competition of professional life. He would not debar them in such legitimate and praiseworthy aspirations. Religion was an important factor in influencing for good the baser and lower passions of man.

Dr. JOHNSTONE dwelt on the importance of the environment. In this connexion he quoted examples from Virgil, Tennyson, Byron, and others, and said that in the professions of divinity, law, and medicine the advantage lay with the last.

Dr. C. S. MORRISON (Hereford) spoke at some length on the evils of emigration resulting in the degeneration of the residuum left behind unless it was reinforced by fresh blood. Sometimes marked deterioration occurred in such depleted communities.

Dr. FLETCHER BEACH spoke of the great numerical excess of women over men which made the social problem hard and complex in regard to earning a living, for the "superfluous women" could never expect to find husbands. He looked upon teaching as an excellent occupation for women. He believed governesses were prone to insanity owing to the anxious and precarious nature of their profession.

Mr. JAMES STEWART said that women so long as they retained the freshness and attractiveness of youth would not experience difficulty in finding husbands.

Dr. HYSLOP replied.

Dr. W. A. POTTS (Birmingham) read a brief paper on

The Causation of Mental Defects in Children,

dividing the latter into the three classes of idiots, imbeciles, and the feeble-minded. These could again be divided into a "deviational" and a "degenerative" group. "Except the small number classified as deviations from the normal I ascribe practically all cases to physical degeneration at an earlier stage," concluded Dr. Potts.

Brief remarks followed the paper and after Dr. POTTS's reply the meeting terminated.

PATHOLOGY.

WEDNESDAY, JULY 26TH.

Dr. F. W. MOTT, F.R.S. (London), the President of the section, opened the discussion previously arranged for the day with an address entitled

The Relationship of Heredity to Disease.

First promising that the importance of heredity in relation to disease could only be estimated by carefully collected comparative statistics based upon a family history that included grandparents, uncles and aunts, and even first cousins, Dr. Mott referred to the commonplace observation "Like begets like" (which he contended was more correctly rendered by the formula, "Like tends to beget like") as being first met with in the writings of Lucretius, and to the confirmation of this aphorism afforded by the independent observations of Galton and Weismann that each parent contributed one-fourth, each grandparent one-sixteenth, and so on, to the individual offspring. Instances of hereditary transmission of defective durability of special tissues—e.g., hereditary ataxy, or of inherited morphological defects of blastogenic origin—e.g., hæmophilia, polydactylism—afforded excellent examples for the study of hereditary transmission owing to the almost complete elimination of the personal equation of the observer and were illustrated by a series of lantern slides and their chief points of interest were enlarged upon. Inherited tendencies to defective metabolic processes and inherent deficiency of durability of the vessel walls was next discussed in its relation to presenility and arterio-sclerosis and contrasted with specific instances of inherited vitality and durability of the tissues. Diseases could be classified as inherited (i.e., directly derived from the reproductive cells before conjugation), congenital (acquired during intra-uterine development), and post natal. Thus the subject under discussion was at once limited to effects produced on the germ cells before conjugation and whilst still in the bodies of the respective parents, and the President of the section proceeded to discuss whether the profound biochemical changes in the lymph and blood resulting from the action of poisons elaborated within the body (e.g., those of tuberculosis and syphilis) or introduced from outside (e.g., chronic alcoholism and plumbism) could so modify the male germ cell that the fertilising spermatozoa conveyed specific morbid characters and after conjugation with the healthy ovum led to the transmission of disease to the resulting offspring, and expressed the opinion that the causative agents of tuberculosis and syphilis were unable to pass into the head of the sperm cell without destroying it and so rendering conjugation impossible. Experience showed that syphilis, for example, had but little appreciable effect on the sperm cell and when transmitted to the succeeding generation was almost always associated with maternal infection. Dr. Mott here referred in some detail to his observations on parasyphilitic affections in general and the juvenile form of general paralysis in particular, which led him to agree with Koenig that general paralysis is an acquired disease due to syphilis and that one effect of syphilis upon the germ plasm in highly civilised races was to produce a neuropathic tendency. At the same time he dental irritation some few of the cases of otitis media, especially in young children, not as the direct cause but as a contributory one in depressing the vitality of the affected ear. Such a supposition might account for the difficulty in treating cases of otitis media in children during teething. Arthritis of the temporo-maxillary articulation was another fruitful cause of neuralgia of the ear. Occasionally swelling and œdema of the tissues over the mastoid process were directly due to extension of inflammation from dento-alveolar abscess and might be confused with mastoid disease. Of the effect of removal of the teeth upon the acuteness of hearing he was inclined to be sceptical and although a history indicating such a circumstance was given by some patients it was to be regarded rather as *post hoc* reasoning. Chronic antral suppuration was also a cause of aural neuralgia.

The contribution of Dr. LEONARD G. GUTHRIE (London) to the discussion was read by the honorary secretary in the author's absence. Dr. Guthrie considered that although at one time "teething" and "breeding of the teeth" were so largely held accountable for most infantile diseases, and although the public even now persisted in ascribing all complaints of infancy to teething, perhaps they paid less attention to the subject than its merits deserved. At the very start they were handicapped by not possessing a proper explanation of tooth eruption of a sound physiological nature. In dentition increased salivation might be the only sign, but when pain existed the child often rubbed his ear or the back of his head showing that the pain was referred elsewhere. Convulsions were more common in children below the teething age than during it. Where an unrecognised pneumonic crisis corresponded with the eruption of a tooth it was possible that the one was referred to the other. The reflex theory would not explain all the complaints associated with painful dentition, neither would the pyrexial theory, while the supposition of especial susceptibility at the period of tooth eruption seemed opposed to the fact that dentition was a normal process. Painful dentition was invariably associated with gastro-intestinal disturbance and it appeared that painful dentition depended on a general disturbance with associated sore gums due to gastro-intestinal irritation of unsuitable or sour and fermented food.

Some remarks by Dr. E. CAUTLEY (London) were also read by the honorary secretary. Dr. Cautley considered the relation of the teeth to diseases in early life and in the course of his notes suggested that two main points required consideration—the teeth during eruption and during decay. Teething with "bronchitis," "gum rashes," and so forth were not infrequent expressions, and the diarrhœa frequently existing with teething was often neglected from its supposed origin in the mouth, and Dr. Cautley considered that a diagnosis of teething covered numerous sins of omission in the investigation of infantile ailments. Febrile attacks associated with sore gums might result in decrease of digestive juices and overfeeding to allay the fretfulness wrongly ascribed to hunger. The association of rickets with delayed and defective dentition was important. Pure reflex disturbances from diseased teeth were rare; in a few cases retraction of the head, common in meningitis or pneumonia, might be produced dentally. Fits were very doubtful reflex phenomena and were rarely ended by the eruption of the supposed offending tooth. Much more stress was to be laid upon the importance of decay of the teeth as a cause of ill health in early life than upon the process of eruption.

Dr. ROBERT HUTCHISON (London) considered it very doubtful whether the many disorders commonly and popularly ascribed to reflex nervous effects of dental origin had any relation to the process of dentition. The hypothesis of a "reflex exciting cause" was too often dragged in to explain something for which no adequate cause could be obtained. Convulsions were a particularly good example of this condition now generally recognised as of rachitic origin, while the unstable condition of the whole nervous system associated with this disease allowed the action of many exciting causes of which the cutting of teeth might be one although very far from the commonest cause of convulsions. A much more prominent rôle was to be ascribed to colic. A few remote disorders were aggravated by dentition, such as bronchitis and diarrhœa. A reflex congestion of the bronchial tubes might be associated with swollen and painful gums, thus predisposing to bronchitis, and the aggravation of eczema of the face appeared to be associated with reflex dental origin. The whole subject, however, was one upon which it was impossible to speak dogmatically.

The PRESIDENT of the section congratulated the section on the excellence of the discussion which on his motion was adjourned until the next day.

THURSDAY, JULY 27TH.

Sir VICTOR HORSLEY (London) continued the adjourned discussion. He said he was greatly pleased at the establishment of a section of dental surgery and that it was an excellent thing from both the general as well as the dental surgeons' point of view; moreover, the dental surgeon almost invariably saw the earlier manifestations of pathological changes involving the fifth nerve while the general surgeon usually did not see the cases until the later stages. The earlier changes might be termed congestive and the later cicatricial in neuralgias of the trigeminal nerve to which he would confine his observations. The cause of the neuralgia might be either central or peripheral and after reading the extract of Mr. Mummery's paper and the remarks of Dr. Risien Russell and other contributors to the discussion he thought that it was possible to diagnose between neuralgias of central and peripheral origin; it was difficult to classify but it was becoming increasingly easier. The cases of peripheral origin were those especially seen by the dental surgeon and in some of these peripheral cases, such as chronic osteitis of the alveolus and tooth sockets, an ascending neuritis had been traced. Bilaterality involved a serious question for the patient. The diagnosis between functional and organic disease, although difficult, was possible. Hypersecretion, such as increased lacrymal or salivary secretion, when associated with the irritation of the neuralgic attack, was a diagnostic sign of the organic origin of the neuralgia. Sir Victor Horsley, in continuing, proceeded to give the details of two cases in which the Gasserian ganglion was removed upon both sides. Loss of muscular movement of the jaws would follow removal of both ganglia but in these two cases the motor root on one side was left. Slight obliquity of articulation occurred but was not very noticeable and the neuralgia was cured. Neuralgias of central origin were due to primary neuritis of the ganglion or a neuritis spreading to it, acute inflammation of unknown cause, inflammatory changes due to the "micrococcus of herpes" and sclerotic and cicatricial inflammation. In most cases the ganglion was flattened by cicatricial tissue, sometimes congested and swollen. In these cases resection of the Gasserian ganglion was the only permanent cure. Other treatment was generally of a temporary nature, nerve section usually being followed by union in two years' time. The risk of the operation, although a serious one, was not very great. More than 100 cases had been operated upon, so that it was possible to talk in percentages. The accidental death-rate was 7 per cent., including hæmorrhage and septic infection. Up to 55 years of age the rate was very small and practically only due to sepsis; above 55 hæmorrhage associated with arterio-sclerosis, to which these patients were liable, caused 5 of the 7 per cent. of deaths. Eye risks were still smaller, but though the eye was not so often lost now there was still some unknown factor which caused keratitis.

Mr. F. J. BONNET (London) regretted the absence of Mr. W. Lang who was to have taken part in the discussion and who would have given a valuable contribution from the standpoint of the ophthalmic surgeon. Affections of the eye associated with, or due to, dental lesions had been recorded by Mr. Henry Power and Sir W. J. Collins amongst others, while not a few cases had from time to time been recorded by dental practitioners, and the speaker would confine his remarks to the dental surgeon's point of view. The vagaries of tooth disease were well known to dental surgeons and the dental practitioner was therefore able to form a clear idea of the class of case likely to be responsible for changes in the eye. By far the largest number of cases of eye disease associated with dental lesions were due to direct spread of disease from the jaws rather than to reflex disturbance. Thus, in a case described by Mr. Henry Power as a typical example of reflex amaurosis of dental irritation there was swelling of the face with discharge of pus in the neighbourhood of the lower eyelid. In looking over the reports of cases he found constant record of dead teeth and Sir W. J. Collins especially called attention to the undoubted evidence of the spread of oral inflammations in abused as leading to fallacious conclusions, such fallacies as they give rise to were due not to the methods themselves but to faulty methods of application. The problem set the statistician for solution in the present instance might be stated as "given a certain disease in some or all of a man's parents, grandparents, collaterals, &c., what was in each case the probability of the disease occurring in the man himself?" and provided the requisite data were forthcoming the problem could be solved with mathematical accuracy and precision. The requisite data were, first, the definition of a more or less homogeneous class—that was to say, a class of people belonging to more or less the same race and living under similar conditions as regards climate, housing, nutrition, &c.; secondly, the percentage incidence of the particular disease, as distinct from the mortality, in the class already defined; and thirdly, having defined the class and divided it into those who suffer from the disease and those who do not it was necessary to determine for each of those divisions what number possess ancestors or collaterals suffering from the disease. In other words, if it was desired to estimate the exact amount of force exercised by heredity in the production of a disease it was not sufficient to know the family histories of the people suffering from it; the family histories of people of the same class who did not suffer from it were also needed. Whilst it was impracticable to investigate every member of the defined class great care was needed in the selection of truly representative samples, for if genuine random samples were taken the error would be certain and determinable and would vary inversely with the extent of the sample taken.

Mr. C. C. Hurst, F.L.S. (Burbage, Leicestershire) appealed to the medical profession to help in the good work of obtaining facts on the heredity of disease and suggested that such facts should be carefully obtained by a study of individual histories and pedigrees. He pointed out that Mendel's law of heredity which had only recently become generally known, although very simple, was undoubtedly of the highest importance. This law had been clearly shown to hold good for nearly all simple characters in plants and animals and it seemed possible that the more complicated inborn or inherited characters, such as those of disease, would also follow the same law.

Dr. A. W. Gilchrist (Nice) suggested that the discussion had the utility of demonstrating that the aspect and claims of philosophic medicine were not neglected. He propounded the questions, what was heredity? and what was disease? and beyond the conventional definition that heredity was a virtually passive link in the succession of individual existences confessed his inability to furnish adequate answers.

The President of the section briefly summed up the chief points in the discussion and Dr. Wright (Federated Malay States), in reply to a question from the President of the section, observed that the adults of certain aboriginal races exposed to infection by the quartan malarial parasite developed a marked immunity, whilst their offspring remained readily susceptible to the same infection.

DENTAL SURGERY.

Wednesday, July 26th.

This section met under the presidency of Mr. Morton Smale, when Dr. J. S. Risien Russell (London) introduced a discussion on

Toothache, Neuralgia, and Remote Affections of Dental Origin.

He said that he left to Mr. J. H. Mummery the task of dealing with morbid affections of the teeth and their effects, and devoted his attention chiefly to the class of case in which the teeth were not at fault but other morbid conditions caused pain referred to them or to regions well recognised as the seats of pain of dental origin. He pointed out that many such patients consulted dental surgeons in the first instance, so that it was in their power to direct them into the proper channels where the real nature of their disease could be recognised and treated. The affections of the nose and ear were left for others to deal with, as were the affections of childhood incidental to the discussion. He passed in review general conditions, such as anæmia, malaria, diabetes, and the debilitating effects of diseases like influenza, and made brief reference to certain rare affections such as facial hemiatrophy. He warned his audience to be on their guard against hysteria and in dealing with neurasthenia he emphasised the importance of never ceasing to examine for indications of obscure organic disease. He laid special stress on cases of epileptiform neuralgia (tic douloureux), in which affection the extraction of teeth was worse than useless and in which the extirpation of the Gasserian ganglion offered the only possibility of certain cure, a procedure which he had no hesitation in recommending owing to the highly satisfactory results that were to be obtained by the operation as devised by Krause. Another class of case in which he regarded it as of the utmost importance that the dental surgeon should recognise that something other than the affection of the teeth was responsible for the pain for which he might be consulted was disease of the accessory sinuses, and he emphasised the extreme importance of the early recognition of cases where malignant disease was responsible for the pain. A third group of cases in which the dental surgeon might have opportunities of assisting to a correct diagnosis in early stages of the affections was that in which intracranial disease occasioned pain in the distribution of the fifth nerve, in which affection he would refer especially to the effects of intracranial syphilis and to tumours at the base of the brain which involved the nerve. In conclusion, he invited discussion, especially on the last three groups of cases to which he had directed attention.

Mr. Mummery (London) said that in following Dr. Risien Russell it only remained for him to confine his remarks to the more particularly dental surgery aspects of neuralgias. The full discussion on oral sepsis which took place at the last meeting of the Association at Oxford rendered it unnecessary to deal with that question in the present instance. The subject would be considered under certain headings related: first, to diseased conditions of the tooth pulp; secondly, to affections of the dental periosteum; and thirdly, to difficult eruption and malposition of the teeth. Pain in the course or distribution of a nerve was, like toothache, not a disease *per se*, but a manifestation of irritation at some one or other point of the nerve and its branches. The areas mapped out by Head showed that the several teeth exhibited certain pain localisations, the area affected including the special tooth involved. Neuralgia occurred in edentulous jaws and also in the wasted alveoli of teeth that had been lost. All diseased conditions of the teeth might give rise to neuralgias and, most importantly, morbid affections of the tooth pulps. After referring to the work of Dr. W. H. Gaskell and Dr. D. Ferrier and the important developmental relation of motor and sensory roots as shown by their work, he dealt with the two divisions of neuralgic pain of neuralgia minor—viz., true neuralgia minor and visceral referred pain—the chief differences being that in visceral referred neuralgia the areas of pain were not coincident with the distribution of the branches of the fifth nerve, whereas in true neuralgia minor this was the case. Neuralgia minor closely resembled neuralgia major or neuralgia quinti-major (tic douloureux) at first but it was impossible to find any connexion between the pain and any diseased organ to which the pain was referred. Neuralgia minor caused typical darting pains, but the pain followed the distribution of the peripheral nerves and was not associated with hyperæsthetic areas as was visceral referred neuralgia. There were maximum spots in these tender areas. Mr. Mummery then discussed the various pain areas and tenderness areas associated with the special teeth, to which scarcely sufficient attention was generally paid by the dental surgeon. He then proceeded to detail some cases of neuralgic pain and the evidence obtainable of its origin from a consideration of the pain distribution. He referred to various other examples of reflex disturbance, including vomiting, eye and ear affections, trophic changes, and emphasised the extreme importance of excluding dental causes in all cases of obscure neuralgia, which was rendered still more essential from the fact that apparently quite minor dental affections were associated with very considerable neuralgic pain.

Dr. Urban Pritchard (London) continued the discussion and dealt with various affections of the ear, nose, and throat associated with dental origin. Such cases were, however, by no means so common as was generally supposed, "earache," especially in childhood, being considered by otologists as due to local inflammatory causes rather than to reflex irritation connected with dentition. In adults true neuralgia was more common and true neuralgia of the ear was more frequently due to dental reflex pain than to any other cause. Occasionally he was inclined to attribute to reflex individuals so treated and at the same time the blood condition improved and the local affection began to clear up. In a number of the cases so treated the local discharge of pus from the alveolar sockets ceased and the teeth became firm again. The acneform eruption on the face improved and in one instance a deep acne with much pustule formation associated with Rigg's disease entirely disappeared. Two cases of chronic nasal suppuration had been treated. One, a chronic antral empyema, which had been operated upon four times and at the time of injection was still discharging and was also causing neuralgic pain, entirely cleared up in three months. Details of other cases were given. In estimating the opsonic index he had observed that the most important factor was the time during which the serum was allowed to act. In a series of experiments the number of bacteria taken up by the corpuscles was proportionate to the time in every case, while no alteration was observed in the ratios by using one or three volumes of serum or corpuscles. The lassitude so frequent in the class of oral suppuration described was rapidly lost under the effect of the injections. The method of treatment promised to be very advantageous in treating alveolar pyorrhœa (a notoriously difficult disease to eradicate), by increasing the resistance to the bacteria causing the suppuration. The local treatment was, however, by no means to be neglected. A table illustrating the various alterations of opsonic index in relation to injection was also given. The negative phase of Wright was well marked and in some cases showed a marked prolongation; in two such cases nuclein had been administered and apparently produced a diminution in the length of the negative phase. Some of the cases showed a secondary negative phase after the positive one. Staphylococcal injections were contraindicated in cases of kidney disease owing to the selective action of the bacteria for those organs, as shown by the pyonephrosis and cortical abscesses produced in the rabbits inoculated with the cocci obtained from the pus in the cases described.

TROPICAL MEDICINE.

Wednesday, July 26th.

Professor **Rubert W. Boyce** (Liverpool), the President of the section, delivered an introductory address entitled

The Year's Progress in Tropical Medicine.

He stated that the record of the progress of tropical medical science, if perhaps not rich in discoveries as last year, showed both an increase in the amount of careful scientific observation and the practical good of the application of scientific knowledge to the prevention of disease over an ever-widening area of the world. Among many subjects of interest none perhaps was more worthy of note than the fact that some of the natives of the Gambia in whose blood Dutton originally detected the trypanosoma had since developed and died from sleeping sickness. During the past year Thomas had conducted an exhaustive experimental inquiry on the treatment of sleeping sickness and found that arsenic compounds in the various trypanosoma diseases of the lower animals had afforded encouraging curative results. In connexion with the Leishman body excellent work had been done by Rogers, Leishman, Donovan, Christophers, Balfour, and others. Bentley had contributed to our knowledge of protozoology, James and Patton had described leucocytozoa in certain animals, and Balfour and Christophers had found hæmogregarines in the red cells of certain animals. Ross and Milne had communicated the interesting discovery that spirochætæ were present in the blood of cases of tick fever and Todd and Dutton had succeeded in infecting the monkey and rat by means of ticks infected by feeding upon the blood of cases of tick fever in man. They concluded that tick fever was clinically identical with relapsing fever and that the transmission of the tick was not merely mechanical. Greig and Gray had been working on sleeping sickness in Uganda, and Dutton and Todd had followed sleeping sickness and tick fever along the waterways of the Congo. Thomas and Breine were engaged in the investigation of yellow fever on the Amazon, and Bruce had succeeded in elucidating the manner of infection in Malta fever. Surely no other department of medical science could show such activity as this nor did there exist one that deserved more strongly to be supported.

Dr. **John L. Todd** contributed a paper by himself and the late Dr. **J. Everett Dutton** entitled

The Nature of Human Tick Fever in the Eastern Part of the Congo Free State, with Notes on the Distribution and Bionomics of the Tick.

On Nov. 26th, 1904, Dr. Dutton and Dr. Todd published the statement that a spirillum was the pathogenic agent of the human tick fever that occurred in the oriental province of the Congo Free State and that they had succeeded in infecting monkeys with the spirilla through the bites of ticks. Tick fever, according to the observations of Dr. Dutton and Dr. Todd, was a relapsing fever produced by a spirillum probably identical with spirochætæ Obermeieri and this organism was transmitted by the bite of a tick subsequently proved to be the ornithodorus moubata. The history of human tick fever in the oriental province of the Congo Free State dated back to the time of Livingstone. Hinde, in 1892–94, stated that the natives of the Congo attributed some of their illnesses to the bites of the ornithodorus. The symptoms were liable to be mistaken for other diseases and by the microscope alone was it possible to clear up the diagnosis. The incubation period of tick fever was about one week. The chief symptoms were headache, browache, backache, distaste for food, vomiting, slight diarrhœa, with decided increase of temperature. The attack usually lasted three or four days, ending in free perspiration. There were usually three or four attacks with an intervening period between each of from five to ten days. Splenic enlargement, herpes, epistaxis, and hiccough were frequent accompaniments. Experiments indicated that the ordinary laboratory animals were not killed by the disease. In the blood the spirillum could easily be found when plentiful as a rapidly moving spiral thread; when scanty it was necessary to stain dehæmoglobinised blood stained by a modification of Romanowsky's method or a weak solution of carbol-fuchsin. The distribution of the human tick in the Congo Free State and its bionomics were also entered into in detail in the paper and the writers concluded that: (1) tick fever was clinically identical with relapsing fever and had for pathogenic agent a spirillum; (2) the spirillum was probably spirochætæ Obermeieri; (3) the tick ornithodorus moubata could transmit the spirillum from animal to animal; (4) the transmission was probably not merely mechanical but some developmental process was carried on in the tick; and (5) a considerable degree of immunity or tolerance to the spirillum could probably be acquired.

Mr. **R. Newstead**, of the Liverpool School of Tropical Medicine read a paper

On the Pathogenic Ticks concerned in the Distribution of Disease in Man, with Special Reference to the Differential Characters in Ornithodorus Moubata.

He said that ticks (ixodoidea) belonged to the class arachnoidea (spiders, mites, &c.), order acarina. This super family (ixodoidea) consisted of two sub-families—the argasinæ and the ixodinæ. The former was composed of two genera, argas and ornithodorus; the latter comprised nine genera. Mr. Newstead had found that in many respects the habits of the ornithodorus moubata were not unlike those of argas persicus, but the inert character of the larva of ornithodorus moubata was unique among the ixodinæ, in that it passes the whole of its life within the egg. The female ornithodorus moubata laid eggs which were hatched not as larvæ but as nymphæ, although on the ninth day the larva was fully formed and the egg shell split but the young tick remained until the fifteenth day when as a nymph it escaped simultaneously from its larva covering and egg shell.

Dr. **L. W. Sambon** (London) said that if the spirillar disease was carried by the ornithodorus moubata in Africa then probably the disease miana in Persia carried by argas persicus was also a spirillar disease—possibly identical with relapsing fever. The question was whether the relapsing fever in India was also carried by a tick. Recent facts prove the correctness of the statement that bugs were the carriers of relapsing fevers in southern Russia and other parts of Europe. Dr. Sambon referred also to the extraordinary changes which take place in the stomach of the tick after feeding on blood: the cells take up part of the blood and empty it directly into the body cavity.

The **President** of the section referred to Christie's observations in Uganda that the tick carried the filaria perstans.

several of so-called reflex amaurosis of dental origin. In one case recently blepharospasm was associated with septic infiltration and chronic periostitis of a lower wisdom tooth. Pressure on the tooth stopped the spasm. Several other cases of orbicular spasm were recorded. Finally, Sir W. J. Collins, in searching the records of the Ophthalmological Society, found no record of glaucoma, reflex amaurosis, phlyctenular ophthalmia, opthalmoplegia, or failure of accommodation attributed with any assurance or proof to dental lesions.

Mr. P. SIDNEY SPOKES (London) thought that the three papers of Dr. Guthrie, Dr. Cautley, and Dr. Hutchison were a valuable contribution to the question of dental origin of some diseases occurring in children, but the last paper appealed to him the most, inasmuch as Dr. Hutchison admitted that painful dentition might be one cause of infantile disturbance and that at any rate some such condition as eczema might be exaggerated during the period of teething. That reflex irritation of dental origin might be caused by dentition was proved by the occurrence of cough regularly present in some cases during the eruption of successive teeth. Mr. Spokes had seen cases in which there was no stomatitis and no oral inflammation with the exception of a small area over the erupting tooth, and in several of these cases incision of the gum was followed by a cessation of the associated convulsions. There was no suspicion of rachitis or intestinal disease. Mr. Spokes mentioned a case of frontal neuralgia in which the teeth were entirely eliminated as a cause and in which the antrum was opened and found to be normal; the neuralgia entirely disappeared on the discovery and removal of a stone from the bladder by Mr. Rickman J. Godlee.

Mr. H. BALDWIN (London) thought that the previous speakers were inclined to overlook the fact that living irritated rather than dead septic pulps were the cause of dental neuralgia. He mentioned two cases, one in which acute occipital neuralgia at the point of insertion of the trapezius was cured by the treatment of a second upper molar, and the other where mammary neuralgia was associated with a small cavity in a lower second molar.

Dr. E. A. BOGUE (New York) said that he could not adequately discuss the papers contributed to the discussion as that particular line of work had largely passed out of the practice of himself and his *confrères* in New York. One case, however, which came under his own observation was perhaps instructive. A second right lower molar was treated for an exposed pulp and, as the after-history showed, only a portion of the tissue was removed. Pain occurred and was attributed by the patient to the first lower molar. The pulp of this tooth was destroyed. The pain, however, recurred in the antrum, which was opened from the nose, but no diminution of the pain took place. A bicuspid tooth was therefore removed and the antrum explored through the socket with no effect. Subsequently section of the inferior maxillary nerve was performed, together with an incision for the ligature of the external carotid if necessary. Finally, one of the kidneys was removed. At the end of five months the original tooth was removed and the pain ceased.

Mr. FRANK E. HUXLEY (Birmingham) said that the sensitive and painful areas indicated by Dr. Head were valuable as aids to diagnosis but it must be remembered that notable exceptions occurred. He instanced cases of supra-orbital pain associated with a third lower molar; pain in the upper bicuspid region associated with a nasal polypus, the teeth being tender to percussion. Cocaine spray in the nose caused temporary relief of the pain. A third case quoted by Mr. Huxley had all the characters of epileptiform neuralgia associated with increased salivation and lacrymation. There was no dental cause discoverable. A change of residence to another part of the country was followed by diminution in the severity and, finally, entire cessation of the attack.

Mr. J. LEWIN PAYNE (London) described a case of Pure Reflex Pain in a lower second molar which was entirely relieved by treatment of the upper third molar on the same side. He had also seen a case where antral suppuration was associated with hyperæsthesia of the scalp. In determining the cause of so many cases of reflex pain being associated with dental lesions the probable explanation was to be found in the delicate nature of the tooth pulps, their confined position, and their irregular reparative efforts when undergoing chronic inflammation.

Mr. H. A. T. FAIRBANK (London) said that very few of the cases described in the discussion came under observation at he surgical out-patients' department of a children's hospital. Dentition had practically no direct effect upon the ears and he was unable to call to mind a single case in which dental irritation was the cause of pain about the ears. Convulsions were probably intestinal toxæmic manifestations and although stomatitis was common among out patients at children's hospitals yet convulsions, except of a very severe type and associated with much septic absorption, did not occur. Infantile scurvy was also a cause of soreness of the gums. Two cases of pain in the mastoid region in two girls of about seven years of age had been seen by the speaker which were essentially of dental origin and due to carious temporary teeth.

Mr. A. S. UNDERWOOD (London) cited two cases of peripheral neuralgia of dental origin and a case of alopecia associated with marked oral sepsis. He would like to ask Mr. Mummery if there was any chance of direct influence of the dental cause upon the alopecia.

Mr. J. F. RYMER (Brighton) thought the electric currents set up in the mouth by various metals should not be lost sight of in elementary causes of neuralgia.

Mr. K. W. GOADBY (London) called attention to the presence of minute and even microscopic defects or cavities in the enamel of teeth, which were found to be connected firstly with infection of the dentine and secondly with direct pulp infection by capillarity along the dentinal tubes. He cited a case in which rheumatoid arthritis of the temporo-maxillary joint produced reflex pain in the ear and first upper molar tooth.

Mr. J. G. TURNER (London) said the utility of Head's areas could hardly be sufficiently insisted upon and the suggestions of Sir Victor Horsley that organic diseases could be differentiated from functional was of the utmost importance in the diagnosis of trigeminal neuralgia from cases of dental origin, while the ascending neuritis by exostosis and sclerosis of the bone involving the terminal filaments of the fifth nerve was worthy of much attention. Mr. Turner then considered the neurasthenic type of neuralgia which was at times associated with the dental neuralgia and detailed a case where the cause was directly referable to the involvement of the nerve endings in the spicules of bone left after difficult extraction. In some neurasthenic cases suggestion appeared to be of some value and he had removed a tooth from a neurasthenic patient, without an anæsthetic and with no pain, by suggestion. Mr. Turner cited other causes of reflex neuralgia and further discussed the relationship of Head's areas to the individual teeth.

Dr. J. O. BROOKHOUSE (Nottingham) detailed a case of neuralgia of the fifth nerve in which the pain was limited to the angle of the mouth. There was no hypersecretion. Operation upon, and section of, the infraorbital branch was performed but the pain recurred. The inferior dental nerve was stretched but in 18 months the pain recurred. In the speaker's own practice for over 40 years great attention had been always given to the hygiene of the mouth and not a few cases of pain of dental origin referred to other organs had been seen. Rheumatism, or something almost indistinguishable from rheumatism, was frequently associated with oral sepsis.

Mr. W. ARMSTON VICE (Leicester), who described a case of neuralgia of obscure dental origin, and Mr. J. S. SLOAN (Leicester) also joined in the discussion.

The PRESIDENT of the Section thanked the various contributors for their assistance in an extremely important and interesting discussion and invited Mr Mummery as one of the openers to reply.

Mr. MUMMERY briefly replied.

Mr. GOADBY read a paper on

The Method of Vaccine Treatment in Chronic Alveolar Osteitis.

The affections known as Rigg's disease, he said, were of several varieties. Among these one class of case, although not showing signs of acute infection or toxæmia, had many general symptoms referable to the mouth lesions. The blood examination in such cases showed a distinct though slight anæmia, which anæmia did not clear up under the usual general treatment adopted. There was often an acneform eruption on the cheeks and also of the nose. In the alveolar sockets and pus of the cases he had found staphylococci which, however, showed some differences from the ordinary staphylococcus aureus. He had tested the opsonic reaction of the patients and found it below normal for the staphylococcus obtained from the mouth. Vaccines were therefore prepared and the cases were inoculated. A marked improvement in the opsonic index was observed in when it is desired to rouse the fire into activity. The Bostel patent hydraulic drain jointer and cleaner was also exhibited. This is an ingenious apparatus designed for the repairing of sewers or drains without "grubbing up" the pipes or the soil in which they are laid. A cylinder of freshly made cement passes along the pipe under pressure and cement escapes into any opening or defect which it effectually seals. Messrs. Young (72, Mark-lane, London, E.C.), showed their patent hygienic bins made of galvanised steel without internal corners or crevices, so that no lodgment or retention of the contents can take place when the bin is in use or emptied. Messrs. J. Defries and Sons, Limited (146 and 147, Houndsditch, London, E.C.), showed a model of the Equifex steam disinfector besides various types of Pasteur filters and disinfectant compounds, including cyllin, formaldehyde, and paraform tablets. The Jeyes' Sanitary Compounds Company, Limited (64, Cannon-street, London, E.C.), also exhibited a number of preparations of "cyllin," a disinfectant fluid which is said combines the maximum of efficiency as a bactericide with the minimum of causticity and toxicity to the higher forms of life. Messrs. Newton, Chambers and Co., Limited (Thorncliffe, near Sheffield), exhibited izal and its preparations. Izal itself is a powerful germicide though non corrosive and non-poisonous. Compared with previous years it will thus be seen from this notice that the exhibits of the sanitary section were by no means very diverse in character.

ASYLUM REPORTS.

Inverness District Asylum (*Report for the Year ending May, 1904*).—The report of the medical superintendent of this asylum, Dr. R. B. Campbell, states that 178 patients were admitted during the year, which is a large number for an asylum of this size. The average for the past ten years is 160. Of the 178 patients admitted 140 were first admissions. The discharges amounted to 108, of whom 78 had recovered. The deaths numbered 41, giving a death-rate of 6·4 per cent. on the average number resident, as compared with 9·7 per cent. in the Royal and district asylums of Scotland for 1903. Pulmonary tuberculosis accounted for 29·2 per cent. of the deaths—a high proportion. The average number resident during the year was 637. The recovery-rate, calculated on the admissions, was 43 8 per cent.—a high rate decidedly and comparing well with the 39 per cent. of the Royal and district asylums of Scotland. The number of readmissions has been large during the past few years, which is ascribed to the discharge of quiet and manageable patients; in many cases these break down outside asylum care. Nevertheless, it is stated that the system of boarding out harmless cases in private dwellings proves successful in the majority of cases. During the past four years no fewer than 160 patients have been discharged unrecovered and sent to their friends or boarded out with great relief to the institution. Homes are easily found, it is stated, for industrious patients but not for idle ones. No less than 13 of the admissions were over 70 years of age. 80 of the 178 were regarded as curable. Heredity of insanity was traced in 52 of the admissions; alcoholic excess in 19. During the spring there was "an epidemic of rheumatism, evidently of an influenzal nature"; the type was mild; both inmates and staff were attacked. One fatal accident occurred, a patient breaking away from his attendant whilst on his way to the bath and thrusting his head into the hot water running from the tap of the latter, which resulted in severe scalding and death from shock. The District Board of Lunacy, recognising the value of agricultural labour as a curative agent in the treatment of certain phases of mental disorder, has purchased a further 200 acres of land. The benefits anticipated from such labour and from a plentiful supply of home milk (the allowance of breakfast milk has been doubled) as distinct from contract milk are likely to be realised. From the two reports of the Commissioners in Lunacy the asylum is evidently fulfilling its purpose with efficiency. From the list of the asylum officials it appears that there is only one assistant medical officer, which is a small allowance for an institution of this size.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 4, 1827.

SMALL POX.

To the Editor of THE LANCET.

SIR,—My attention has been excited to a leading article[1] in your Journal, No. 202, for the last month, headed, "Iniquity of inoculating for the small pox," and although I am perfectly prepared to subscribe, in the full extent, to the correctness and propriety of the observations you have made in exposing and denouncing a practice that cannot be defended upon the principles of justice, of morals, or of humanity, yet I cannot forbear expressing my surprise that you, who upon almost every other occasion appear to be possessed of the eyes of Argus, should have found it necessary to travel into one of our Western Counties to show up the character of one who openly manifests his disregard and contempt of public opinion, in opposition to nine-tenths of the more enlightened and disinterested members of his profession. I say, Sir, I am rather surprised that you should have so done, because I regret to say there are some practitioners, in the environs of this great metropolis, who are daily doing, *under coverture*, what this person has the greater manliness and honesty to do *openly*, and probably under the persuasion that he is acting right; whilst the individuals to whom I now allude profess to be the *disinterested friends of vaccination*, and yet are formed of such accommodating materials that they will consent to scatter the poison of small pox, by *inoculation*, at the invitation of the most illiterate and prejudiced members of the community. This, Sir, is no overcharged statement, the truth of which can be substantiated by irrefragable testimony. Nearly twenty years ago, I made a proposition to two of the most influential practitioners in my own neighbourhood, to enter into a covenant with each other to decline small pox inoculation altogether, but I am sorry to say with no success; and notwithstanding I expostulated, and argued upon the imperative propriety of the measure, in reference to the interests of science, of the public health, and morals, all my efforts were vain. The practice was then, and still is, defended upon one ground, *self interest*, and I was silenced with the *dignified* and *disinterested* reply, Mr. ——, though he approves of cow pox, inoculates for the small pox, and if I do not I shall *lose* my patient! This temporising and disgraceful policy continues still to be pursued by the parties to whom I have alluded, and, to my shame I confess, I have, in some instances, been compelled to follow the influence of bad example, rather than suffer my prejudiced and obstinate applicant to pass over to my competitors.

It is to be lamented that there has been, perhaps in every man's practice, a few cases of *variolous disease* subsequent to vaccination; those which have fallen under my own observation have been of the modified kind, distinct and mild in their character, and accompanied with slight constitutional disorder. It is to be deprecated that so much popular hostility should still exist against the adoption of this great national antidote to one of the most loathsome and destructive contagious diseases that ever desolated the world. But the longer I reflect upon the subject the more I am convinced that nothing short of a legislative enactment will ever render its introduction universal in our native island. Hoping that your able and unwearied exertions will hasten the consummation of so desirable an object,

I remain Sir,
Yours, very respectfully,
VERITAS.

London, July 26, 1827.

---

[1] See "Looking Back" in THE LANCET, July 15th, 1905, p. 176.

WEST CORNWALL INFIRMARY.—The Local Government Board has sanctioned the contribution of £100 by the Penzance board of guardians towards the new West Cornwall Infirmary at Penzance.

Major R. Ross (Liverpool) mentioned the presence of a small tick which attacked Europeans in India.

Dr. J. C. GRAHAM (London) stated that he had seen a small green tick which attacked man in Sumatra.

Dr. A. J. CHALMERS (Colombo) referred also to a virulent tick in Ceylon.

Mr. JAMES CANTLIE (London) described the case of an officer engaged in the Thibet campaign who was suffering from a form of sore ascribed to the bite of a tick.

Fleet-Surgeon P. W. BASSETT-SMITH, R.N., contributed a paper on

Bruhl's Disease, with Special Reference to the Blood Changes found, and Connexion with the Leishman-Donovan Bodies.

Acting upon a suggestion made by Dr. J. C. Low, of the London School of Tropical Medicine, he examined the blood of two patients at Haslar suffering from splenic anæmia or Bruhl's disease as to the presence of the Leishman-Donovan body. In neither case did he find the parasite and concluded that this class of cases came under the category of primitive splenomegaly in contra-distinction to the true tropical splenomegaly in which the Leishman-Donovan bodies played so important a rôle

Sir PATRICK MANSON (London) communicated

Notes on Two Cases of Febrile Tropical Splenomegaly (kala-azar) and a Suggestion.

The cases were typical cases of kala-azar in which Leishman-Donovan bodies were demonstrated. The life-history of the Leishman-Donovan body had not yet been satisfactorily worked out. The question of the identity of the Leishman-Donovan body and that found in oriental sore was an interesting one. In tropical splenomegaly the Leishman-Donovan body was found in the spleen, liver, bone marrow, glands, intestinal ulcers, and elsewhere but in oriental sore it occurred only in the sore; the former was accompanied by marked constitutional disturbance but the latter by apparently local changes only. Oriental sore was a disease of countries in which the camel was a prominent domestic animal and some held that the disease was conveyed by the camel. In this way oriental sore might bear the same relation to kala-azar that vaccinia did to small-pox; the virulence of the kala-azar germ (seeing that the germs in kala-azar and oriental sore were identical) might be got rid of whilst passing through the camel as the small-pox germ was deprived of its virulence by passage through the cow. Did these suggestions prove to be correct a means of preventing kala-azar would seem ready to hand.

Major Ross stated that mule drivers as well as camel drivers were liable to oriental sore.

Dr. W. M. GRAHAM (Sierra Leone) contributed a paper on

The Guinea-worm and its Hosts.

Dr. Graham's observations were made on the Gold Coast where he was struck by the importance of Guinea-worm disease and the number of native troops yearly incapacitated by it. He found that the infection of man by the worm took place during a few months of the year and that it did not occur during the other months. In Salaga the month of greatest incidence was May, but in Gambia it was June; this would appear to show periodicity. The fact that the cyclops (the presumed intermediate host) showed its maximum manifestation during the period corresponding to the maximum infection in man also contributed towards the belief in periodicity.

In the discussion upon Dr. Graham's paper on Guinea-worm the following took part: Dr. W. C. BROWN (Penang), Dr. CHALMERS, Dr. F. M. SANDWITH (London), Dr. SAMBON, Dr. W. T. PROUT (Gold Coast), Mr. J. T. CLARKE (Perak), Dr. C. F. HARFORD (London), Mr. NEWSTEAD, and Dr. CLAUS SCHILLING (Berlin).

THE ANNUAL EXHIBITION.

III.—FOODS AND FOOD PRODUCTS.

THE exhibits coming under this division were not a strong feature of the exhibition this year and they included many well-known preparations which have been shown on previous occasions. Mention may be made of the specialities of Bovril, Limited (152–166, Old-street, City-road, London, E.C.), including virol which has now had the trial of experience with excellent results, rations, and essence of beef; the milk preparations of the Aylesbury Dairy Company, Limited (St. Petersburg-place, Bayswater, London, W.), comprising humanised milk, a concentrated preparation which on dilution gives a fluid of the composite of human milk, pollyta, a solid milk food, and humanised sterilised milk; Horlick's malted milk (Horlick's Malted Food Company, 34, Farringdon-road, London, E.C.); shredded wheat (The Shredded Wheat Company, 6 and 8, Eastcheap, London, E.C.), containing the entire constituents of the wheat berry steamed, cleaned, and shredded; a series of digestive ferments and meat foods by Armour and Co., Limited, of 46A, Holborn Viaduct, London, E.C., including pepsin, pancreatin, bone marrow, and the active principle of adrenal substance; Mellin's dietetic preparations (Mellin's Food Works, Peckham, S.E.), comprising food biscuits, infants' food, and "lacto," prepared from the infants' food and fresh cow's milk (the exhibit included a specially designed feeding bottle); milk foods by Henri Nestlé (48, Cannon-street, London, E.C.), including full-cream condensed milk, milo food, and chocolate; starchless foods by Messrs. Callard and Co. (74, Regent-street, London, W.), including bread, biscuits, cakes, as well as sugarless marmalade, jam, jellies, and beverages; albene, a pure, refined vegetable fat, a substitute for cooking purposes for butter, by Messrs. Broomfield and Co. (83, Upper Thames-street, London, E.C.); a fluid malt extract by M. Hoff (29, New Bridge-street, London, E.C.) (the exhibit included also ironol, an organic iron compound said to be easily assimilated); gluten bread, biscuits, and flour by Messrs. G. Van Abbott and Sons (Baden-place, Crosby-row, Borough, London, S.E.), and almond bread, &c.; an excellent series of digestive and other products by Messrs. Fairchild Brothers and Foster (Snow-hill Buildings, London, E.C.), including peptogenic milk powder, panopepton, lecithin, pepsin, and zymine or pancreatic extract, and zymine peptonising tubes for peptonising milk; patent barley and groats by Messrs. Kent, Robinson and Co., Limited (Denmark-street, St. George's-in-the-East, London, E.); diabetic foods of the Manhu Food Company (23, Mount Pleasant, London, W.C.), of which it is stated that the carbohydrates are changed and made so easily digestible as not to aggravate the symptoms of the disease; specialities for invalids, comprising essences of beef, mutton, veal and chicken, and jellies by Messrs. Brand and Co., Limited (11, Little Stanhope-street, Mayfair, London, W.); diabetic foods, bread, and biscuits, and invalids' and infants' foods by the Cheltine Foods and Chocolate Co., Limited (Cheltine Works, Cheltenham); and maltine plain and with pepsine and pancreatine, with hypophosphites, iron, or cod-liver oil, by the Maltine Manufacturing Company, Limited (24 and 25, Hart-street, Bloomsbury, London, W.C.) (the exhibit included the liquid peptonoids and beef peptonoids of Messrs. Carnrick and Co. of the same address as the Maltine Company.

Less well-known than the foregoing owing to their comparatively recent introduction was the pioneer milk sugar of the Pioneer Milk Sugar Company (24, Minories, London, E.C.). As our analysis has shown this preparation is practically pure milk sugar and therefore is suitable for use in the preparation of humanised milk; "Veda" bread and oat foods of the "Veda" Food Company (34, North Bridge, Edinburgh), which are produced by a new method of treating wheat and oats so that the carbohydrates are largely reduced to a soluble condition—the bread is excellent and, judging from it analysis, should be considerably more nutritious than ordinary bread; Moseleys food, prepared from wheat an dextrinised and containing therefore a large percentage o soluble carbohydrates besides proteid (Foods, Limited Stockport); and wheat-meal brown bread by Messrs. J Reynolds and Co., Limited (the Albert Flour Mills Gloucester), said to be made from selected wheat, and i certainly has an excellent flavour, which is one indication a any rate that such is the case.

IV.—SANITARY APPLIANCES.

This section was not very representative, the exhibits consisting chiefly of disinfectant preparations and disinfecting appliances. An exception appeared in the case of the exhibit of Messrs. D. T. Bostel and Sons (71 and 73, Ebury-street, London, S.W.). This firm showed the Bostel patent natural seat and water-closet which was recently noticed in THE LANCET. The closet and seat aim at securing the natural squatting position during defæcation and the model exhibited met with the approval of many of the visitors. Besides was shown the "Bostel fire," which is correctly described as an appliance for heating the room and not the chimney. The grate lifts up so that a draught of air is compelled to go through the bottom and the bars of the grate chloroform having been taken through the mouth. The exact means employed by DEVEREUX to administer the poison was not proved. Probably it was introduced into the milk consumed at tea-time if we can accept his statement that he went out after tea and returned to find his wife and children dead at about 8.30 P.M. As regards DEVEREUX'S criminal responsibility there can be no shadow of doubt. He is a cold, cruel, calculating murderer. His intellectual capacity is of no mean order. He did not even instance the "method of madness." The main features of his mental character are cunning, designing and remorseless villainy. The most that may be said in his favour is that he is a moral degenerate.

The Educative Factor in Hospital Life.

A PERFUNCTORY knowledge of the recruiting grounds from which the majority of hospital patients are drawn is sufficient to place the hospital in the front ranks of philanthropic endeavour and it is long since this view has been recognised. The great company of hand-to-mouth workers, the still larger army of regular hands with big families dependent upon their efforts, and above them the stratum of small tradesmen who can afford no higher fee than that which will tide them over the minor ills of life are all to be numbered among the natural inmates of every hospital. The physical benefits conferred upon these classes by the presence of these institutions are so obvious that such agencies as sermons, pamphlets, and bazaars have now become rather reminders than instructors of the public conscience. The hospital is the outpost of our national defence against degeneracy and the boon which is conferred by hospital ministrations upon every modern community is practically immeasurable if hospitals be rightly used.

While the supreme mission of every hospital is the alleviation of physical disability it is well to recognise certain secondary benefits. These may be difficult to appraise with any degree of accuracy but they are nevertheless perfectly real both in their existence and their influence, and the extent of that influence can be judged from many instances which come under direct observation. There is excellent evidence to justify the conclusion that as a social and humanising influence the hospital must rank very high and this aspect of its mission should be more considered than it is to-day. It is perhaps given to the lay observer, less engrossed in the physical if not more responsive to the moral and social welfare of the masses, to realise how beneficently the hospital may fulfil ends that are only indirectly comprised in the healing of the sick. To the layman every whit as much as to the physician or the surgeon the hospital should reveal itself as a school of morals no less than as a temple of healing, a dispensary of manners no less than of remedies, and infinitely more effective in these respects than any number of university extension lectures. For a sojourn in the ward of a hospital is in a very large proportion of cases the first real contact, in any true sense of the word, that many of its patients have had with a culture and refinement which they have hitherto regarded with indifference or even resentment. For a few days or weeks they are lifted, whether they will or not, into an atmosphere to which they have heretofore been aliens and regard themselves, their fellow sufferers, and the day's routine from a point of view that is wholly foreign to their experience. Too ill very often to be at first more than passively conscious of the change, with convalescence and returning strength their minds become tuned to this novel and more cultured environment. Their meals are served according to the principles of simple refinement: not according to the impossible dictates of luxury but after a fashion that might perfectly well be copied in their own little *ménages* at home. They see about them not an ostentatious pride in tidiness and cleanliness but a tacit admission of the necessity of these qualities and the sense of inferiority that accompanies their absence. Here the prized domestic virtues are no fruits of a weekly or yearly effort, but their exhibition forms the undisputed condition of every day and shows the patient that the primary elements of decency and comfort are within the reach of all. When once all this is perceived by the patient there comes a sense of the responsibility of each member of this little society towards the whole, a sense of personal obligation to conform to the general standard. And while this may at first be an effort, yet the satisfactory result is too obvious to escape even the bluntest perception. As a consequence of this it is not hard to see how in a very little while the whole hospital *régime*, which at first may have seemed so strange, will gradually resolve itself before the patient's eyes into a series of perfectly practicable details that with a very little trouble might be practised elsewhere. Again, the prevailing spirit of courtesy and self-restraint, of *bonhomie* under admittedly disagreeable conditions, and above all of an altruism that is not merely sentimental but perfectly healthy and largely unconscious, cannot fail to have a profound moral effect. That a few weeks of hospital life can overcome the crusted habits of years is, of course, too much to expect and experience proves the contrary. But that it may go further to undermine prejudice than many years of extraneous social endeavour is beyond doubt.

In the case of children especially the educative aspect of hospital life is very evident and many curious instances of a double code of morals, manners, and conversation existing side by side in the same child's mind may be observed in any large hospital. The more desirable one may not prevail—this, alas, is too often the case—but its presence, however fleeting, will not have been entirely wasted. The conditions of hospital life are largely artificial but at the same time it is not too optimistic to believe that some of them are applicable to many of the homes to which the patients return. And while the contrast must necessarily be extreme between the well-ordered routine of a large institution, with its rules and regulations and enlightened organisation, and the haphazard everyday domestic life of the patients, yet it is impossible to suppose that some relic of its message does not remain influential. Admitting this, it is only necessary to ponder for a little upon the vast society that a large hospital touches in order to realise the magnitude of its educative influence. Where in-patients are numbered by

THE LANCET.

LONDON: SATURDAY, AUGUST 5, 1905.

Rex v. Devereux.

Nearly six months after committing one of the most revolting murders in the annals of crime, Arthur Devereux was convicted and sentenced to death at the Central Criminal Court on July 29th. In this case Nemesis was slow but sure and relentless. On Jan. 31st the victims of the tragedy—mother and twin children—met their fate. On April 13th their bodies were discovered in a tin trunk stored away in a warehouse at Kensal Rise. Shortly after the latter date Devereux was arrested at Coventry and charged with the capital offence, but it was not until more than three months had elapsed that he took his stand in the dock at the Old Bailey to answer the indictment against him. On two occasions the trial was postponed at the instance of counsel for the prisoner on the ground that important evidence was being sought in his interest. How valueless was that testimony is now matter of history, for all the witness could allege was that some six years ago Mrs. Devereux stated that rather than lead a life of immorality she would kill herself. Considering some of the circumstances of the interview this could not possibly be distorted into a threat of suicide by a dutiful child and chaste wife as Mrs. Devereux was. The other threads, equally flimsy, upon which it was sought to hang the theory of self-murder were: firstly, that 30 years ago Mrs. Devereux's mother suffered "mental disturbance"—probably the delirium of fever—after a premature confinement; and secondly, that her brother mysteriously disappeared two years since. His clothes were found on the shore at Plymouth Hoe but his body was never discovered. That he passed into oblivion is certain; that he destroyed his life is conjectural. No doubt Mrs. Devereux's married life was full of trouble and miseries but she was sustained by the love of a devoted mother and by the ties of motherhood

It was not suggested by the defence that if a murder had been committed another hand than the accused's had executed it. In reply to the usual plea—absence of motive—Mr. Matthews for the Crown said "there never was an adequate motive in any case of murder, and from the point of view of right-minded people there never could be one." We will recite a few of the facts that pointed so strongly to Devereux's guilt: 1. On Dec. 31st, 1904, he took a flat at Milton-avenue and requested the agent not to let the lower flat. The result of this was that he and his family had sole possession of the house. 2. On Jan. 28th he was making preparations for his boy Stanley to go to a school. This was the last date upon which Mrs. Gregory saw her daughter whom she had been accustomed to visit daily. Devereux, whose animosity against his wife's mother was avowedly marked, knew that she was going to the country for some weeks. 3. To more than one individual he had spoken of the twin children as a burden to him. 4. On Jan. 13th, 1905, he sent a telegram in reply to an advertisement for an assistant druggist in these terms: "Would widower, aged 34, do? qualified; one child, six.—Devereux, 209, Shirland-road, N.W." On that date he was married and had three children. To counsel's question "And by March 22nd you were a widower with one surviving child, aged six?" he answered Yes. 5. After the death of his wife and twin children he sold their clothes, left London to live in the country, and placed his boy, aged six years, in a boarding school. In what way did Devereux meet this damning testimony? He said the reason why he did not call in someone when he found his wife and children dead was: "I was frightened because I remembered the argument I had with my wife and because of the ill-feeling which my mother-in-law always bore me." Some circumstances associated with the "Trunk Tragedy" stand out in bold relief and signalise the event as one of the most remarkable of its kind ever chronicled. The fiendish callousness and measured way in which Devereux by his own confession and testimony proceeded with his ghoulish task to place the bodies of his wife and children in the trunk and to secure them from detection by prolonged labours aided by the scientific knowledge which he possessed surpass all ordinary human understanding. The memory of the Crossman case, he said, suggested the means of disposal of the remains but he determined not to bungle his work as Crossman did Having failed to effect his purpose by using zinc sheeting and soldering he covered the bodies with cloths and coated the latter with glue mixed with boric acid. Over all he placed a cover made of pieces of wood firmly fixed by screws and this again he coated with glue. In order to prevent any possible escape of effluvia he filled the keyhole of the lock with sealing wax. This hideous occupation extended over five or six days.

Counsel for the defence avowed that they were not prepared to argue that Devereux was insane at the time of the tragedy nor that he was unfit to plead at the trial but they endeavoured to prove that from hereditary taint he might be expected to act in the extraordinary manner he did when, as he alleged, he found his wife and children dead. Except in a case of such extreme gravity the evidence tendered to the above end would not have been allowed by the Court, for technically it was inadmissible as germane to the issue. Although Mr. Justice Ridley indulgently yielded to counsel's appeal he nullified the effect in his summing up by asking the jury to dismiss the evidence as worthless since it was inapplicable. Briefly we may note that owing to the methods used by Devereux it was possible to identify the features of the deceased ten weeks after death. Sir Thomas Stevenson succeeded in detecting, isolating, and weighing the morphine found in Mrs. Devereux's body, recalling the Hickman case. It was calculated that at the time of death there were four grains in her system and that the liver contained *nearly four times* as much as the stomach, showing the extent to which absorption had occurred. There was no indication of used to carry away the dejecta of the consumer. And matters are not likely to grow better, for the population is increasing, which means that while more water will be wanted the output of sewage will be greatly increased. The introduction of bacteriological processes for the disposal and complete destruction of sewage, it is true, promised results compatible with hygienic requirements; but, remarkably efficient in breaking down putrescible matters as the bacterial agencies appear to be, we have it on the greatest authority that there is no decisive evidence that these agencies will destroy pathogenic entities. It is admitted that London water drinkers are at the mercy of the filter-beds. If these should fail the chances of the outbreak of disease are great and a water-borne disease in London would be too terrible to contemplate, threatening the lives not of thousands but of millions. The evidence, however, that the water-supply of London has been accountable for disease is not convincing and we are not aware that any difference has been shown to exist as regards the prevalence of disease between those who drink water derived from the Thames and those who drink, say, the deep well waters of the Kent division supply. It may be that some day it will be possible to draw a sharp line of demarcation between the two sets of water drinkers by the fact of water-borne disease breaking out in one or the other, but it is devoutly to be hoped not. At all events there can be little doubt that the abandonment of a supply derived from a river which is admittedly used for the carriage of sewage in favour of the adoption of a supply from the pure and abundant watershed of Wales would inspire a feeling of considerable confidence amongst London water drinkers and would confer indisputable advantages also in many other directions. It should not be forgotten, moreover, that the acquirement of a fresh source of water-supply for the metropolis would mean not only a purer water for drinking purposes but a supplementary supply for ultimate discharge into the river which would augment the volume flowing to the sea and necessarily tend to keep it in a less contaminated condition. The subject has been approached recently by Dr. W. Scott Tebb, the public analyst of the metropolitan borough of Southwark, who, in a paper that has reached us, concludes:—

> 1. That five out of the seven commissions or committees of inquiry which have investigated the quality of the Thames water have condemned the river as a source of domestic supply to the metropolis.
> 2. That the quality of the water as indicated by the analyses has shown no substantial improvement during the last 30 years.
> 3. That the river and its tributaries are at the present time extensively polluted by sewage, sewage effluents, foul house refuse, and other obnoxious matters.
> 4. That it is doubtful if this excessive pollution can ever be prevented, especially in times of flood, from gaining access to the river.
> 5. That there is no reason to suppose that the poison of cholera or typhoid can be eliminated from drinking-water by any practicable process of purification such as filtration.

Serious as are these conclusions they are made all the more serious by the contemplation that the water areas of England and Wales are likely to be acquired by local provincial towns and that therefore year by year the prospect of gaining a new and adequate source of water-supply for London becomes less certain.

HOLIDAYS AND THE INFLUENCE OF SEASON.

WHEN the question of holidays is being discussed and where to spend them concern is commonly expressed as to whether the prospective place is bracing or relaxing. Other questions, as, for example, water-supply, drainage, and so forth, are apparently regarded as minor points compared with climatological considerations. It will be found as a rule that it is seldom that a consensus of opinion is gained as to what really is the climatological characteristic of a given place. Some will say that X—— is bracing and others that it is relaxing. One man goes to the west of England because he finds it bracing and another avoids it because he is sure it is relaxing and not the place for a "run-down" constitution; "the east coast is the only place for him." The fact is that the question of whether a place is relaxing or bracing depends largely upon the meteorological conditions which exist at the time when the holiday is taken. There are certain meteorological conditions which are more or less constant, as, for example, those arising from the nature of the subsoil, the trend of the country, or the level of the place. Such conditions, it may be presumed, exert a practically unchanging influence on the health, although these conditions may be profoundly modified by excessive rainfall or by the prevalence of wind. Rainfall is a fairly constant quantity in different health resorts; thus on the east coast it is relatively dry and on the west relatively wet. But we cannot reckon upon the wind in a similar way, for it is an ever variable factor: it may blow "great guns," it may hardly be present at all, and it may set in from any point of the compass. The direction of the wind has probably the greatest disturbing influence on the regular climate of a place and this accounts for the differences of opinion that are often expressed as to whether a health resort is bracing or relaxing. The fact is that it may be both. A warm westerly wind may easily prove relaxing even on the proverbially bracing east coast and conversely a stiff easterly or northerly wind on the west coast will soon wipe away any reproach as to its soft or relaxing character. When the force of the wind is tempered by a local barrier, such as mountains, its exhilarating character is, of course, diminished. The question, therefore, whether a health station is bracing or relaxing is largely decided by the direction and the prevalence of the wind, the climatological conditions varying as the wind blows from south, east, north, or west. It is chiefly when wind is absent altogether that local conditions exert their influence. The man who seeks invigoration and health will do well to avoid those places in which there is a tendency of the air to stagnate. He should be in a constant stream of pure air. Hippocrates in his 24 aphorisms gives evidence of his knowledge of the influence of season and amongst other things attributes to the various winds the following qualities. The south wind, he says, dulls the sense of hearing and sight, and causes headache, heaviness, and faintness; the north wind affects the chest and the throat, and causes constipation and dysuria. The south wind relaxes and the north wind contracts the tissues of the body. Again, "continued northerly winds brace and strengthen the body, make it agile, fresh-coloured, and quick of hearing. This wind restrains the bowels, increases pains in the chest, and offends the eyes. Southerly winds relax and moisten the body, dull the senses of hearing and sight, and cause heaviness, vertigo, laziness, and diarrhœa." To the question, then: Is a place relaxing or bracing? the logical answer would appear to be: It depends largely upon the direction and the prevalence of the wind, for the local influences of level, subsoil, and topographical surroundings may be much affected by this factor.

FAMILY DEGENERATION OF THE CORNEA.

IN the *Ophthalmoscope* for May Mr. Robert W. Doyne and Mr. Sydney Stephenson have described a remarkable series of cases of degeneration of the cornea which occurred in one family. The first patient was a boy, aged 12 years, who said that his eyes had been subject to periodical attacks of inflammation for about 12 months. The right cornea was more or less nebulous with curious-looking calcareous streaks and particles at the junction of the lower and middle third. The appearances suggested a transverse *calcareous film* at an early stage of development. There was a very faint more or less generalised opacity of the left cornea. But annual thousands and out-patients by tens of thousands it is almost impossible to appreciate sufficiently the sum of its social work. A fuller conception of this side of hospital life should inevitably increase the sense of personal responsibility that rests upon all hospital workers—medical staff, students, and nurses.

The Social Instinct.

IN nearly every association which aims, directly or indirectly, at the improvement of its members, the social instinct is one which cannot be ignored. Associations may be formed for numerous purposes and they may have annual gatherings for the discussion of questions relating to the advancement of science or for the better regulation of matters concerning the ethical relations of their members but they succeed or they fail in direct proportion to the amount of friendly feeling which they encourage. This fact has lately been brought into prominence in the Presidential Address at the fifty-sixth annual session of the American Medical Association. The president, Dr. LEWIS S. MCMURTRY, discussed the origin, progress, and purpose of the Association and after reference to the annual gathering for the advancement of medical science and the elevation of the medical profession he spoke of the desire for improvement, for the increase of scientific resources and for the diffusion of medical knowledge which was evinced by every large gathering. Then came his happy remark upon the "social instinct" of our profession, "which would elevate and be elevated by interchange of views resulting from common experiences and by mingling together in pleasant friendly intercourse." The American Medical Association evidently labours under great disadvantages from the enormous area of the scope of its operations and it has struggled through the well-known difficulties of organisation as "a representative body composed of delegates from affiliated societies, colleges, and hospitals throughout the States." That the Association has grown and prospered during the half-century of its existence is shown by the proud statement that it is now the "largest medical organisation in the world." "It owns valuable property, has accumulated a considerable fund, and has a large annual income, all of which belongs to, and is subject to the control of, the members who, through their delegates, select the board of trustees to manage their funds." This is as satisfactory as can be desired but still the influence of the social instinct cannot be overlooked since this factor probably underlies many of the first beginnings of coöperation and association. At the annual gatherings matters of high moment may be discussed but at the ordinary meetings of the separate component parts of an association it may be doubted whether much interest is taken in medical politics, or even in the serious contributions to the advancement of medical science, for which outside help is so often desired. Local branches might almost be regarded as the separate constituencies which have the special function of electing delegates or representatives, who in turn have various important medico-political functions to perform. The local branches, however, would not long continue in existence if this remained their sole *raison d'être*. The members comprising local branches are not universally impelled by the ardent desire to advance science, either by their own contributions or by forming a receptive audience for the information to be derived from without. To explain their continued vitality we have to look for another mainspring and this appears to have been supplied by the reference to the "social instinct of our profession." There can be no doubt that social gatherings work for the ultimate good of all concerned. In nearly every district the struggle of competition is so great that relationships are liable to be strained and little misunderstandings are of frequent occurrence. It cannot be said that the public is innocent in the matter, since whenever medical topics arise some unfortunate yarn is apt to be told to the detriment of some practitioner and considerable self-restraint is frequently needed to prevent an abrupt challenge of an assertion or a demand for corroborative details. Libellous stories and injurious innuendoes may rankle so long as there are no opportunities for getting at the truth and many lamentable misunderstandings may be developed in the absence of some friendly common ground of meeting. Medical men who have the social instinct will probably discuss their little differences in an amicable fashion if they have the opportunity of meeting without the formality of a call demanding an explanation, and it is probable that by mingling "in pleasant friendly intercourse" not only are the mole-hills prevented from being made into mountains but they are perhaps smoothed away. Good fellowship is an essential in every association and it can be fostered by mutual knowledge.

At the annual meetings of the British Medical Association the social side is by no means the least conspicuous part of the gathering, and our columns this week recount many social meetings at which good fellowship was a prominent feature. This season of the year, when many medical men are taking a holiday, is one which is prone to give rise to difficulties in the matter of the treatment of one man's patient by a neighbouring practitioner. Occasionally it happens that when the holiday-maker returns his brother in the profession forgets to write or to mention that he has been called in as a substitute. If in such circumstances the two practitioners could meet at a dinner or some other social gathering it might be the means of promoting that *entente cordiale* which, desirable in every profession, is especially so amongst medical men.

Annotations.

"Ne quid nimis."

HAS THE TIME COME WHEN THE THAMES SHOULD BE ABANDONED AS A SOURCE OF WATER-SUPPLY?

No one can hold for a moment that the Thames is an ideal source of water-supply but it is a very grave indictment to say that the water at its best is diluted sewage. It is against the highest conceptions of public health that a river which serves as the channel for conveying the sewage of the metropolis away out of sight should be also the source of most of the water supplied to the metropolis for drinking purposes. It is, again, manifestly absurd that although the greatest precautions are taken to purify the water for such purposes yet a very large quantity of this purified water is used to carry away the dejecta of the consumer. And matters are not likely to grow better, for the population is increasing, which means that while more water will be wanted the output of sewage will be greatly increased. The introduction of bacteriological processes for the disposal and complete destruction of sewage, it is true, promised results compatible with hygienic requirements; but, remarkably efficient in breaking down putrescible matters as the bacterial agencies appear to be, we have it on the greatest authority that there is no decisive evidence that these agencies will destroy pathogenic entities. It is admitted that London water drinkers are at the mercy of the filter-beds. If these should fail the chances of the outbreak of disease are great and a water-borne disease in London would be too terrible to contemplate, threatening the lives not of thousands but of millions. The evidence, however, that the water-supply of London has been accountable for disease is not convincing and we are not aware that any difference has been shown to exist as regards the prevalence of disease between those who drink water derived from the Thames and those who drink, say, the deep well waters of the Kent division supply. It may be that some day it will be possible to draw a sharp line of demarcation between the two sets of water drinkers by the fact of water-borne disease breaking out in one or the other, but it is devoutly to be hoped not. At all events there can be little doubt that the abandonment of a supply derived from a river which is admittedly used for the carriage of sewage in favour of the adoption of a supply from the pure and abundant watershed of Wales would inspire a feeling of considerable confidence amongst London water drinkers and would confer indisputable advantages also in many other directions. It should not be forgotten, moreover, that the acquirement of a fresh source of water-supply for the metropolis would mean not only a purer water for drinking purposes but a supplementary supply for ultimate discharge into the river which would augment the volume flowing to the sea and necessarily tend to keep it in a less contaminated condition. The subject has been approached recently by Dr. W. Scott Tebb, the public analyst of the metropolitan borough of Southwark, who, in a paper that has reached us, concludes:—

1. That five out of the seven commissions or committees of inquiry which have investigated the quality of the Thames water have condemned the river as a source of domestic supply to the metropolis.

2. That the quality of the water as indicated by the analyses has shown no substantial improvement during the last 30 years.

3. That the river and its tributaries are at the present time extensively polluted by sewage, sewage effluents, foul house refuse, and other obnoxious matters.

4. That it is doubtful if this excessive pollution can ever be prevented, especially in times of flood, from gaining access to the river.

5. That there is no reason to suppose that the poison of cholera or typhoid can be eliminated from drinking-water by any practicable process of purification such as filtration.

Serious as are these conclusions they are made all the more serious by the contemplation that the water areas of England and Wales are likely to be acquired by local provincial towns and that therefore year by year the prospect of gaining a new and adequate source of water-supply for London becomes less certain.

HOLIDAYS AND THE INFLUENCE OF SEASON.

WHEN the question of holidays is being discussed and where to spend them concern is commonly expressed as to whether the prospective place is bracing or relaxing. Other questions, as, for example, water-supply, drainage, and so forth, are apparently regarded as minor points compared with climatological considerations. It will be found as a rule that it is seldom that a consensus of opinion is gained as to what really is the climatological characteristic of a given place. Some will say that X—— is bracing and others that it is relaxing. One man goes to the west of England because he finds it bracing and another avoids it because he is sure it is relaxing and not the place for a "run-down" constitution; "the east coast is the only place for him." The fact is that the question of whether a place is relaxing or bracing depends largely upon the meteorological conditions which exist at the time when the holiday is taken. There are certain meteorological conditions which are more or less constant, as, for example, those arising from the nature of the subsoil, the trend of the country, or the level of the place. Such conditions, it may be presumed, exert a practically unchanging influence on the health, although these conditions may be profoundly modified by excessive rainfall or by the prevalence of wind. Rainfall is a fairly constant quantity in different health resorts; thus on the east coast it is relatively dry and on the west relatively wet. But we cannot reckon upon the wind in a similar way, for it is an ever variable factor: it may blow "great guns," it may hardly be present at all, and it may set in from any point of the compass. The direction of the wind has probably the greatest disturbing influence on the regular climate of a place and this accounts for the differences of opinion that are often expressed as to whether a health resort is bracing or relaxing. The fact is that it may be both. A warm westerly wind may easily prove relaxing even on the proverbially bracing east coast and conversely a stiff easterly or northerly wind on the west coast will soon wipe away any reproach as to its soft or relaxing character. When the force of the wind is tempered by a local barrier, such as mountains, its exhilarating character is, of course, diminished. The question, therefore, whether a health station is bracing or relaxing is largely decided by the direction and the prevalence of the wind, the climatological conditions varying as the wind blows from south, east, north, or west. It is chiefly when wind is absent altogether that local conditions exert their influence. The man who seeks invigoration and health will do well to avoid those places in which there is a tendency of the air to stagnate. He should be in a constant stream of pure air. Hippocrates in his 24 aphorisms gives evidence of his knowledge of the influence of season and amongst other things attributes to the various winds the following qualities. The south wind, he says, dulls the sense of hearing and sight, and causes headache, heaviness, and faintness; the north wind affects the chest and the throat, and causes constipation and dysuria. The south wind relaxes and the north wind contracts the tissues of the body. Again, "continued northerly winds brace and strengthen the body, make it agile, fresh-coloured, and quick of hearing. This wind restrains the bowels, increases pains in the chest, and offends the eyes. Southerly winds relax and moisten the body, dull the senses of hearing and sight, and cause heaviness, vertigo, laziness, and diarrhœa." To the question, then: Is a place relaxing or bracing? the logical answer would appear to be: It depends largely upon the direction and the prevalence of the wind, for the local influences of level, subsoil, and topographical surroundings may be much affected by this factor.

FAMILY DEGENERATION OF THE CORNEA.

IN the *Ophthalmoscope* for May Mr. Robert W. Doyne and Mr. Sydney Stephenson have described a remarkable series of cases of degeneration of the cornea which occurred in one family. The first patient was a boy, aged 12 years, who said that his eyes had been subject to periodical attacks of inflammation for about 12 months. The right cornea was more or less nebulous with curious-looking calcareous streaks and particles at the junction of the lower and middle third. The appearances suggested a transverse calcareous film at an early stage of development. There was a very faint more or less generalised opacity of the left cornea. But the most striking opacity was a tongue-like process extending across the cornea for three-fourths of its area. The patient's father was a working carpenter, aged 48 years. At the age of 30 he suffered from "ulcers" of the left eye and after 12 months the sight was lost. He denied having had syphilis. The right eye was divergent and the central part of the cornea was covered with dense, whitish-grey, calcareous-looking particles so that the pupil was entirely hidden. The mother of this man suffered from "bad eyes" from youth and in adult life her sight was so poor that she had to be led about. She died at the age of 65 years. The remaining members of this generation included three sisters and one brother, of whom one sister suffered in a similar way. The carpenter had eight children. Of these, four, including the boy whose case was first described, were affected. One, a daughter, aged 24 years, began to suffer at the age of 16 or 17 years. On examination the corneæ were found cloudy but presented no signs of inflammation. But for certain facts the case might have passed for interstitial keratitis. In the right eye the iris could be only dimly seen through the milky cornea. The left cornea was still more opaque and the nebula showed a lattice-like arrangement, especially towards the centre. The second patient was a daughter, aged 22 years, whose eyes began to fail between the ages of 16 and 18 years. The corneæ were so milky that only indications of the underlying parts could be made out. The third patient was a girl, aged 15 years, whose eyes became affected at the age of seven. The sight became progressively worse without any symptoms of inflammation. The condition of the corneæ resembled that of the last patient but was not quite so bad. Thus in this family there occurred in three generations seven cases of bilateral slowly progressing degeneration of the cornea leading after several years to serious loss of sight. As a rule, there were no symptoms of inflammation. When there were they probably were due to erosions of the corneal epithelium which, as the result of the degenerative changes, was specially vulnerable. There was no evidence of syphilis nor were the parents consanguineous in either generation. Family degeneration of the cornea, though rare, is by no means unknown to systematic writers. Haab reported a case of what he called "lattice-like keratitis" in a boy, aged 16 years, whose maternal aunt and uncle were also affected. Dimmer recorded three cases of superficial lattice-like opacity of the cornea in two brothers and a sister, aged respectively 55, 49, and 51 years. Freund of Reichenberg in Bohemia has described seven cases in one family and eight in another which he traced through four generations. In this country Mr. R. Marcus Gunn has reported four cases of "keratitis nodosa" in a family and Mr. W. T. Holmes Spicer "nodular opacities" of the corneæ in a father and daughter. These conditions appeared to be examples of the disease now under consideration.

POST-GRADUATE STUDY AT THE UNIVERSITY OF CAMBRIDGE.

AT the commencement of the present long vacation—namely, in the beginning of July—a course of instruction for senior students, medical men, and veterinary surgeons, lasting for about four weeks, was opened in the medical school of the University of Cambridge. This course included (1) lectures and demonstrations on protozoa and protozoal diseases, by Dr. G. H. F. Nuttall; (2) lectures and demonstrations on pharmacology, by Mr. W. E. Dixon; and (3) lectures and demonstrations on general and special pathology, by Professor G. Sims Woodhead, Dr. H. E. Durham, Dr. W. Malden, and Dr. G. S. Graham-Smith. The protozoal diseases which were treated of included amœbic dysentery, trypanosomiasis, sleeping sickness, kala-azar, coccidiosis, and malaria. The subjects of the pathological lectures and demonstrations comprised phagocytosis, Dr. A. E. Wright's "opsonins," toxins and antitoxins, venins and antivenins; methods of standardisation, the iodophil reaction in blood, illness due to unsound foods, diphtheria, agglutinins and agglutination methods, precipitins, and hæmolysins.

THE SODIUM SALTS OF THE COUMARIC ACIDS AS THERAPEUTIC AGENTS.

THE hypodermic application of sodium cinnamate in aqueous solutions (hetol) or dissolved in glycerine, which was referred to in a paper by Mr. Gilbert T. Morgan, D.Sc., F.I.C., in THE LANCET of July 12th, 1902, p. 66, still continues to receive considerable attention and among the more recent developments of the treatment based on the use of this therapeutic agent may be mentioned the serum obtained by the firm of Kalle and Co. of Biebrich-am-Rhein from tuberculous horses after repeated injections of the cinnamate. In a recent communication Dr. Morgan points out the interest bearing on the connexion between the chemical structure of cinnamic acid and its physiological action owing to the discovery that phenylpropiolic acid in the form of an aqueous solution of its sodium salt (thermiol) also has a marked action in the development of leucocytosis and can likewise be applied to the treatment of tuberculosis. Both these acids contain an unsaturated carbon chain attached to a benzene nucleus, the former acid having a double linking and the latter a treble bond. Since these substances are far more active physiologically than benzoic acid, $C_6H_5.CO_2H$, which does not contain the unsaturated group it may be assumed as a working hypothesis that this action is in some way connected with the presence in the molecule of the double or treble linking, this junction being known to be a point of great chemical reactivity. In the course of a series of clinical investigations carried out by Dr. G. Lovell Drage with the glycerinum sodii cinnamatis a demand arose for a drug having a more pronounced action and Dr. Morgan was thereby led to consider in what way the physiological activity of cinnamic acid might be enhanced. The employment of benzene derivatives as therapeutic agents has amply demonstrated the fact that the presence of an amino- (NH_2) or a hydroxy- (OH) group in the aromatic nucleus greatly increases the physiological action of the parent hydrocarbon and it therefore seemed likely that the use of a substituted cinnamic acid containing one of these groups might bring about the desired effect. Since the employment of amino-compounds of the antifebrin type is often attended by unpleasant secondary effects a hydroxy derivative was selected in the first place—namely, sodium ortho-coumarate, a substance having the structure of cinnamic acid with a hydroxyl (OH) substituent. Ortho-coumaric acid is somewhat similar in constitution to salicylic acid, these two acids standing in the same relationship to each other that cinnamic acid does to benzoic acid. This likeness to salicylic acid was also a determining factor in the choice of ortho-coumaric acid for medicinal purposes, bearing in mind the beneficial action of the salicylates in certain pathological conditions. For hypodermic injections a 22 per cent. aqueous solution of the sodium ortho-coumarate is prepared containing a slight excess of the free ortho-coumaric acid. The dichroic solution is quite limpid and stable, and as the salt is extremely soluble in cold water even a higher concentration may be employed if necessary. In all the cases hitherto studied the solution has induced a rapid physiological action, the leucocytosis being well marked and resembling that effected by the cinnamate. Experiments have also been instituted on the sodium salts of the two isomeric coumaric acids with the view of ascertaining whether the change in the relative positions of the active groups brings about any appreciable differences in their physiological effect. Sodium para-coumarate, prepared by the Perkin-Fittig synthesis from para-hydroxy-benzaldehyde, is a much less soluble salt than the ortho-compound and accordingly an 8 per cent. aqueous solution was employed. The results obtained with equivalent quantities seemed to show that the action was of a similar nature but rather less intense than that produced by the ortho-salt. Sodium meta-coumarate, which was employed in 20 per cent. aqueous solution, had a very marked physiological action, being apparently even more active than the ortho-compound. The meta-coumaric acid required for this preparation was produced synthetically from meta-nitrobenz aldehyde. From a chemical point of view the action of the meta-acid is of special interest. It is well known that benzenoid ortho- and para-compounds in general often resemble one another in their chemical and physical properties whereas they frequently both differ markedly from their isomerides of the meta-series. In the case of the ortho- and para-coumaric acids the groups (OH) and (CH : CH . CO$_2$H) are in sympathetic positions and might accordingly be supposed to act conjointly but in the meta-compound these groups are in apathetic positions with respect to each other, so that the meta-acid might be expected to exhibit the dual properties of phenol and cinnamic acid, each substituent group producing its physiological effect to some extent independently. The three isomeric coumaric acids are certainly physiologically active but it must be left for further experiments to decide which of these is likely to prove to be the most serviceable therapeutic agent. The investigation is being extended to other compounds of a similar type and Dr. Morgan may be congratulated on the prospect opened up of being able possibly to correlate the physiological action of these substances with their chemical constitution.

A QUESTION OF ACCIDENT OR DESIGN.

At Swansea an action has been tried recently by Mr. Justice Channell in which so remarkable a story was suggested on the part of the defence that it deserves to be recorded. The jury were unable to agree as to what had actually occurred and therefore, as the case may be tried again, comment would be out of place. The plaintiff sued for damages for the loss of both his legs, alleged to have been caused by the negligence of the defendants, the Taff Vale Railway Company. His story was that when travelling in a second-class carriage on the defendants' line he rose from his seat in order to place his umbrella in the rack. At that moment a jolt occurred which threw him against one of the doors and this being left unfastened permitted him to fall out upon the line where he somehow got into such a position that the train he had travelled in went over his legs, with the result that they had to be amputated. Presumably the negligence relied upon consisted in the door being open, not in the jolting, which must be natural to railway travelling and can hardly be sufficient to found an action for damages upon when a very unlooked-for result occurs. The railway company, however, denied that any jolting occurred at the place indicated, and incidentally further denied that the plaintiff was in the train at all. They called evidence to show that he was not one of the second-class passengers on the evening in question and said that he might easily have bought the ticket found on him and have walked along the line without being seen. They suggested that he actually did this and laid his legs across the line in order to secure compensation for the terrible injuries which must necessarily ensue. He had upon him when found copies of three papers which provide insurance coupons for their readers and had written his name on these. Under the terms of these coupons, however, it was pointed out, he would not be entitled to recover except in respect of an accident happening to the train itself in which he travelled and consequently, unless he had omitted to study the conditions laid down, the fact that he was thus insured could have no bearing on his conduct. The strongest evidence on behalf of the defendants was that of three medical witnesses, all of whom had seen him within various short periods after the accident, including one gentleman who saw him before his removal to the Cardiff Infirmary. Their testimony, briefly, was to the effect that they would have expected in the case of an accident such as the plaintiff described to find other serious injuries in addition to those to the legs, which, however, they had not done. Each leg, moreover, was crushed practically at the same point, so that at the time when the train passed he must have been lying with them crossing the nearest line at right angles, which medical witnesses considered to be an unlikely position in the alleged circumstances of accidental falling from the train. The first jury to hear the case has separated after vainly trying to come to an agreement upon the subject and it will be interesting to see whether a verdict is ultimately arrived at.

THE CLIMATE AND THERAPEUTIC INDICATIONS OF MEXICO.

In a Consular Report of Mexico just published the statistical department of the Superior Board of Health gives some interesting records of the mortality from various diseases. In the city of Mexico diarrhœa in its various forms heads the list, with a total of 3720, nearly two-thirds of this number being children. Then come the diseases of the respiratory organs: pneumonia, 1229; pulmonary tuberculosis, 1125; bronchitis, 1002; and broncho-pneumonia, 688; making a grand total of 4044. Some of the other causes of death mentioned in the report of the Board of Health are as follows: organic diseases of the heart, 610; meningitis, 485; cerebral congestion and hæmorrhages, 365; infantile complaints, 473; cirrhosis of the liver, 631; other diseases of the liver, 320: diseases of the intestines and stomach, 257; accidents, 311; convulsions of children, 182; alcoholism, 194: typhus fever, 248; malaria, 102; measles, 97; scarlet fever, 33; and diphtheria, 42. The general idea of the Mexican climate (which in reality is a very varied one) leads us to expect a heavy mortality from diarrhœa and malarial conditions but it is rather surprising to note the high figure in respect of diseases of the respiratory organs. It may be partly accounted for, no doubt, by the number of visitors suffering from pulmonary tuberculosis who seek the climate of the higher table-lands in the hope of cure. The line of treatment adopted by the physicians is much the same as in other places—open air, good food, and abundance of sunshine being the chief methods employed. It is noticed, however, in the report that people, especially newcomers, in the high latitudes (Mexico city is 7500 feet above the sea) are particularly liable to catch "colds" and to find great difficulty in getting rid of them. The more experienced residents adopt the plan, directly they feel the symptoms of a cold, of leaving the city for Cuernavaca, Cuautla, Orizaba, Vera Cruz, and other places and find that on a lower level they very soon recover. It is difficult for the public to realise the effect of genuinely high altitudes on the breathing apparatus. The highest part of London (Hampstead Heath) is only about 360 feet above the sea-level and on the banks of the Thames, where thousands of London working men and their families congregate, the height above the sea is about 22 feet. The table-lands of Mexico vary from 5000 to 7000 feet above the sea, but when we have reached the summit of Snowdon (where no one lives) we have only attained an altitude of 3560 feet. Visitors to Mexico are recommended to wrap themselves up well before going out in the evenings, for even in a climate where all the products of the vegetable kingdom grow with luxuriant ease the night-air is liable to sudden changes and disease comes swiftly. One of the best protections against it is to maintain the general system by taking plenty of nourishing food, especially in the dry season, which is the most dangerous of the whole year. Tuberculosis, diarrhœa, and enteritis are said to be chiefly rife among the very poor. And, indeed, when we learn the primitive nature of the housing accommodation—the working classes for the most part being content with one room where the door does duty for both window and chimney and where neither water nor any sanitary arrangement exists—this is not surprising. Applying their habitations as a standard to the rest of the lives of the poor of Mexico it is no wonder that the officials of the Superior Board of Health and other physicians of the city state that the principal causes of the high rate of mortality are "bad food, bad water, and excessive drinking of pulque." "Pulque" is the national drink made from the juice of the agave or Mexican aloe, the vine of the ancient Aztecs. This plant grows in various forms very freely all over Mexico, and besides the juice, which is said to have been the ruin of many Indian tribes as well as of the white inhabitants of the country, large quantities of fibre used in the manufacture of twine, rope, and so on, are obtained from it. The best time to visit Mexico is in the winter months between September and March on account of the stringent quarantine regulations in the United States and Cuba. In this season the hurricanes which rage along the coast make the neighbourhood a terror to navigators but these same winds sweep the lower lands sloping down to the sea free from malaria and yellow fever which prevail in the hot season.

TREATMENT OF TUBERCULOUS ADENITIS BY THE X RAYS

IN *La Polyclinique* (Brussels) of June 15th M. Hendrix has published some very encouraging results from treatment of tuberculous adenitis with the x rays. A man, aged 50 years, had had for a year in the left supraclavicular fossa a tumour of the size of the fist consisting of an agglomeration of enlarged glands. It was fixed in its deep part but the skin was moveable over it and unaltered. It pressed on the brachial plexus, producing paresis and slight atrophy of the arm and hypoæsthesia of the fingers. The patient was in the early stages of tabes dorsalis and of tuberculosis of the apices of the lungs. Treatment with the x rays was commenced on May 25th, 1903, and was continued for three months. After the first application the glandular mass began to diminish. On August 22nd an unexplained phenomenon occurred: the tumour underwent a sort of gaseous degeneration. There was a sensation of crepitation and percussion gave a tympanitic note. On the following day this phenomenon had disappeared; there was no further trace of the tumour and the symptoms due to compression of the brachial plexus had disappeared. At the time of the report, two years later, the only trace of the tumour was a hard lump of the size of a small almond. The tabes dorsalis and the pulmonary tuberculosis persisted. In a second case the patient, a boy aged nine years, was seen on April 1st, 1905, with a large glandular mass extending along the right sterno-mastoid muscle from the mastoid process to the clavicle and penetrating so deeply that its lower limit could not be defined. It was multilobular and somewhat soft but the glands which composed it were hard and elastic. It was fixed to the deeper parts but the overlying skin was sound and moveable. After three days' treatment the result was surprising: the mass had disappeared and the glands could be rolled on one another. The latter diminished and after four weeks there was only one enlarged gland of the size of a hazel-nut. Eleven days later this had disappeared. In a third case the patient, a girl aged 18 years, had had for three years four enlarged glands varying in size from a hazel-nut to a large chestnut. They were hard and elastic, moveable, and without inflammatory reaction. The largest was situated at the angle of the jaw and was formed of conglomerated glands. Injection of tuberculin gave a positive result. Treatment with the x rays was begun eight days before the time of the report when the glands had already diminished. M. Hendrix finds that the action of the x rays is most rapid in cases when the glands are agglomerated into a mass. As illustrated above, the connecting material disappears in a few days and the glands can be rolled on one another. In a few weeks these diminish without altering in consistence. Then the smaller ones disappear entirely; the larger ones sometimes leave a sclerous nodule, a kind of cicatricial residue. M. Hendrix has never observed a relapse.

THE CHILDREN'S COUNTRY HOLIDAYS FUND.

THE Bishop of London sends us an appeal on behalf of the Children's Country Holidays Fund, an institution which is doing a work of far-reaching importance, inasmuch as the health of the poor children of London has a significant bearing on the physical well-being of the future toilers of our great metropolis. As his lordship points out, the poor children of London are unlike more fortunate boys and girls to whom the end of the school term brings days of health and enjoyment in the country or at the seaside, for the great majority of the 800,000 children in our London elementary schools spend their month of leisure in stuffy and overcrowded rooms or at play on glaring asphalt pavements. Even those who are strong are overcome by lassitude, while the delicate suffer terribly from the intense heat and the unceasing roar of traffic. To the poorest among these children the Children's Country Holidays Fund presents the opportunity of spending a fortnight amid country scenes with country hosts. Last year the public enabled the fund to send away over 39,000 children; this year still more are asking for the holiday. There are over 18,000 children waiting to go on August 10th and to pay for them the fund requires another £5000. The offices of the fund are at 18, Buckingham-street, Strand, W.C., the honorary treasurer is the Earl of Arran, and £1 1s. will send away two children for a fortnight. Few will fail to realise the good work which this fund is doing and we trust that the appeal will be liberally responded to

SENILE ALBUMINURIA.

THE *Boston Medical and Surgical Journal* of July 13th contains an important paper by Dr. A. E. Austin on a condition which is not generally recognised—senile albuminuria. In a paper with the paradoxical title, "The Advantages of a Trace of Albumin and a Few Tube Casts in the Urine of Certain Men above 50 Years of Age," which was noticed in our columns,[1] Professor W. Osler has described a form of albuminuria which he attributed to "pre-senile changes in the kidney the result of arterial degeneration causing a circulatory disturbance in the kidney." Dr. Austin in examining the urine of the aged paid attention to the form of albumin present, for the prevailing prostatic enlargement and consequent irritation cause nucleo albumin and mucin to be present. The former on account of its solubility in strong acids cannot be mistaken for serum albumin in the cold nitric acid test but the latter forms a clear zone which, however, is at some distance from the acid. Dr. Austin always verified the presence of serum albumin by cooking with acid phosphate of sodium. He examined the urines of 45 men of ages varying from 64 to 95 years, the greater number being over 70 years. In 16 mucin alone was present as shown by the formation of "an upper ring." Of these 16 cases prostatic and seminal vesicle cells, amyloid bodies, and a few pus cells and blood corpuscles were present in nine, pelvic and renal cells and hyaline were present in one, and no concomitant condition could be discovered in four. In nine cases a typical ring showing only serum albumin was present. The amount varied from a mere trace to ½ per cent. in one case and ¼ per cent. in another. Associated with it in four cases were discrete pus corpuscles, much blood, and bladder and prostatic cells but no casts; in two cases pus, pelvic cells, and blood corpuscles were found in clumps: in three cases there were hyaline and granular casts. Thus three conditions could be distinguished—prostatic catarrh, mild pyelitis, and pyelonephritis. In ten cases both serum albumin and mucin were found; in most of these cases casts were found as well as the other bladder and prostatic cells. Thus the urine of 19 out of 45 old men contained albumin varying in amount from traces to considerable quantities. Yet these men were not ill and suffered only from the infirmities of age. Dr. Austin concludes that albuminuria is fairly frequent in old men, that mucinuria is more so, that both are associated with changes in the urinary tract and that these changes are not of serious import. These facts are important because in ignorance of them the practitioner might readily diagnose Bright's disease and give a prognosis and follow a treatment not applicable to the case.

---

[1] THE LANCET, Dec. 14th, 1901, p. 1590.

A CHECK UPON THE DISSEMINATION OF PULMONARY TUBERCULOSIS.

EVIDENCE is forthcoming that the Local Government Board is now seriously considering the spread of pulmonary tuberculosis among the poorer classes of society. It will be remembered that in April last a deputation of persons interested in the prophylaxis of this disease waited upon the Metropolitan Asylums Board to urge the advisability of the Board's undertaking the provision of sanatoriums. The managers of this Board, having asked for the views of the Local Government Board, have been informed that the latter body is obtaining information on the subject but is not yet in a position to express an opinion as to whether the managers should undertake the new duties suggested by the deputation. A communication addressed on July 3rd to the clerk to the Bath union shows, however, that the Local Government Board is moving to some extent in the direction desired by the memorialists, for it has decided that indoor paupers suffering from pulmonary tuberculosis with expectoration may be regarded as afflicted with an infectious disease within the meaning of Section 22 of the Poor-law Amendment Act, 1867, and may therefore be detained in a workhouse on a certificate by the workhouse medical officer until that officer shall furnish a further certificate to the effect that the patient can be discharged without danger to himself or to others. Much depends on the interpretation of this decision which medical officers accept as their guide but if compulsory detention is adopted in all the cases in which it would clearly be to the advantage of the patient and of those connected with him some special provision in the shape of infirmaries or sanatoriums will be rendered necessary.

THE Alvarenga Prize of the College of Physicians, Philadelphia, has been awarded to Dr. D. Chalmers Watson, Edinburgh, for an essay on "The Importance of Diet: an Experimental Study from a New Standpoint."

SIR Joseph Walton, one of His Majesty's Justices of the Supreme Court, has accepted the presidency of the Medico-Legal Society, in succession to Sir William J. Collins, the first President.

A VISIT TO JAMAICA IN MARCH AND APRIL, 1905.

BY THOMAS W. THURSFIELD, M.D. ABERD., F.R.C.P. LOND.,

PHYSICIAN TO THE WARNEFORD HOSPITAL, LEAMINGTON.

WITH a view of bringing to the notice of the medical profession the capabilities and advantages of the island of Jamaica as a winter resort for invalids and tourists Sir Alfred Jones, the managing director of Elder, Dempster and Co., some 12 months ago announced that he was willing to take a number of medical practitioners for a voyage to Jamaica and back in one of the magnificent steamers of the New Imperial Direct Mail Steam Line to the West Indies. I was fortunate in receiving an invitation and the following rough notes are, as far as they go, a record of a most enjoyable episode.

We sailed from Avonmouth, Bristol, on March 25th at 8 A.M., my cabin companion being Dr. Sidney A. Bonner of Great Berkhamsted. The ship we sailed in, the *Port Kingston* (twin screw), is 7000 tons burden and 10,000 h.p., with a speed of over 17 knots and is considered to be the best of the whole of the fleet of steamers engaged in the service. Voyages are much the same wherever one goes, but having seen many ships and made many voyages I never sailed on a more comfortable or better found vessel. Of her cleanliness, ventilation, and sanitary arrangements I cannot speak too highly, while the service was efficient, punctual, and willing. I am sure that the passengers would all join in my testimony to the merits of Captain Parsons and his officers.

On the ninth day out, after sailing through all the glories of the tropics, we made our first land—Turk's Island, one of the Bahamas—and on the next afternoon we arrived at Port Royal, Jamaica, of old piratical and infamous reputation, reaching Kingston just before dark after a splendid voyage of 4250 miles in a little more than ten days. As is always the case in the tropics, darkness came on quickly and before the formalities of the Custom House were completed it was dark. But having hired a buggy we drove five miles through what appeared to be a well-lighted, very populous, and rather dilapidated town to a hotel called the Hotel of the Constant Spring. It is situated at the bottom of the foothills of the Blue Mountain range, 600 feet above the town and in a beautiful garden park. It is also the terminus of one branch of an electric tram service which serves Kingston in an efficient and cheap manner. The hotel is large and well arranged and is owned and managed by the Elder Dempster Company. The water-supply, as the name of the hotel suggests, is regular and abundant. There is a fine swimming bath attached to the hotel, through which runs a stream of water coming directly from the mountains. There are a fine garden and park with tennis lawns, a cricket ground, and a fair golf course. The views of the mountains in one direction and of the city and the sea in the other are most striking, and altogether the visitor could not be better housed. One peculiarity of the island of Jamaica is the regular occurrence of the sea breeze and the land breeze. The sea breeze in fine weather begins about 10 A.M. and gradually strengthens until by noon it is really strong in the town and harbour. By 4 or 5 o'clock it begins to die away and by 6 o'clock it ceases. Somewhere about 8 o'clock a faint but pleasant breeze in the exactly opposite quarter arises, blowing off the mountains and the land towards the sea. These winds to some extent determine the architectural arrangements of the better class houses of the island. Houses are so built that both winds may blow through them, and the comfort that this affords in a hot climate is considerable—in fact, except when one is making considerable efforts or taking violent exercise one need never feel too hot in Jamaica. The Hotel of the Constant Spring is arranged carefully to catch these breezes and though the thermometer was sometimes over 85° F. I never once felt too hot in its cool breezy public rooms and corridors. Shortly after my arrival I was asked with my brother (who is well known in Jamaica and who went there with me for his fourth visit to the island) to stay with his Excellency the Governor at the King's House. There I stayed for three days in much comfort, being free to use and enjoy one of the most perfect gardens I ever saw, in which I made acquaintance with all sorts of beautiful tropical plants and trees. Others have so fully and graphically described the flowers and the fruits of the tropics in general, and of Jamaica in particular, that I will not venture but I will give a general warning as to the consumption of fruit by visitors. Upon arrival they must be careful. The fruit is tempting to sight and taste and it is peculiarly so in a hot climate. Visitors should take it sparingly at first and in the morning rather than at any other time and should see that it is ripe and fresh.

The city of Kingston (about 35,000 inhabitants) is not beautiful as a city but in many ways it is interesting and there are many institutions in it well worth a visit. Locomotion is easy and cheap owing to the electric tram service. There is a good club to which visitors can belong upon easy terms if properly introduced. There is a small garrison of white troops, and, as a matter of course, the usual sports and games of our officers follow, such as races and polo. Kingston is the seat of government of the island and the centre of its commerce. The residences of the officials and of the commercial magnates are in and around the city and no words of mine can sufficiently acknowledge the unbounded hospitality I received everywhere in Jamaica but especially in Kingston. Everyone wished to do their utmost to please and to entertain and each one vied with the other until the guest was compelled to make a choice of being half-killed by kindness or of risking offence in the defence of his poor self.

Some days after my arrival I joined an expedition to Newcastle, a military station for the white troops about 4500 feet above the sea and in the Blue Mountains. We went partly by tram and partly in carriages, but for the greater part of the distance we rode ponies, and on our way we stopped to inspect a coffee plantation and saw the whole process from the flower to the dried seed or bean constituting the coffee bean of commerce. We were informed that the Blue Mountain coffee was the best in the world, but unhappily, like the famous British infantry, there is very little of it. I am told that this coffee is so good that very little gets into retail commerce in the pure state as it is used to bring up the quality of lower grades by being mixed with them. Be this as it may, I can say that the coffee prepared from it is very good indeed. The views from Newcastle are superb and the ride through the various forests is most interesting. As to the ponies they are marvellous; I am sure they could climb stairs and am not sure that ladders would be beyond their talents. We spent a long day among these mountains and got home by 8 P.M. The temperature at Newcastle was between 60° and 70° F. One of the officers in charge of this sanatorium for white troops described Newcastle as being a one blanket place in the summer and a two or three blanket place in the winter months.

Later I had a most delightful excursion to the other side of the island to a beautiful plantation called Cape Clear. We partly drove and partly walked and partly went by railway. We stuck in a river and had to get out and wade, but all our trouble was repaid by a most hospitable welcome at the hands of our friends on the plantation. There we met a picked assembly of some of the largest planters of the island and were introduced to the mysteries and methods of banana cultivation. Returning by rail to a station called Bog Walk we drove down a magnificent pass, one of the show drives of the island, along the Rio Cobre, a river which is made to operate the whole electric force of Kingston, whether for tramways or for lighting, and arrived at the ancient capital of the colony—Spanish Town. Here there are several objects of interest—among others a fine monument to Rodney, the saviour of the West Indies, a title earned by his victory over the French fleet under Admiral Comte de Grasse.

Jamaica as a health resort can start by boasting a good statistical record. The population of the island as estimated by the Government officials at the end of the year 1904 was 797,528. Of this number about 20,000 are supposed to be white. The death-rate for the whole island is low; in 1904 it was 24·2 per 1000 and in 1902-03 it was as low as 19·8. For the past ten years the island death-rate has averaged 21·45 per 1000. The death-rate of Kingston is higher, being 29·7 in 1903-04. The birth-rate of the whole island in the same year was 39·9 per 1000, a very satisfactory contrast to the death-rate. One of the principal causes of death is pulmonary tuberculosis, while the mortality from cancer is very small in comparison with our home statistics. I had the advantage of a long conversation with Dr. M. Grabham, one of the best known physicians in the colony, whose work upon the mosquitoes of Jamaica has brought him well-deserved recognition and fame. He told me that there were very few endemic diseases in the island and none to which visitors were usually liable supposing common precautions are taken. Simple continued fever after undue exposure or fatigue is readily met by rest and care; typhoid fever is not at all common; pulmonary tuberculosis is rather common but is nearly always of the acute type; dysentery is uncommon; yellow fever is very uncommon and always under complete control; and leprosy is rapidly declining. There is an island fever of a malarial type which attacks residents who have to live and work in swampy places; it is probably mosquito-borne but it is not severe when properly managed and is unknown at elevations above 2000 feet. The water-supply of Jamaica is good and plentiful but for drinking purposes water should always be boiled, especially at the beginning of the rainy season, unless its sources are absolutely guarded and cleansed, for there are many squatters in the hills, so that it is not easy to be absolutely sure of the purity of any supply. Kingston has a good water-supply and its drainage system is good, the effluent being carried right out to sea outside the coral reefs. From these facts and figures it will be gathered that Jamaica is a very healthy tropical country and that with due precautions it is eminently suited for the reception of visitors who may with very ordinary care enjoy a glorious climate, magnificent scenery, and new sensations with little or no risk to their own health, less, in fact, than they would run on the Riviera or in Egypt. As to climate, the general temperature during the best months of the year—namely, December, January, February, and March—is about 80° F. in the shade, cooling down some 5° to 7° in the night. It rarely reaches 90° and, except in the mountains, does not go below 75°. There are two rainy seasons, one in May and one in October, the latter being much the longest and most severe, but there are, as Jamaica is so mountainous, rain storms at all times. During my short visit I was never inconvenienced by the heat and never once kept awake by a hot night. In the middle of the day it is generally very hot and the heat of the sun is very striking but then one must remember the latitude of Jamaica, 17½° N., and take the usual tropical precautions.

And now as to the class of invalids who may be recommended to winter in Jamaica with advantage to their health. First, then, I should consider, and in this I am borne out by the local practitioners, that there are very few phthisical patients who would get any advantage whatever by a residence in Jamaica. The climate is too enervating for the majority of such cases and, moreover, the arrangements are more suited for strong and active people than for invalids who must take and receive every advantage they can get. I can conceive that in the very initial stage of picked cases much good might be done, but the place would only be suitable for a few months of the year. For advanced cases of pulmonary tuberculosis Jamaica is altogether unsuitable. This is almost indicated by the fact that pulmonary tuberculosis when it occurs in the native population generally progresses in a most rapid way. On the other hand, patients who suffer from bronchitis and winter cough and nearly all cases of chronic rheumatism are greatly benefited by a winter in Jamaica, while certain forms of kidney disease are much relieved. Rheumatism and kidney disease are very rare among the native-born inhabitants, white and black.

Jamaica is often spoken of by the inhabitants of the other West India islands and of Demerara as the very healthiest spot in the West Indies and it has been used for generations as the sanatorium for the other places, yet the neglect of common precautions at one time made this healthy spot into a white man's grave for the troops stationed there. Now the application of ordinary scientific laws and common-sense precautions has made Jamaica one of the healthiest of our foreign stations. The really frightful mortality which used to occur is gone and instead we have merely a low average death-rate, better a good deal than in some quarters held in much higher estimation as to health. Invalids and, indeed, anyone going to reside in Jamaica for even a short period should take certain precautions and avoid certain imprudences. As to clothing, it should be of the lightest wool or silk next the skin and the very lightest external clothes either flannel or cotton. The head should be well protected and a well-ventilated helmet of pith or other light material should be worn when much exposed to the sun. With light clothing and a well-protected head no one will be incommoded by the heat in Jamaica. As to diet, I have already mentioned that all newcomers to the tropics should be very careful of the fruit when first they arrive. It is cool, luscious, and tempting, but after a long voyage, during which the digestive organs may have been upset, it is very apt to disagree. It is well to eat sparingly of meat and rather to eat sparingly altogether upon first arrival. There are so many and such a variety of tempting dishes that this is rather a counsel of perfection but it is nevertheless a wise precaution. What to drink is a matter of taste and habit but I may record that the almost universal beverage beyond tea and coffee is whisky and soda-water with ice. The various fruits are compounded into most delicious iced squashes and I cannot but believe that the less alcohol consumed by anyone the more fit and healthy that person will be. It is not well for newcomers to expose themselves too much to the sun without protection but the absolute terror which some people have of this luminary is very amusing and very unreasonable; a white umbrella is useful and necessary indeed to those who either suffer from or fear the sun. True insolatio (heat apoplexy or real sunstroke) is practically unknown in the island and the commonest precautions will avert any evil consequences of exposure to the sun. It is as well to be careful in the evening of the land breeze, chills from this delicious wind while sitting at dinner being frequent. It is well to wear under evening clothes something round the loins like the woven apparatus that is called a cholera belt; this can be procured everywhere.

To sum up a panegyric, it seems to me that for anyone who has leisure and desires to see perhaps the most beautiful island in the tropics and at the same time by a pleasant and not too long a voyage to escape the miseries of an English winter and early spring, there is no place like Jamaica. For the sufferer from chronic rheumatism or gout or from incipient kidney trouble there is no better winter resort. For the idlers tired of the Riviera, Algiers, Madeira, or the Canary Islands there can be no better new sensation. While for the busy professional or business man who can give himself a month's holiday in glorious scenery and in the most delightful climate there can be no more attractive excursion. The directors of the Elder Dempster Line of Direct Imperial Mail Steamers have done great things in their endeavours to meet the reasonable wants of people going to this island. The two principal hotels have been bought, reorganised, and refurnished by them and they have made them, with a few trivial exceptions, not only comfortable but really sanitary. The steamers of the line are known to be some of the best found and most luxuriously fitted and worked of any ocean steamboats.

There are drawbacks, of course, to life in Jamaica and first among them I should place mosquitoes. But mosquitoes are not generally numerous, though they abound in certain districts. It is no doubt wise to sleep under mosquito nets; it is not considered to be necessary to take this precaution all the year but as it is now proved beyond doubt that mosquitos are the bearers of much, and much fatal, disease it is well to take every step to avoid their bites. The joint work of Principal Theobald and Dr. Grabham on "The Mosquitoes of Jamaica" is a monument of painstaking inquiry and the curious in such matters will do well to get it. Another insect plague of the island is ticks, said to have been introduced by some South American cattle. These little torments swarm everywhere and it is not safe to go off a beaten road on foot unless wearing high boots or leather gaiters. There is a curious story told about the upsetting of the balance of animal existence in connexion with rats, ticks, snakes (which are now extinct in Jamaica), and mongooses. There were once snakes in Jamaica, though I understand they were not very numerous. There were also rats which were extremely numerous. In order to keep the rats and snakes down the mongoose was imported from the East. This brave little beast soon completely cleared the island of snakes and it so harried the rats that in order to save themselves the rats took to the trees to live in and there they changed their diet and became egg-eaters and bird-destroyers. This state of things so reduced the number of birds that the cattle ticks increased and multiplied until they became the nuisance that they are, while now the ticks are said to be destroying the mongooses, getting inside their ears, whence the mongooses cannot evict them. Meantime the mongoose, deprived of its natural diet of snakes and rats, has taken to chickens, so that it in turn has become a ridiculous nuisance. I suspect this sequence of events may not bear strict investigation but it was repeatedly told to me as I have set it down.

The profuse and general hospitality of the island made our sojourn pass all too quickly. But at 4 o'clock on the tenth day of our stay we started to return with a very full complement of passengers. Of the incidents of the passage it is not necessary to say much. On the ninth day we made the coast of Ireland in the neighbourhood of Bantry Bay. The day was fine and clear and a more beautiful sight I never saw. The next day we arrived early in the morning at Avonmouth in the midst of a cold wet fog, a truly British welcome making us all long for the light and sun of the West Indies. The general impression made on me by the voyage was that the endeavour to make Jamaica a resort for tourists and certain classes of invalids ought to be a very great success and I believe it will. I have personally to thank Sir Alfred Jones and the Elder Dempster Company for a most thoroughly enjoyable and satisfactory holiday, all too short in duration.

Leamington.

FOUNDER'S DAY AT EPSOM COLLEGE.

FOUNDER'S Day was celebrated at Epsom College on July 29th, special interest being attached to the day's proceedings in consequence of its being the jubilee Founder's Day and owing to the opening of the Holman art and reading room which has been erected by subscription to commemorate the work done for the profession by Sir Constantine Holman, the treasurer of the College.

The proceedings commenced with a short service in the College chapel at 2.45 P.M., after which the visitors went to the big schoolroom to witness the distribution of prizes. Amongst those on the platform were Sir William H. Broadbent, Bart., who gave away the chief prizes; Sir William S. Church, Bart., chairman of the council; Sir Constantine Holman, Mr. J. Paul Bush, C.M.G., Dr. F. de Havilland Hall, Dr. John H. Galton, Mr. John H. Morgan, Dr. Frederick Needham, Mr. H. W. Kiallmark, and Dr. Guthrie Rankin.

The HEAD MASTER reviewed the scholastic work of the past year and referred to the various educational successes. He reported that all the teaching arrangements had been recently reviewed by inspectors under the Joint Universities Board, the result of which was generally satisfactory. As a consequence the Army Council had granted to the College the privilege of sending in candidates for leaving certificates admitting to the army competitive examination. A large number of boys were about to go into camp at Aldershot, and Epsom College was doing its best to carry out Lord Roberts's suggestion in regard to compulsory rifle training in schools. In conclusion he thanked the numerous distinguished visitors for coming amongst them and in referring to the treasurer, Sir Constantine Holman, he observed that he had worked entirely for others and no one could have higher praise than that.

At the conclusion of the distribution of prizes Sir WILLIAM BROADBENT gave an excellent address to the boys, reminding them that there were long distance runners as well as sprinters, and that pluck and perseverance were as essential as speed. Those boys who had taken prizes had also taken responsibilities, for they had given hostages for maintaining the high standard which they had already attained. After speaking of the importance of the public school spirit and of its value in after life, he concluded by reminding the boys that success and happiness were not convertible terms.

Sir WILLIAM CHURCH moved a hearty vote of thanks to Sir William Broadbent for his kindness in attending that day, and drew attention to the great interest which he had taken for many years in the work of the British Medical Benevolent Fund.

The proposition was seconded by Dr. NEEDHAM and carried with acclamation.

The visitors then proceeded to the Holman art and reading room, and as the gathering was far too large to be accommodated inside the addresses were made from the steps of the building.

Dr. GALTON, who initiated the Holman testimonial fund, in asking Sir William Broadbent to declare the building open, referred to the great services which Sir Constantine Holman had for so many years rendered to the various benevolent agencies of the profession, more especially to the Surrey Medical Benevolent Society and to Epsom College. It was mainly through his efforts that the title of the institution had been altered, and one proof of his hard work existed in the fact that he had collected a sum of £7000 for the benevolent work of the College. He stated that the room had been erected primarily for the boys' recreation but the teaching of art would be allowed in it.

The room was then declared open by Sir WILLIAM BROADBENT who referred to the numerous honours which had recently been conferred upon Sir Constantine Holman. In reference to the change in the name of the College he was glad to be able to say that the funds of the benevolent side of the institution had not suffered from the loss of contributions.

The visitors then proceeded to inspect the room, the swimming bath, and the other College buildings, after which they adjourned to the grounds where refreshments were served whilst a band played. A special attraction provided was a gymnastic display in the grounds under the direction of Sergeant Tancred, which was excellently performed and was greatly appreciated by the parents and friends of the boys. It is interesting to note that there are not more than two boys in each house who are unable to swim two lengths of the recently enlarged swimming bath.

THE BROMPTON HOSPITAL SANATORIUM AND CONVALESCENT HOME AT HEATHERSIDE, CAMBERLEY.

IN THE LANCET of June 25th, 1904, we published a brief account of this institution shortly before it was formally opened by H.R.H. the Prince of Wales. We have recently paid a second visit to the sanatorium in order to see it in working order. About 50 patients are now under treatment and it is intended to open the remaining beds as soon as possible.

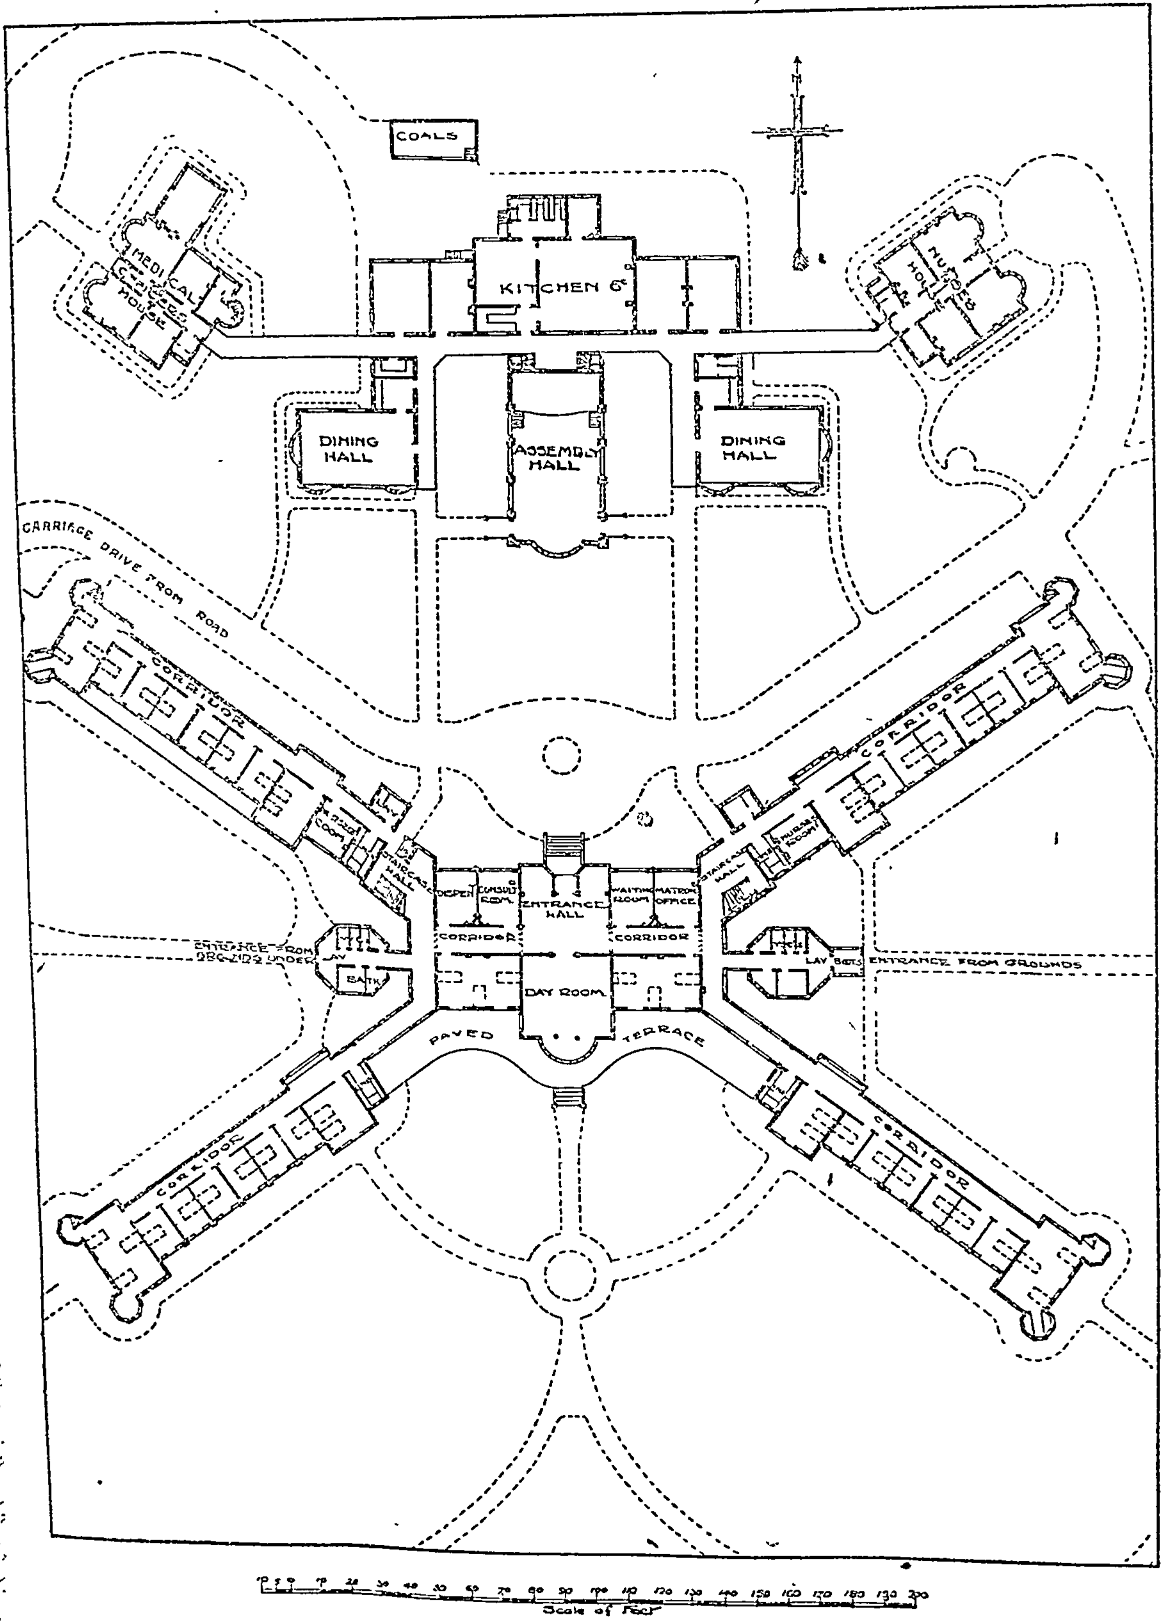
In erecting the buildings the committee of the Brompton Hospital had three objects in view. First, to submit early cases of pulmonary tuberculosis to open-air treatment in a dry and bracing climate for several months with a view to obtain arrest of the lung disease. Secondly, to educate a large number of patients in the system of hygienic or open-air treatment, so that having learnt these principles they may return to their own homes and become centres of instruction to others. Thirdly, to provide a convalescent home for other patients who have been treated in the parent institution. A few weeks in the fine air of Heatherside under medical supervision will, it is hoped, restore such patients sufficiently to enable them to resume suitable employment. After a careful examination of the buildings and appliances and after personal inquiries and observation we feel sure that the sanatorium and the system of treatment which is adopted will in every way amply carry out the above intentions.

The buildings stand on the Chobham Ridges, Surrey, 400 feet above sea level, about 30 miles from London, two miles from Frimley station, and three miles from Camberley. The surrounding region was known of old as Bagshot Heath and the Chobham Ridges border the large tract of uninclosed moorland belonging to the public, over which the War Office has acquired certain rights for military purposes.

The sanatorium grounds face for the most part south and command a fine view over Frimley Common, Farnborough, and Aldershot. A distant horizon is thus obtained. This is a matter of some importance. A limited horizon is likely to have a depressing effect on patients confined to bed or to their rooms from any cause, whilst a fine view of distant country produces an opposite effect. Except on the south the grounds are surrounded by the pine woods of the Heatherside estate. In the 20 acres belonging to the institution are to be found specimens of numerous varieties of pine, in addition to the pinus sylvestris. Numerous seats have been placed amongst the trees for the benefit of the patients who thus pass a large portion of their time in an atmosphere impregnated with the aroma of the pines. These woods afford an excellent shelter to the sanatorium from north and east winds and give needful shade in summer. The soil is gravel and sand and belongs to the Upper Bagshot series. The meteorological observations taken in the district show a dry sunny climate of a bracing character. The mean rainfall is 23 inches, the number of rainy days 183, the relative humidity 82·8 per cent., and the amount of cloud 7·4 per cent. The mean annual temperature is 48·6° F., the mean maximum 57·1°, and the minimum 40·5°, with a range of 16·2°. The buildings were designed by Mr. Edwin T. Hall, vice-president of the Royal Institute of British Architects, who has adopted an entirely novel and original design. As will be seen by the plan it consists of detached blocks and provides accommodation for 100 patients. (Fig. 1.) The main building has a central block and four radial pavilions. In the centre are the day rooms, facing south, yielding most pleasant shelter when their use is permitted by the medical superintendent. Access to these rooms is carefully regulated so that patients may only enter them at certain prescribed hours. In this portion of the building, also, are the consulting room, dispensary, matron's rooms and board room. There are also in this block four wards (two on each floor) containing three beds each. These are intended for patients who require special observation. Each of the radial pavilions is two-storeyed and contains accommodation for 22 patients in 12 wards holding one bed each, two wards containing two beds, and two containing three beds. Each floor is entirely disconnected from the other. All the rooms intended for the patients face S., SSE., or SSW., and behind are corridors, the windows of which are arranged opposite the doors of the wards, so that a perfectly free and ample current of air is provided for each room. The wings are placed at such angles that the front ones do not interfere in any way with the back ones and the latter receive as much sunshine and fresh air as the former. It will be observed on the plan that if a line be drawn at right angles from the patients' bedroom nearest the angle in the back wing it will (if extended) pass clear of the front wing, so that patients lying in bed in that room will have a full view of the country beyond. The object in adopting the radial form was to obtain the minimum distance between the centre of the building and the wards in the extremity of each wing. This is of obvious advantage in facilitating the nursing and feeding of those patients who may be confined to bed for a longer or shorter time. This form was an original idea on the part of the architect and has proved quite satisfactory. The size of a single bed ward is 12 × 11 × 10 feet or a cube of over 1300 feet. Considering the free entrance and egress of air this size is ample. There is no advantage in having these small wards higher than ten feet; a greater height would merely add to the cost of building without compensating advantages. The windows are made to reach to the ceilings and terminate by fanlights which are made to open at an angle of 90°. The doors to the rooms are provided with similar fanlights. All the wards in the pavilions are shallow so that the direct rays of the sun can reach the backs of the rooms. This cannot happen when the wards are made deep so as to contain many beds. The glass of the windows is carried down to within a foot of the floor. The lower storey is so arranged that patients in bed can be wheeled out on to the terrace, so as to be under the full influence of the sunshine and fresh air. As a matter of fact, nearly all the patients prefer to have their beds on the terrace at night also so as to sleep in the open air, and are only driven in by the stress of weather. Open balconies are formed at the end of each pavilion. The lower wards are provided with sun-blinds. Between each pair of pavilions is a detached sanitary tower containing the bath-rooms, lavatories, closets, sink-room, &c. To afford additional safety in case of fire, in addition to the main staircases there is a fire-escape staircase at the end of each pavilion, and further two of the pavilions are cut off from the rest of the block by a corridor built of fire-resisting material with a glass roof.

To the north, and quite detached from the main building, is a large hall which is intended as a recreation room. It is admirably lighted and ventilated. A dining room for the patients is situated on each side of the hall, communicating with the kitchens by covered ways. The kitchens, and accessory departments are arranged in a manner which considerably aids in the working of the department. At the east and west extremities of this portion of the buildings are respectively the residences for the medical officers and the nurses' home. At some distance from the sanatorium and near the main road is the machinery block, containing the boiler and engine houses, the laundry, the

FIG. 1.



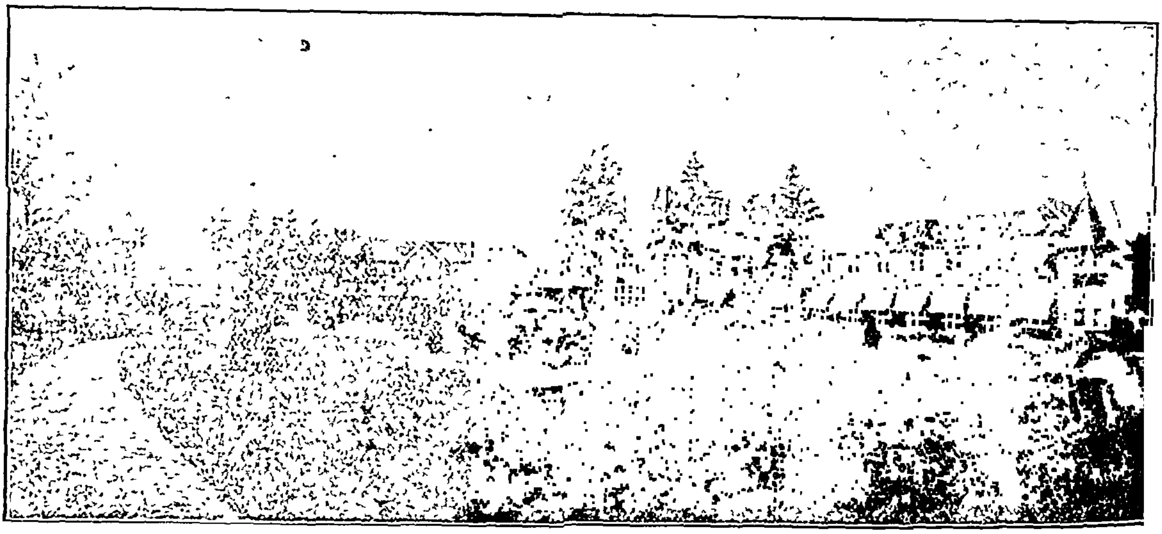
Ground Plan of the Camberley Sanatorium.

electric plant, the mortuary, and the laboratory. The institution is lighted by electricity, generated on the premises, all the plant being in duplicate. The buildings are heated by hot-water radiators. These are found to be preferable to steam radiators inasmuch as the temperature can be more easily regulated. An excellent device has been adopted to preserve the cleanliness of the walls above the radiators by placing above the radiators a sheet of metal which effectually prevents currents of heated air rising along the walls and carrying particles of dust with them. The radiators can be easily cleaned. The water is obtained from the Frimley waterworks which are at a short distance from the institution, and the drainage is connected with the Frimley main drainage scheme. A successful endeavour has been made in the external design ot the sanatorium to obviate the character usually associated with a hospital and to secure the appearance of a large country home or seaside pavilion. The mental effect thus produced on the patients of brightness and homeliness assists the general treatment. A building erected on the austere lines of barracks or an old-fashioned workhouse has a depressing effect which ought to be avoided. (Fig. 2.)

Passing now from a description of the buildings, a few words may be said as to the general lines of treatment adopted. In order that the educational value of such an institution as this may be fully utilised great stress is rightly laid on a daily routine rigidly adhered to. To keep a number of male patients idle for the several months required for the arrest of the disease and the commencement of reparative processes has a most demoralising effect. Enforced relaxation from all work during this period unfits them for resuming employment when they return home. A most praiseworthy scheme has been mapped out by the medical superintendent which may well serve as an example for similar establishments. Each patient is required to do some amount of light work daily. The daily routine is as follows. The patients rise at seven and take a cold bath. An ingenious system has been established by which scrambling for the use of the bath-rooms is entirely avoided and perfect order is maintained. Breakfast is at 8.15; work out-of-doors from 10 to 10.45; then a quarter of an hour for lunch; the patients work again till 11.55. Then there is an interval of absolute rest, the patients lying on their beds till 12.45. Dinner is at this hour, after which comes another period of rest. More work follows from 2.50 to 4.15. After tea the patients can go into the rooms where tables are provided so that they can write letters or play games. Supper is at 7.15; subsequently the reading rooms and concert room are available and all lights must be out at 9 P.M. The lowest grade of exercise is walking round a "measured mile" at a slow pace. If the temperature is not raised by such a procedure then light work, such as carrying baskets containing gravel, mould, &c., is enforced and subsequently work requiring more exertion is allowed, such as making paths and certain operations connected with gardening. Smoking is allowed for a quarter of an hour after each meal but only on the main road inside the grounds; elsewhere it is strictly forbidden. The meals are carefully supervised but there is no system of forced feeding.

The committee of the Brompton Hospital may be congratulated on having obtained a most valuable addition to its charity. In the future no hospital for the treatment of pulmonary tuberculosis should be built in a town; country air is an essential part of successful treatment. It is also acknowledged that the neighbourhood of the sea is by no means requisite but a site the nature of which we have alread suggested should be chosen. We trust that funds will b forthcoming which will free the minds of those responsibl for the working of the institution from any anxiety, both a regards the upkeep of the sanatorium and of the paren hospital at Brompton.

FIG. 2.



General view of the building.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary Comitia was held on July 27th, Sir RICHARD DOUGLAS POWELL, Bart, K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted as Members of the College: John Brian Christopherson, M.A., M.D. Cantab.; Lewis Augustus Clutterbuck, M.B. Durh.; Arthur Frederick Hertz, M.A., M.B. Oxon.; Conrad Meredyth Hinds Howell, M.A., M.B. Oxon., L.R.C.P. Lond.; Henry Percival Johnson, B.A. Cantab., L.R.C.P. Lond.; *Harold Campbell Parsons*, M.A., M.D. Toronto, L.R.C.P. Lond.; and William Morton Robson, M.D. Lond., L.R.C.P. Lond.

Licences were granted to 111 gentlemen who had passed the required examinations and conformed to the by-laws and regulations.

Diplomas in Public Health were granted to the following gentlemen: Jackson Arthur Atkinson, L.R.C.P. Lond., M.R.C.S. Eng.; Robert James Blackham (Captain, R.A.M.C.), L.R.C.P. & S. Edin., L.F.P. & S. Glasg.; Niel Campbell, M.B., C.M. Glasg.; Herbert Ernest Corbin, L.R.C.P. Lond., M.R.C.S. Eng.; Louis Courtauld, B.C. Cantab., L.S.A.; John William Fox, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng.; James Alison Glover, M.D., B.S. Cantab.; Walter Lisle Taylor Goodridge, L.R.C.P. Lond., M.R.C.S. Eng.; Hermann Lauder Hamilton, M.B., B.S. Aberd.; Edwin Charles Hayes (Captain, R.A.M.C.), L.R.C.P. & S. Edin., L.F.P. & S. Glasg.;

Henry Holt, M.B., B.S. Vict.; Percy Samuel Lelean (Captain R.A.M.C.), F.R.C.S. Eng., L.R.C.P. Lond.; Norman Forbes MacLeod, M.B., B.S. Glasg.; James Meek (Major, R.A.M.C.), M.D., M.S., R.U.I.; John William Myler, F.R.C.S. Eng., L.R.C.P. Lond., M.D. Brux.; John Nightingale, M.D., M.S. Edin.; James Farquharson Powell, L.R.C.P. Lond., M.R.C.S. Eng.; John Elliott Robinson, L.R.C.P. Lond., M.R.C.S. Eng.; and Eugene Dunbar Townroe, L.R.C.P. Lond., M.R.C.S. Eng.

The PRESIDENT announced that the report of the plague committee had been presented to the Secretary of State for India and that the plague committee had been invited to wait upon him, when he expressed his gratitude to the Royal College of Physicians of London and announced his intention of forwarding the recommendations of the plague committee to India.

The PRESIDENT nominated Dr. G. R. Murray to deliver the Bradshaw lecture on Nov. 7th, the subject being Exophthalmic Goitre and its Treatment; and Dr. Norman Moore to deliver the two Fitzpatrick lectures on Nov. 9th and 14th —Lecture I. On John Mirfield (1393) and Medical Study in London during the Middle Ages; and Lecture II. On Dr. Edgar Browne (1644–1708) and the Education of Physicians in London in the Seventeenth Century.

The following communications were received:—

1. From the Clerk of the Privy Council (July 7th) inclosing a programme of an International Congress on Physio-Therapeutics to be held at Liége on August 12th next, and stating that if the College appointed a representative the Lord President would recommend him for credentials as a British delegate. The PRESIDENT nominated Dr. H. Lewis Jones as the representative of the College.

2. From the secretary of the Royal College of Surgeons of England reporting certain proceedings of its Council on July 13th.

3. From the chaplain of Bethlem Hospital asking leave to photograph the portraits in possession of the College of the Doctors Monro who were successively physicians to the hospital.

4. From Messrs. Hutchinson and Co., publishers, asking leave to reproduce, in a life of Queen Henrietta Maria by Miss Ida A. Taylor, the portrait of Sir Theodore Mayerne in possession of the College. In both cases leave was granted, subject to the reservation that the reproduction should be used for the purpose asked only.

On the nomination of the PRESIDENT and Council the following appointments were made:—Censors: Dr. Joseph Frank Payne, Dr. Norman Moore, Dr. Frederick Taylor, and Sir Thomas Barlow. Treasurer: Sir Dyce Duckworth. Emeritus registrar: Sir Henry Alfred Pitman. Registrar: Dr. Edward Liveing. Harveian librarian: Dr. Payne. Assistant registrar: Dr. Oswald Auchinleck Browne. Elected members of the Library Committee: Dr. Philip Frank, Dr. Norman Moore, Dr. Archibald Edward Garrod, and Dr. Humphry Davy Rolleston. Curators of the museum: Dr. Henry Charlton Bastian, Dr. William Cayley, Dr. Seymour John Sharkey, and Dr. John Abercrombie. Finance committee: Dr. F. de Havilland Hall, Dr. David Bridge Lees, and Sir Edwin Cooper Perry. Examiners: chemistry and chemical physics—Mr. John Millar Thomson, F.R.S., Mr. Frederick Thomas Trouton, F.R.S., Mr. Frederick Daniel Chattaway, Ph.D., D.Sc., and Mr. John Addyman Gardner, F.C.S., F.I.C.; materia medica and pharmacy—Dr. Cyril Ogle, Dr. John Henry Bryant, Dr. Joseph John Perkins, Dr. Francis Whittaker Tunnicliffe, and Dr. James Purves Stewart; physiology—Dr. Ernest Henry Starling, Dr. Bertram Louis Abrahams, and Dr. Leonard, Erskine Hill; anatomy—Dr. Peter Thompson and Dr. Robert Howden; medical anatomy and principles and practice of medicine—Dr. F. de Havilland Hall, Dr. Samuel Hatch West, Dr. Theodore Dyke Acland, Dr. George Newton Pitt, Dr. William Collier, Dr. Hubert Montague Murray, Dr. Norman Dalton, Dr. Frederick John Smith, Dr. Walter Essex Wynter, and Dr. John Rose Bradford; midwifery and diseases peculiar to women—Dr. Francis Henry Champneys, Dr. John Phillips, Dr. Edward Malins, Dr. William John Gow, and Dr. Thomas Watts Eden; public health—(Part I.) Dr. Arthur Pearson Luff and (Part II.) Dr. William Heaton Hamer.

Captain Leonard Rogers, I.M.S., elected a Fellow on April 27th last, being resident in Calcutta, was admitted *in absentia* and the seal of the College was set to his diploma.

Reports were received from Dr. C. Theodore Williams on a visit which he paid as representative of the College to the new buildings of the University of Birmingham, and from Dr. Frederick T. Roberts on his attendance as representative of the College at a Court of Governors of the University of Sheffield. In both cases they were thanked on the motion of the PRESIDENT.

Two reports, dated June 19th and July 10th, were received from the Committee of Management, recommending: (1) that the South African College, Cape Town, be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and biology; (2) that the University of Leeds be added to the list of universities whose examinations are accepted under the conditions of Paragraph II. Section III. of the Regulations in lieu of the First and Second Examinations of this Board; and (3) that Uppingham School, which has been visited by a member of the committee and reported as fulfilling the requirements of the Board, be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and biology. These reports were adopted.

The quarterly report of the College finance committee, the annual report of the library committee, the annual report of curators of the museum, and the report of the examiners for the licence on the results of the April examinations were received and adopted.

Books and other publications presented to the library were received and the thanks of the College were returned to the donors. Among them may be mentioned a first edition of Celsus' "De Medicinæ," given by Professor W. Osler, and some interesting books and papers from Miss Greenhill and Dr. W. H. Allchin.

The newly elected officers, examiners, and members of standing committees gave their faith to the College.

The PRESIDENT then dissolved the Comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the council was held on July 27th, Mr. JOHN TWEEDY, the President, being in the chair.

It was resolved that diplomas of Membership should be issued to 103 successful candidates and that, jointly with the Royal College of Physicians of London, diplomas in public health should be issued to 19 successful candidates.

On the recommendation of the museum committee it was decided to purchase two additional tables for the display of anatomical specimens in the museum.

A report from the finance committee was received and approved. The chief points in the report are as follows:—The gross income of the College amounted to £25,755, being £1214 less than in the previous collegiate year; the expenditure of the College amounted to £23,025 or £1149 less than the expenditure of the previous year, therefore the balance of income over expenditure amounts to £2730 and is only £64 less than the balance last year.

Mr. Henry Morris was re-elected a member of the executive committee of the Imperial Cancer Research Fund.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8609 births and 4490 deaths were registered during the week ending July 29th. The annual rate of mortality in these towns, which had been 11·6, 12·9, and 13·4 per 1000 in the three preceding weeks, further rose last week to 15·0 per 1000. In London the death-rate was 14·3 per 1000, while it averaged 15·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·1 in Burton-on-Trent, 4·2 in Willesden, 4·5 in King's Norton, 5·9 in Ipswich and in Handsworth (Staffs), 6·2 in Hastings, 6·3 in Walthamstow, 6·4 in Croydon, and 6·7 in Tottenham; the highest rates were 20·0 in Salford, 21·7 in Stockport, 22·1 in Manchester, 22·3 in Rochdale, 22·6 in Hanley and in Sheffield, 23·7 in Liverpool, 24·0 in Merthyr Tydfil, 24·6 in Rhondda, and 30·7 in Bootle. The 4490 deaths in these towns last week included 1101 which were referred to the principal infectious diseases, against 388, 486, and 612 in the three preceding weeks; of these 1101 deaths, 861 resulted from diarrhœa, 82 from whooping-cough, 77 from measles, 33 from diphtheria, 26 from scarlet fever, 21 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Bournemouth, Ipswich, Burton-on-Trent, King's Norton, or Tynemouth; while the highest death-rates from the principal infectious diseases were recorded in West Ham, Aston Manor, Stockport, Liverpool, Bootle, Barrow-in-Furness, Sheffield, Rhondda, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Wolverhampton, Barrow-in-Furness, and Sunderland; from scarlet fever in Bootle; from diphtheria in Barrow-in-Furness; from "fever" in Devonport; and from diarrhœa in West Ham, Aston Manor, Stockport, Birkenhead, Liverpool, Bootle, Sheffield, Rhondda, and Merthyr Tydfil. The mortality from whooping-cough showed no marked excess in any of the large towns. One fatal case of small-pox was registered in Derby but none in any other of the 76 towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been five, four, and three at the end of the three preceding weeks, was again three at the end of last week; no new cases were admitted during the week, against two, two, and none in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, July 29th, was 2550, against 2499, 2520, and 2485 on the three preceding Saturdays; 352 new cases were admitted during the week, against 354, 356, and 304 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 90, 104, and 117 in the three preceding weeks, declined to 116 last week, and were two below the number in the corresponding period of last year. The causes of 48, or 1·1 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Newcastle-on-Tyne, and in 45 other smaller towns; while the largest proportions of uncertified deaths were registered in Birmingham, Rochdale, Burnley, Preston, Bradford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·7, 14·3, and 15·2 per 1000 in the three preceding weeks, further rose to 15·3 per 1000 during the week ending July 29th, and was 0·3 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·9 in Leith and 11·2 in Aberdeen to 19·1 in Dundee and 21·3 in Perth. The 513 deaths in these towns last week included 39 which were referred to diarrhœa, 14 to whooping-cough, eight to measles, and five to diphtheria, but not any to small-pox, to scarlet fever, or to "fever." In all 66 deaths resulted from these principal infectious diseases last week, against 57, 55, and 61 in the three preceding weeks. These 66 deaths were equal to an annual rate of 2·0 per 1000, which was 1·7 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 13, seven, and 22 in the three preceding weeks, further rose last week to 39, of which 20 occurred in Glasgow, six in Edinburgh, six in Dundee, and five in Paisley. The deaths from whooping-cough, which had been 26, 25, and 12 in the three preceding weeks, rose again to 14 last week, and included four in Glasgow and two each in Edinburgh, Dundee, Aberdeen, Greenock, and Perth. The fatal cases of measles, which had been 14, 19, and 21 in the three preceding weeks, declined again last week to eight, of which five were registered in Glasgow and three in Perth. The deaths from diphtheria, which had been three, one, and three in the three preceding weeks, further rose to five last week and included four in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 65, 65, and 62 in the three preceding weeks, rose again last week to 70, and were 15 in excess of the number in the corresponding period of last year. The causes of 13, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 16·9, 19·7, and 20·1 per 1000 in the three preceding weeks, further rose to 20·8 per 1000 during the week ending July 29th. During the past four weeks the death-rate has averaged 19·4 per 1000, the rates during the same period being 12·5 in London and 16·1 in Edinburgh. The 151 deaths of persons belonging to Dublin registered during the week under notice were five in excess of the number in the preceding week and included 22 which were referred to the principal infectious diseases, against eight, 17, and 20 in the three preceding weeks; of these, 20 resulted from diarrhœa, one from measles, and one from "fever," but not any from small-pox, from scarlet fever, from diphtheria, or from whooping-cough. These 22 deaths were equal to an annual rate of 3·0 per 1000, the mean rates last week from the principal infectious diseases being 2·9 in London and 1·9 in Edinburgh. The fatal cases of diarrhœa, which had been six, 14, and 18 in the three preceding weeks, further rose last week to 20. The 151 deaths in Dublin last week included 51 of children under one year of age and 29 of persons aged 60 years and upwards; the deaths of infants exceeded the number in the preceding week, while those of elderly persons showed a slight decline. Six inquest cases and four deaths from violence were registered; and 51, or more than a third, of the deaths occurred in public institutions. The causes of six, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: A. F. Harper to the *Dominion*, on commissioning; C. J. Mansfield to the *Racer*, for Osborne College; H. F. Iliewicz to R.N. Engineer College, Devonport; R. E. Biddulph to the *Cressy*; and F. J. Burns to the *Bacchante*, on recommissioning. Staff Surgeons: S. Conner to the *Cormorant* for Gibraltar Hospital; R. Hill to the *Renown*: P. H. M. Star to the *Roxburgh*, on commissioning; and T. W. Philip to the *Nelson*, on the *Roxburgh* commissioning. Surgeons: A. F. Fleming to the *Dominion*, on completing; A. B. Marsh to the *Hindustan*, on completing; F. F. Mahon to the *Excellent*; C. Shepherd to the *Pioneer*; and R. Waterfield to the *Colossus*, on the *Roxburgh* commissioning.

ROYAL ARMY MEDICAL CORPS.

Lieutenant H. W. Long to be Captain (dated May 19th, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel W. L. Stewart having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated August 2nd, 1905). Surgeon-Captain W. A. Griffiths having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated August 2nd, 1905). Surgeon-Captain H. P. Job having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated July 29th, 1905). Surgeon-Major W. J. Harnett having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated July 29th, 1905).

VOLUNTEER OFFICERS' DECORATION.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force, who have been duly recommended for the same under the terms of the Royal Warrant (dated July 25th, 1892):—*Eastern Command*: *Rifle*: 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Lieutenant-Colonel Henry William Roberts. *Medical Corps*: East Surrey Bearer Company, Royal Army Medical Corps (Volunteers): Major John James de Zouche Marshall. *Scottish Command*: *Rifle*: 1st Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Lieutenant-Colonel William Sneddon. 1st (Ross Highland) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Lieutenant-Colonel John Adam. *Volunteer Rifle Corps*: 5th (Glasgow Highland) Volunteer Battalion, the Highland Light Infantry: Surgeon-Major Angus Macphee. *Northern Command*: *Artillery*: 1st Lancashire Royal Garrison Artillery (Volunteers): Surgeon-Major Thomas Moore Dawson. *Rifle*: 2nd Volunteer Battalion the East Lancashire

Regiment: Surgeon-Lieutenant-Colonel Andrew Alexander Watson.

EXAMINATION FOR COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS.

The undermentioned gentlemen, 17 of whom possess university degrees, were successful at the recent examination in London for commissions in the Royal Army Medical Corps for which 60 candidates entered:—

Names.	Marks.	Names.	Marks.
John Allan Anderson ...	582	Percy Farrant	479
Cuthbert Garrard Browne	577	Albert Edward Francis Hastings	479
Hugh Godwin Sherren ...	568	George William Webb Ware...	474
Henry Horace Andrews Emerson	560	Michael Balfour Hutchison Ritchie ...	473
Wallace Benson	549	James Stuart Dunne ...	470
Rowland Philip Lewis ...	548	William McConaghy ...	466
George Edward Ferguson	543	Francis Cornelius Sampson	461
James Herries Graham ...	538	Charles Francis White ...	461
Charles Ernest White Spinner Fawcett	529	Cecil John Wyatt	453
Thomas Scatchard	519	Wilfrid Cowan Nimmo ...	450
Ronald Anderson Bryden	502	Edmund Thurlow Potts	448
Arthur Edmund Stewart Irvine	499		445
Thomas Bettesworth Moriarty	499		445
Alexander Macgregor Rose	499		441
Edward Lawton Moss ...	497	Arthur James Arch ...	439

INDIAN MEDICAL SERVICE EXAMINATION.

The following gentlemen, eight of whom possess university degrees, were successful at the examination for admission to the Indian Medical Service held on July 25th and four following days:—

Names.	Marks.	Names.	Marks.
C. E. Palmer	3407	W. D. Wright	3164
C. H. Reinhold	3395	V. N. Whitamore	3158
A. F. Hayden	3348	J. F. Boyd...	3150
B. E. M. Newland	3303	N. S. Sodhi	3081
E. J. C. McDonald... ...	3278	J. Catto	3054
L. A. H. Lack	3273	W. C. Gray	3041
K. W. Mackenzie	3187	W. J. Powell	3034

Forty-two candidates (27 of whom had university degrees) competed for the 14 vacancies.

THE WAR IN THE FAR EAST.

The *Russkoe Slovo* states that the late commander-in-chief of the Manchurian army, General Kuropatkin, having proposed that the members of the staff of the provincial detachments should be decorated, the members of the medical profession and the field surgeons opposed the idea. Since then the new commander-in-chief, General Linievitch, raised the proposal again expressing his wish that medical men, field surgeons, and sisters of mercy belonging to the provincial sanitary detachments working south of Gundzhulin should be rewarded. His proposal has met with the same reception as that of his predecessor, for the major portion of the provincial sanitary and medical men insist that the only reward for what they may do must be consciousness of duty done.

Surgeon-General Sir Benjamin Franklin, K.C.I.E., I.M.S., has been appointed a Knight of Grace of the Order of St. John of Jerusalem in England.

Correspondence.

"Audi alteram partem."

THE CAUSE OF SENILE DECAY.

To the Editors of THE LANCET.

SIRS,—Under a perfect system one would expect man right to the end of his mortal career to grow in strength and wisdom, passing from higher plane to higher plane. But it has been ordained that, having reached his zenith, he shall slowly retrograde and with ever-waning powers totter to the grave. What, I would ask, are the pathological—or, as I would prefer to say, "physiological"—causes of this senility? Does the organism wear out like any other piece of machinery? Or are we to suppose that with advancing years its energies become spent, as in a piece of clockwork slowly running down? Or, again, can we explain the phenomena of senility simply as being part of a vital cycle, the cellular elements of the tissues tending, through inherent proclivities impressed upon them by heredity, to pass through a definite cycle of which senile decay is the final phase?

A little consideration will show that we cannot in any of these ways fully explain the occurrence of senile decay. If this were simply a process of wearing out it should surely start with the beginning of active life, whereas, as a matter of fact, it is precisely during the active early years of life, when on this view wear and tear should be greatest, that the tissues, far from wearing out, actually improve in structure. It is, moreover, impossible thus to explain the varying ages at which senility makes its appearance in different species. A dog, e.g., becomes senile at an age when the human is not yet half mature and it is barely conceivable that the cells of this animal should have an inherent tendency to wear out long before those of man have reached maturity. No, the animal organism does not wear out like a tin pot or a pair of boots. The view that senility is due to an exhaustion of vital energy may be at once dismissed, founded as it is on an altogether false analogy, for in the matter of energy there is no real analogy between a living organism and an inanimate machine. Finally, the assumption that the tissues become senile owing to an inherent tendency determined by heredity does not explain those remarkable cases of premature senility in which the hair turns grey, the skin wrinkles, and the arteries become brittle before the normal age of puberty has been reached. It cannot seriously be contended that such cases are due to an innate tendency for the individual cells of the body to become prematurely senile: there must be some coördinating mechanism at work.

We cannot, I repeat, fully explain the phenomena of senility in any of the ways suggested. A much more probable explanation is that the organism in large measure brings about its own senility—that, in fact, it deliberately and of set purpose commits slow suicide with the object of limiting its existence, the limit thus imposed being definite for each species and one most conducive to the welfare of the species, and that the self-destroying instrument strikes chiefly through the blood plasma. In considering the causation of senile decay we must think of the organism as made up of a number of cells—nerve cells, muscle cells, gland cells, and the rest. Now it is evident that the senility of the organism as a whole is due to the senility of its constituent cells, and the contention is that these latter become senile not so much from causes resident in themselves as because with advancing years the plasma environing them alters in composition, and by virtue of this altered composition—as well as alterations in respect of the plasmic circulation—sets on foot that gradual dissolution of cell organisation which characterises old age.

If the various cells of the body were at shortly recurring intervals replaced by new descendants it is clear that the tissues would retain their youth throughout life but, as a matter of fact, the more highly organised cells, such as those of nerve, muscle, and (most) glands, cannot give birth to new cells; those originally laid down in embryo last for the lifetime of the individual and thus have ample time for "growing old." Now, though doubtless there is an inherent tendency for all cells ultimately to become senile, it is probable that they have also a tendency to immortality. I cannot but think that the fate of the tissue cells, both in respect of development and decay, is less dependent upon unaided developmental proclivity and more upon environmental influences than we are wont to suppose. Certainly the growth and development of the individual are largely due to specific influences operating through the blood plasma, influences which come into operation in definite sequences and *compel* the tissues to grow and develop along certain lines. Thus, if the thyroid gland fails to yield its proper secretion cretinism results; if the blood is bereft of a substance yielded by the pancreas the individual does not pass beyond the infantile stage of existence; and, again, in the absence of ovaries and testes the developmental changes characteristic of puberty do not take place.

But if this is true of growth and development why should it not also be true of decay? In point of fact I believe it is, and that if the tissues were to continue throughout life to be flushed with healthy juvenile blood they would retain to extreme age much of their youthful nutritional vigour; and contrariwise, that if the tissues of the child were fed with senile blood (as actually happens, I would suggest, in cases of premature senility) they would forthwith tend to undergo senile degeneration. On this view a man grows old because his blood grows old, the organism being slowly destroyed by means of the blood plasma.

We do not yet know the nature of the changes which the blood undergoes with advancing years but we may be quite sure that they are of a definite kind and that the age of the individual is written as plainly in his blood as in his tissues. I believe it will be found that modifications in respect of internal secretions figure largely in these changes. We have seen that the internal secretions play an important part in determining growth and development and my own observations lead me to believe that normal senile degeneration is largely brought about in the same way. But the blood of the aged also undergoes other changes. It tends to get poor in quality, to be deficient in hæmoglobin and foodstuffs, and to contain an excess of excretory material, while from failure in the circulatory system its supply is apt to be defective. These are all additional factors in bringing about senile decay and as they are, to some extent, under our control we have it so far in our power to retard that decay. More than this we can scarcely hope to do until we possess a more intimate knowledge of the composition of senile blood, and it is doubtful whether even this knowledge would enable us to do much to lengthen man's days. The most effective way of doing this would be to allow only those belonging to long-lived families to propagate the race. In this way the span of life might be extended almost indefinitely.

Metchnikoff's contention that senility is in great measure due to the absorption of poisons from the large bowel is, in my belief, untenable. Were it true the individual ought to begin to get senile immediately after birth, whereas under normal conditions no senile changes occur during the years of developmental life, or, indeed, for some time afterwards. The fact is that senility does not begin until the senile-producing mechanisms come into play. The assumption that the human large bowel is wholly redundant gives nature the credit for being a bungler indeed. Can anyone seriously maintain that a child coming into the world with his ileum terminating at the anus would develop into a more vigorous being, enjoy better health, and live longer than if he had been endowed with the normal length of digestive tube?

I am, Sirs, yours faithfully,

Wimpole-street, July 23rd, 1905. HARRY CAMPBELL.

THE INCREASE OF CANCER AND THE USE OF ALCOHOL.

To the Editors of THE LANCET.

SIRS,—In a leading article in a recent issue of THE LANCET you refer to the discussion by the Life Assurance Medical Officers' Association of the problems of cancer mortality. May I ask space for some further comments on a subject of such engrossing interest? As regards the increase of cancer, real or apparent, it is doubtless scientifically right to treat this as still *sub judice*. The Imperial Cancer Research Fund will, I hope, soon announce its conclusions. In the meantime, to the plain man the evidence strongly points to the reality of the increase, and it will be wise to accept this as a fact for practical purposes. When the deaths from any disease in both sexes increase during a long course of years, so that the rates of mortality calculated upon them with all known precautions against fallacy and allowance for change in age distribution of the population show an increase, uniform, progressive, and considerable, the plain man will believe that the increase in the fatality of that disease is a real one. When a general tendency to increase is also reported from other registering countries, including our colonies, continuous in the case of most countries, "fluctuating but progressive" in Ireland, the Netherlands, and New Zealand,[1] this conclusion is strengthened. An augmentation in the course of 30 years of 147 per cent. for males and of 74 per cent. for females in the corrected mortality-rate of cancer[2] is not readily to be explained by improved diagnosis and certification. The last year for which returns have been published (1903) confirms the tale. There is a substantial increase in the corrected mortality from cancer upon the average of the five preceding years in both sexes and in both urban and rural counties. The rates for 1903 are the highest on record.[3] Surgical procedure has during the past 30 years greatly advanced, many more lives of cancer patients have been saved, and very many more have been lengthened. This should have diminished the mortality. The onus of proof lies, I think, heavy on those who would deny the reality of the increase. Until wholly new evidence has been produced we shall do well to accept Dr. J. F. Payne's masterly summing up of the question[4] and to act upon the conclusion that we have to deal in medical practice to-day with the momentous fact of an *actual* and *progressive* increase of cancer in the community at large.

Your article alludes to the relation of the use of alcohol to cancer. It was venturesome on my part to raise this question before the Life Assurance Medical Officers' Association because it is so easily misunderstood. Any primary causal relationship between the use of alcohol and cancer is out of the question. Teetotallers are by no means exempt from the disease. But the use or abuse of alcohol may nevertheless have a secondary influence. There are grounds for a suspicion that this is the case. Let me state a hypothesis. I shall be unable to prove its truth but I can state *primâ facie* evidence of its probability. "The extended use of alcohol during the past half century has promoted the occurrence of cancer of the digestive tract and has thus been one cause of the increased mortality from cancer."

A brief outline of the evidence is as follows: 1. "56 per cent. of the total mortality from cancer is due to carcinoma of the digestive organs."[5] The progressive increase in the cancer death-rate has been especially noticeable in cancer of these organs. Dr. Payne establishes this from the Reports of the Registrars-General for England and Wales (1868 to 1888) and for Ireland (1887 to 1897), and from statistics of St. Thomas's Hospital.[6] Dr. W. S. Lazarus-Barlow and Dr. Gordon Taylor found the same fact in those of the Middlesex and St. George's Hospital.[7] Personal clinical experience confirms this. Mr. Rutherford Morison, surgeon to the Royal Infirmary, Newcastle-upon-Tyne, writes in THE LANCET of June 17th: "So far as my own experience goes, the increase is largely in cases of cancer of the gastro-intestinal tract." 2. The consumption of alcohol has much increased during the last 50 years, coincident with the greater prosperity of the people. 3. Occupations associated with the free use of alcohol show a high liability to cancer. This is proved by the statistics of occupation mortality from cancer given by the Registrar-General (1881–1890) and quoted by Dr. Payne, in which he shows that commercial travellers, inn servants, innkeepers, and brewers die from cancer at rates from 30 to 50 per cent. above the average of occupied males. 4. There is reason to think that persons who abstain from alcohol have an average lower death-rate from cancer than those who take alcohol. Dr. A. Newsholme's statistics[8] on this head, to which you allude, comprise three years' cancer mortality amongst assured male lives in the United Kingdom Temperance and General Provident Institution. He found that the cancer death-rate of the abstainers from alcohol, calculated upon the lives at risk and adapted to a "standard million" of population, was 72 per cent. of the death-rate of non-abstainers. Two things have to be noted here. One is that the figures are small—47 deaths of abstainers and 78 of non-abstainers registered as due to malignant disease. Another fact is that the death-rate of abstainers from all causes in that institution follows the same course as the cancer death-rate, being less than that of non-abstainers in almost exactly the same proportion. The difference may, again, be caused by the presence of a few intemperate persons amongst those who take alcohol. 5. There is an impression derived from clinical experience that free alcohol-drinkers are especially liable to cancer of the digestive organs. It is difficult to submit evidence of this. Some figures which I placed before the Life Assurance Medical Officers' Association are of this nature but they are too small to be conclusive. They were taken from carefully verified life assurance records and formed part of mostly consecutive series of 2000 deaths from all causes. There were 114 males dying from malignant disease. I divided them into three groups: 41

[8] Brit. Med. Jour., 1903, vol. ii., p. 1529.

abstainers, 29 uncertain, and 44 users of alcohol. The disease was located in the alimentary tract in 34 per cent. of the abstainers, in 48 per cent. of the uncertain class, and in 64 per cent. of the drinkers. Thus in those who took alcohol (and a few of these would probably be intemperate) the digestive tract proved to be much more often the site of the disease than in those who abstained.

It will be conceded that the hypothesis that the extended use of alcohol has increased the number of cases of cancer of the alimentary tract would explain the facts that I have put forward. Nor is it difficult to believe that the continual application of alcohol to the digestive canal, producing as it does congestion of its lining membrane, would promote any existing tendency to that localised cell-proliferation which is an essential feature of malignant growth. No one, however, is more ready than myself to admit that this is only a hypothesis. Reasonable hypotheses, however, are valuable, since, as Sir William R. Gowers remarks, even when they prove erroneous their disproof always involves addition to our knowledge. I hope that fuller observations will be made by those who have the opportunity of doing so. Reverting to the phenomenon of cancer increase, if we glance back to the early part of last century we see three chronic diseases acting as scourges of civilised man—tubercle, cancer, and syphilis. Of tubercle we have learnt much since then both as to its nature and remedy. Cod-liver oil was introduced into Britain by Dr. Hughes Bennett in 1841, Koch discovered the bacillus in 1882, and the open-air treatment has been developed of recent years. We can now often cure and, what is better, prevent, and in consequence the tubercle death-rate has greatly fallen. The nature and course of syphilis have been demonstrated by a long line of illustrious men. The discovery and use of the alkaline iodides and the definition of the place of mercury in treatment, especially by Mr. J. Hutchinson's classical paper before the Hunterian Society in 1874, have disarmed the disease of much of its venom. The human wrecks, riddled with syphilis of skin and bone, which I saw so often when a student 30 years ago, are met with now but seldom. Far different is it with cancer, of the nature and cause of which we have little more knowledge—knowledge that is fruitful of practical outcome—than in the days of Baillie. Our remedy is still the knife alone, that last resort of art, extirpating what it is powerless either to prevent or to control. Thus two of these diseases have yielded much of their virulence to the advance of science. Can it be that cancer attacks some subjects of lesser resistance which now escape the other diseases? Or is there a struggle for existence amongst diseases and when two are partly worsted a third may prosper?

I am, Sirs, yours faithfully,

Weymouth-street, W., July 11th, 1905. R. HINGSTON FOX.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING AT LEICESTER.

To the Editors of THE LANCET.

SIRS,—In your very full report in THE LANCET of July 29th of my remarks made at the opening of the discussion on the Surgical Treatment of Non-malignant Diseases of the Stomach there is one mistake. On page 327, column 2, the first sentence reads:—

> In one case Mr. Moynihan recognised the existence of an hour-glass stomach but failed to see that the stomach was trifid and so the operation failed of its purpose.

The case of trifid stomach was recorded in THE LANCET of August 8th, 1903, p. 388, and was given in detail on p. 169 of the pamphlet which I distributed at the meeting. The report received with regard to this patient in June, 1905, was that she was "completely cured, had gained 2 stones in weight, and could eat anything."

I am, Sirs, yours faithfully,

Leeds, July 29th, 1905. B. G. A. MOYNIHAN.

To the Editors of THE LANCET.

SIRS,—I regret to notice that in your report of the proceedings in the State Medicine Section I am represented as having said that I felt the necessity for an inquiry concerning the value of hospital isolation in the case of other infectious diseases than small-pox. Will you allow me to correct this report and to say that I did not express and do not hold this opinion?

I am, Sirs, yours faithfully,

PHILIP BOOBBYER,
Nottingham, July 29th, 1905. President of State Medicine Section.

A NEW CHLOROFORM AND ETHER REGULATING INHALER.

To the Editors of THE LANCET.

SIRS,—I have read with interest Mr. Harvey Hilliard's account of his new chloroform and ether regulating inhaler in THE LANCET of July 29th, p. 296. Unfortunately, "comparisons are odious," and the comparisons he draws between the Vernon Harcourt inhaler and his own being distinctly unfavourable to the former perhaps room will be found in your columns for an expression of opinion by one who knows neither party and who has no interest in either invention. True, I cannot speak of Mr. Hilliard's invention, for I know nothing of it beyond what I have learned from his own lucid account in your pages. What, then, can I say? This: for nearly a quarter of a century I have been administering anæsthetics with greater or less frequency to all kinds and classes of patients under all sorts of conditions by means of all forms of inhalers, from the simple towel of Edinburgh to the more imposing and impressive machinery becoming one who earns his daily bread as an anæsthetist. I am not going to say when I passed my millennium but hitherto I have not had a death. This I mention to explain my increasing feeling of nervousness. It may be stupid but I felt that with every case my turn was drawing nearer. So strong did the feeling become that I began to avoid calls to give an anæsthetic. How relieved I was when I heard of Vernon Harcourt I cannot express here, especially as I had a very nervous patient whose friends objected to an operation because one of their circle had died under an anæsthetic and from a certain likeness between the two they were certain that it would be fatal in this case also. The operation was necessary. The patient would have no other anæsthetist. With the Vernon Harcourt inhaler I had not the least anxiety. The anæsthesia was light but perfect and the patient awoke saying, "Why don't you begin?"

In the case of a nervous lad to whom I had given chloroform with a Junker's inhaler (he took it very badly) I was asked to give it again for an operation (removing a tumour in the region of the parotid and submaxillary glands) which would be lengthy and require the utmost quietude. I began in the usual way with pure air until he got accustomed to breathing quietly, then by moving the index finger one mark every minute (by the watch) in seven minutes I had him completely under and for a whole hour by the watch he made not a single movement. Yet the anæsthesia was light. With it I have given chloroform to twins a few months old for phimosis. In fact, I have used the Vernon Harcourt inhaler in a fairly representative set of cases with the utmost comfort and safety to my patients and pleasure to myself. Nor can I say more than if I needed an anæsthetic for myself—a thing I confess I have always dreaded—I should feel no anxiety if the Vernon Harcourt inhaler were used.

I have dwelt on these preliminary points to show that I am not ignorant of what I am writing about. 1. That the apparatus is cumbersome. I have not found it so. Sometimes I have it hung on the wall and the vapour conveyed to the mask by a tube. 2. That it is inconvenient. Not if one learns to hold it aright. I have used it in the most awkward positions and cannot assent to this statement. 3. That the air-ways are restricted by right-angled bends. Theoretically that sounds feasible but practically I have not found it so. It was marvellous how the valves responded to the respiratory movements of a tiny and fragile infant. And what a help it is to hear or to see these valves. I remember at a discussion on chloroform at the Royal Medical and Chirurgical Society how emphatically the great authorities in those days laid it down as a principle that one must watch the respirations keenly. It struck me the more forcibly because Sir Lauder Brunton almost commanded us to have our "Junkers" fitted up with a feather indicator. And although the mask I used in the case of the twins was far too big for their tiny faces, yet "click-click" went the valves and with that sound in my ears I was happy. 4. That it is incapable of giving a sufficient dose of chloroform. Knowing what I know now I would not give 4 per cent. of chloroform vapour for all the fees I get. And with the "increase tube" and a careful handling of the vessel one can give up to that through the Vernon Harcourt inhaler. I have not used it in 1000 cases but the cases I have used it in have been, as I said, fairly representative and I have not used the "increase tube" once. Several times accustomed to other methods I have felt that I must use it, but by attending to my business I discovered that was simply because I had not fulfilled the conditions of success.

I have no doubt but that Mr. Hilliard's instrument is an admirable one and I regret that I must say—judging from his lucid description and the picture accompanying it—I prefer something I can easily hold in my hand to an inhaler fixed on a board which has to be fixed under the mattress; something I can hang up near me to an instrument that needs a table *for its accommodation*; something that by its "click-click" tells me the respirations are all right and at a glance that oxygen as well as chloroform is reaching the lungs. For, as he truly says, "chloroform can never be quite safe." Is anything quite safe ever in excess? I am, Sirs, yours faithfully,

DAVID ANDERSON-BERRY, M.D., F.R.S. EDIN.

July 31st, 1905.

THE USE OF PHENYLHYDRAZIN IN THE EXAMINATION OF URINE.

To the Editors of THE LANCET.

SIRS,—I regret having overlooked the point to which Dr. P. J. Cammidge refers in THE LANCET of July 29th, p. 316. In his article in your issue of July 1st it certainly seemed to me that he was advocating the rapid method of using this test. I am aware that operating with aqueous solutions is not quite the same as is the case with a urinary solution, but even in this latter case I find that if 0·3 gramme of maltose or lactose be dissolved in 100 cubic centimetres of normal urine and the phenylhydrazin test be then applied, an appreciable deposit of osazone crystals results if the water bath be used, whilst boiling over the free flame for five minutes elicits no response at all. With regard to dextrose I have repeatedly found that if the urine contained but a very small quantity a positive reaction could almost invariably be relied on after 30 minutes of the water bath, but this was by no means the case with the rapid method. Further, I have had the same experience when using Dr. Cammidge's own test for pancreatic urine.

I am, Sirs, yours faithfully,

L. C. S. BROUGHTON.

Langley-green, Birmingham, July 31st, 1905.

TEMPORARY FIXATION OF AN IMPERFECTLY DESCENDED TESTIS TO THE THIGH.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Mr. C. B. Keetley's further account of his procedure as given in THE LANCET of July 29th, p. 279. I have no doubt whatever that an imperfectly descended testis has, in the great majority of cases, some value. If it lie within the abdominal cavity I believe it has a greater value than if it has been arrested in the inguinal canal or high in the scrotum. Seeing that one has so constantly to operate for the hernia, potential or actual, which is nearly always present, what should be done with the retained testis is a matter of moment. If it is of value it should not be removed. If it can be brought down into, and *kept* down in, the scrotum this has undoubted advantages. But there are very few cases in which this permanent position is attained. Mr. Keetley does not state in how many it occurred in his 25 cases, but merely "the testis generally remains permanently in the scrotum but near its root." I am not sure what is meant by the "root of the scrotum," but I am sure that a testis placed at the level of the root of the penis is little if at all better off than one in the inguinal canal. Again, Mr. Keetley asks the question, "Do these testes grow when brought down in the scrotum?" and he answers, "Undoubtedly some of them do but not to the size of normal testes." Again, he does not give numbers, and accurate statistics are what is needed on this interesting question. I, personally, have never seen a testis *increase* in size after being artificially brought one inch or so lower down—that is, into the upper part of the scrotum. If any have done so I do not believe that their forcible displacement has had anything to do with their subsequent enlargement. On the other hand, I have seen many testes both in my own practice and in that of other surgeons *diminish* in size after being pulled down. Further, I am at variance with Mr. Keetley when he says that a testis just below the superficial abdominal ring—that is, just below the inguinal canal—is in a comfortable position. My experience is that testes which have reached this position naturally, but have been arrested there, are very apt to be drawn up at times against and through the pillars of the opening, whereby much pain is caused, and that even when no actual hernia exists. To fix a testis artificially here is to leave it subjected to these pulls during the movements of the abdominal muscles and to leave the patient liable to intermittent suffering. Mr. Keetley has been fortunate not to come across such a condition. I have and have had several times to remove the testis for it. But if the testis is of value and cannot be satisfactorily brought down and should not be removed there is still another procedure which may be adopted. This is to return it, after it has been freed if necessary, within the abdominal cavity. I have never regretted doing this. The testis is placed, like the ovary, in a comfortable position, the inguinal canal can be completely closed, and there is only a mythical increased tendency for it to become the site of malignancy. I find more and more surgeons are adopting this simple method and with the most gratifying results.

I am, Sirs, yours faithfully,

Harley-street, W., July 29th, 1905. W. McADAM ECCLES.

THE TREATMENT OF FRACTURED RIBS.

To the Editors of THE LANCET.

SIRS,—The treatment of fractured ribs by strapping is probably less satisfactory to the patient than to the surgeon. From personal experience it seems so to me. When in South Africa I had three ribs and a shoulder-blade fractured. I was well strapped in routine fashion but was relieved for a short time only, the strapping only too soon becoming loose. Pain prohibited me from lying in bed, doubtless owing to the fractured shoulder-blade, at that time not diagnosed. It then occurred to me that fixation by something resembling a stays would be an improvement upon the old method. A simple binder on these lines made of stiff jean I had made, fitted to lace up at the back and tie in front. Shoulder bands (of tape) also to tie at convenience kept the binder in position. The objection naturally raised to this treatment would be that it was a restraint not only on the injured but also on the uninjured side of the chest and calculated to interfere with the breathing. As a subject of spasmodic asthma from early childhood I can only say that it does not appear to be so. The relief obtained from the home-manufactured stays was enormous and I had no dyspnœa. As far as the ribs were concerned the treatment was entirely satisfactory.—I am, Sirs, yours faithfully,

FRANK ELVY, M.R.C.S. Eng., L.R.C.P. Lond.

FREE MEALS, CLOTHES, AND MEDICAL TREATMENT FOR THE SCHOOL CHILDREN OF BRUSSELS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Brussels, July, 1905.

THOUGH the agglomeration of independent boroughs which is called Brussels is very small as compared to the metropolis of London, the city of Brussels is very much larger than the City of London. The *agglomération Bruxelloise* may count some 600,000 inhabitants, a third of whom live in the city of Brussels itself. It is not a third or even a thirtieth part of the inhabitants of the metropolis that live in the City of London. In any case, whatever the historic city of Brussels has done is a matter of importance throughout Belgium and often serves as an example for the whole nation. In view of the physical degeneration of certain sections of the population not only in England but in all industrial countries, and of the fact that on all sides there is a very general conviction that better care must be taken of the children in the primary schools, I have made some inquiries as to what has been done here. Unfortunately for many years Belgium has been distracted by a fierce conflict for and against clericalism. The cause of education has consequently suffered greatly. There are two sorts of schools—the "free school," managed by the priests, and the communal school, managed by the municipalities. About the latter every possible information is forthcoming; every farthing spent is accounted for and vital statistics are forthcoming so that some information is at hand in regard to the health of the pupils. As for the free schools, the less said about them the better pleased are those who are interested in their maintenance. It is only when infective disease exists among the pupils that the authorities have a right of entrance to these schools and this right is derived from the laws which the French Republic established in Belgium in 1793. In such circumstances the only information available that would be of use for anything like a scientific investigation is that supplied by the local authorities concerning their own schools. Education in Belgium, though widespread, is not universal and there are still a good many children who do not go to school at all. This is notably the case with girls who are frequently kept at home to help in the household work. Nevertheless, in the primary schools of Brussels much the same problems arise as those which have puzzled the education authorities in London and all the great industrial centres. It is evident, in Brussels as in London, that a certain number of children are insufficiently fed and are wanting in clothes, while others are absolutely deficient in health, stamina, and mental and physical development. It must further be recorded that in spite of the gravity of such a state of affairs no very heroic remedy has been attempted. Nevertheless, a good deal of steady work has been done, though reforms were introduced gradually and in detail and there has been no sweeping and sensational legislation.

A peculiar feature about such attempts as have been made is the fact that whereas in England the cry that the children must be fed has gone forth with swelling strength and volume, in Brussels it would seem as if greater attention is bestowed on the necessity of clothing the children. In any case the official reports show that during the school year 1903–04 the number of children frequenting the communal schools of the city of Brussels for primary, secular, and gratuitous education amounted to 13,994. From Nov. 16th, 1903, to March 26th, 1904, these children received 318,699 helpings of soup and 307,609 rations of bread. This was not given to all of the children but to 2691 out of the number or, roughly speaking, to one out of every five children. So that this might be done the municipality of the city of Brussels gave a subvention of £400. It also gave a soup subvention of £200 to the free schools—that is to say, to the clerical schools. It should further be mentioned that 679 little children attending kindergarten schools were likewise fed. On the other hand, and during the same year, no less than 2107 complete suits of clothes and 14,580 various articles of clothing were given to 7963 pupils attending the communal schools. Thus, putting the matter in round numbers, one out of every five children was assisted with gifts of food and one out of every two children with gifts of clothing. This is certainly very different from what is in contemplation in England where the question of clothes has scarcely been raised. A number of different charities and committees work to collect some of the money necessary to provide these clothes. Then when fairs are held the municipality charges the holders of booths, stalls, &c., a certain rent. A portion of the money thus received is devoted to the purchase of clothes for the school children. Moreover, the municipality supplies at the public cost raw material to the schools and the children are taught sewing, dressmaking, tailoring, and so on, by converting this material into clothes. In this manner 146 suits and 6771 different articles of clothing were made by the children themselves and were given to those among them who had need of these things. During the year various private charities supplied 1582 complete suits and 5428 articles of clothing, while 525 suits and 13,796 different articles of clothing were given by the municipality, that is to say, at the public cost. Still more was done for the little children who frequent the communal kindergartens. There are 3385 children inscribed and the average kindergarten attendance was 2848. Among these children private charity gave 218 suits and 2466 articles of clothing and out of the public purse they received 91 suits and 4224 articles of clothing. Private charity also distributed 3850 toys and 2649 gifts of sweets or of fruit to the kindergarten children. It cannot be said therefore that they have been neglected.

Perhaps the fact that the need of clothes is apparently greater than that of food may be due to the more orderly and economical disposition of the Belgian poor. Belgian women have more knowledge and skill with regard to their housekeeping than would usually be the case with a similar class of poor in England. It will then be easily understood that a well-ordered family, living on from 16*s*. to 20*s*. a week, may be able to give regularly the few pence daily required for each child's food but cannot afford an occasional outlay of several shillings to buy clothes. The parents might justifiably prefer to give sufficient food rather than to save money for the purchase of clothes. Thus in a well-kept household poverty manifests itself by the want of clothes rather than of food. This is possibly the reason why in Brussels more has been done in regard to clothing than to feeding the children. Doubtless if this clothing was not given and the parents were forced to spend the little money that they have in buying clothes, there would be more starvation among the children and consequently more food would have to be provided. So that the result would be somewhat similar in the long run.
